Introductory Address
ON
RESEARCH IN MEDICINE AND WOMEN IN RESEARCH.

Delivered at the Opening of the Winter Session, 1911, at the London School of Medicine for Women,

BY SIR HENRY T. BUTLIN, BART., D.C.L., LL.D., P.R.C.S.,

CONSULTING SURGEON TO ST. BARTHOLOMEW'S HOSPITAL.

LADIES AND GENTLEMEN,—I imagine that an Introductory Address a century ago afforded the hospital staff the opportunity of welcoming the new students and of giving them some idea of the scope and nature of the work which lay before them. And I have no doubt that the orator did sometimes tell the young men that the profession they sought to enter was a great and noble profession, and of an interest sufficient in itself to repay them for their labours. A hundred years ago there was ample reason for the address, for, once admitted to the school, the student was left much to his own resources.

REMARKS ON INTRODUCTORY ADDRESSES AT THE PRESENT DAY.

In these days the Introductory Address needs justification. What with students' numbers of the journals, what with resident colleges, wardens, tutors, and demonstrators, the student has no need of an address of welcome or of warning or of general advice. My own school (St. Bartholomew's) recognised this many years ago and abolished the Introductory Address; it has never regretted that it did so. But the custom still exists in most of the schools, and the orator, not being tied to the one subject, selects any subject which pleases him, usually without any reference to the opening of the winter session, or to the new students, except for a few words at the beginning or end of his address. In truth, it is difficult to find use or excuse for the Introductory Address in this twentieth century—except at the School of Medicine for Women, where the conditions are wholly different. The entrance of women into the medical profession, the foundation of this school, the success of women at examinations and in the honours' lists, the story of the pioneers who fought so bravely, the story of the positions which women have captured, the financial success or otherwise of the movement, the lines of practice which are likely to open to them, and a number of other subjects, all of which might perhaps be treated at another place or at another time, are nevertheless much more fitly treated here. The story of the struggle cannot be too often told to the students of the school. Nay, more, it is scarcely over yet, and those who may have to fight have need to be heartened up to wage the battle bravely. When I was invited to deliver the address I therefore accepted gladly—first, because I was very proud of the compliment; second, because your school, individually and collectively, has been more than kind to me; third, because, in the language of the day, I thought I had a "soft job" in hand. It seemed as if nothing could be easier than to select any one of the subjects I have mentioned and deliver an interesting address upon it, and I set the whole matter aside much longer than I ought to have done, for I have been heavily occupied this year. Finally, before deciding on the subject, I thought I would look through the addresses of the last 15 or 20 years to see what had been done. Imagine my dismay when I discovered that every conceivable and appropriate subject had been dealt with, and by persons who knew far more about each one of them than I could ever know. They were experts in them. They had borne a part in the fray. They had fought with purse and pen, if not with sword. And they had naturally been listened to, when they thought fit to speak, with that profound attention which the hero commands when he describes his own experience and offers advice and counsel which are founded on it.

When I discovered the trap into which I had fallen I was very sad. I had so earnestly desired to deliver an address which should be worthy of you—at least to offer you my very best. And it seemed that I had really nothing to offer. But about this time I attended a committee at the Lister Institute of Preventive Medicine. Visiting the laboratories after the meeting, I saw one or two women at work, and learned that they were engaged in research, and I wondered whether they were good at it. I had previously been introduced to a woman-worker in the museum of the British Medical Association last year in London and was pleased to find that some of the most beautiful microscopical exhibits had been prepared by her. The sight of these ladies interested me, and I thought I would find out whether medical research has been embraced by women to any large extent and whether they have succeeded in it or are likely to succeed in it. I am going to tell you what I have learned, but the information is very scanty and would not fill or justify an address were it not that I am anxious to direct the attention of medical women, both qualified and unqualified, to research in medicine, and that to do so will give me an opportunity of making some general remarks upon research in medicine.

RESEARCH BY OBSERVATION OR BY EXPERIMENT.

In my young days we spoke of such work as "original work," and very little encouragement was shown to it. At the present time it goes by the name of "research," and is very much in evidence and receives considerable support. The object of research is to discover something which was not previously known, or to correct or to confirm some previous observations. There are two methods of research—the one by *Observation*, the other by *Experiment*. In medical research the method by Observation is much out of fashion; it is slow and may be often interrupted for want of material. The imperfection of the material is often very disappointing. The method by Experiment (not by any means limited to experiments on animals), on the other hand, is the fashion of the day; it is quicker, less liable to be interrupted, and may yield brilliant results in a very short space of time. It is, therefore, naturally beloved of all young research workers. But it is a two-edged weapon, and needs to be used, and its results to be accepted, with great caution. Mr. Hunter, who was a confirmed and most ingenious experimenter, said in the course of his evidence at the trial of Captain Donellan: "I apprehend a great deal depends upon the mode of experiment; no man is fit to make one but those who have made many and paid attention to all the circumstances that relate to experiments."[1]

I should not trouble you with these remarks on the two methods if the young workers were the only persons who preferred experiment to observation. But it is quite otherwise. Within the last few years I was associated with Mr. Shattock, whom you know as a distinguished pathologist, in the selection of a pathologist who would be expected to engage in research for a well-known cancer institution. Mr. Shattock was insistent that the pathologist should be an experimenter, and gave me to understand that, in his opinion, clinical pathology was played out and that nothing more was to be learned from it, and that our knowledge in the future must be gained by experimental investigation.

INVESTIGATION OF CANCER.

Let me give you my experience of these two methods in the investigation of cancer. Many years ago there was great confusion in the minds of pathologists and surgeons regarding the differences and resemblances between sarcoma and carcinoma. I made a diligent study of them by observation of the cases at my hospital, the cases at other hospitals, and the cases recorded in the literature of many countries. The research was very long, very tedious, and very disappointing by reason of the small number of cases which were sufficiently recorded to be available for use. The results formed the subject of the Erasmus Wilson lectures 30 years ago, and proved that the life-history of the varieties of malignant disease does not depend merely on their structure, but upon their seat of origin, and that the varieties of malignant disease of every part of the body must be separately studied if they are to be treated with success. Observations of a similar kind have been made by other clinical pathologists, with the result that the most successful operations for cancer at the present time are based on the results of clinical pathology. For no part of the body has this been done with greater success than for the breast.

[1] Palmer's "Works of John Hunter," vol. i., p. 195. London, 1837.

217160

Charles Moore and Mitchell Banks urged the importance of very large operations many years ago, but surgeons fought shy of them because they lacked that which was supplied many years later by Heidenhain and Styles, a scientific basis. Recently, Handley has again added valuable information on the same subject, founded on clinical and microscopical observation.

I have never engaged, personally, in experimental investigation on account of the difficulty of doing so 30 years ago. But I have been associated with the Imperial Cancer Research, and in touch with its staff from the foundation of the Research, and have been a member of the Publication Committee of all its scientific reports. It has done nothing on the lines in which observation has been so useful. It has not unfolded the life-history of a single variety of cancer so that we can base our operations on the information. It has not even discovered whether spontaneous cancer of a particular part of the body in the rat or mouse runs a similar course to spontaneous cancer of the same part of the body in the human subject. These problems are not suited for experimental investigation: they are determined by observation. On the other hand, within the space of eight or ten years it has definitely settled a matter of dispute which was discussed and fought long before I became a student, perhaps for centuries. It has proved, beyond the possibility of doubt, that cancer in its early stages is a local, not a constitutional or blood, disease. It is impossible to overrate the value of this knowledge to the surgeon. So long as he believed that cancer is in the blood and that an operation only removes the local manifestation of it, he was hopeless of the results of his operations, and removed the tumour solely to afford the patient temporary relief. Now he goes to his operation filled with hope that, if the disease is limited and in an early stage and his operation is well designed and skilfully carried out, it may be quite successful. Thus, it will be seen that the two methods, *observation* and *experiment*, have their special values in relation to cancer, that each is supplementary to the other, and that neither is fitted to take the place of the other.

THE QUESTION OF UTILITARIAN OBJECT.

It will be noticed that I have dwelt on the use to which these researches have been put in the treatment of cancer and of the value of them to human beings. You may fairly think these ought to be the immediate objects of all research in medicine and that researches which are not likely to be immediately useful should be discouraged. But while I freely admit that my sympathy is in favour of this view, I am bound also to admit that it is wholly erroneous. I have fought this question on the platform at the annual meeting of the British Medical Association on several occasions and referred to it again in July of last year, and I shall not repeat the arguments which I used or the examples to which I referred. I would merely say that the investigator should be solely interested in discovering the truth, and that his attention should not be diverted and his judgment warped by the desire that his research should terminate in a particular manner because that might seem likely to be more useful to medicine and surgery. It is notorious that some of the researches which have seemed to fulfil no useful purpose have yielded the most valuable practical results, while other researches, pursued with a useful end in view, have furnished nothing good. If a utilitarian value were considered essential to research many young investigators who have later produced the most brilliant work would have been choked off and discouraged, so that they might never have persevered in original research. I need only give two illustrious examples, Pasteur and Lister.[2] Their first researches had no utilitarian object. What a lamentable thing it would have been if they had been discouraged from research on that account. The great thing is that young people who are fitted to do so should be encouraged to search. What they search for is of comparatively small consequence. On the other hand I would not have it supposed that a utilitarian research is derogatory to the dignity of the worker or necessarily damages his *morale*. Sir Humphry Davy deliberately worked out the problem of coal-gas and explosions, and invented a safety-lamp at the urgent request of the coal-owners. Professor Pasteur investigated the nature of the pébrine disease of silkworms at the request of M. Dumas, and moved by pity at the wretched condition into which the silkworm industry had fallen. He discovered that it depended on a parasitic protozoon and devised a successful method of stamping it out.[3]

[2] The first researches of Pasteur were on the crystallisation of tartaric acid and its salts. The first researches of Lister were on the contractile tissue of the iris and on the muscular tissue of the skin.

COST OF RESEARCH.

Just a few words on the cost of research. Dr. Leonard Hill[4] pointed out some years ago what great results could be achieved by an able worker with the simplest materials and at the smallest cost, and that fine laboratories and costly apparatus are not essential to research in medicine. All this is very true, just as it is true that David killed Goliath with a stone cunningly hurled from a sling. I do not think David at the present day would sally forth with a sling to oppose a foreign host. And our profession is continually urging on the wealthy public the financial claims of research. In order to justify our demands let me give you two concrete illustrations of the cost which attends certain researches. The Imperial Cancer Research is provided with laboratory accommodation, free of rent, by the two Royal Colleges. I think we also provide heat and light and water. But the annual cost of the research, including salaries and wages, amounts to little short of £6000 a year.

A rich man of business who is interested in acoustics in relation to the human ear found that his views could not be proved unless he possessed accurate measurements of the dimensions of the cochlear passages of the ear, and that no such measurements have been recorded. In the course of last summer he wrote to ask me whether the Royal College of Surgeons of England would administer a certain sum of money which he was prepared to supply for the research and referred me to our conservator, Professor Keith, for information on the subject. Professor Keith told me it was quite a proper subject for research, and advised that my old pupil, Mr. Sydney Scott, should superintend and direct it. I was disposed to recommend the Council of the College to accept the trust. But, before doing so, I thought I should like to know whether the sum proposed by the gentleman was likely to cover the cost. If it would not, we should then be obliged to abandon the research without having obtained any tangible result, or the College might have to complete it at its own proper cost. It was well I inquired. Mr. Scott made a rough estimate for me. The material would really cost nothing. But the research involved the cutting of an immense number of sections of the bone by an expert workman, and Mr. Scott only knew one workman in London whom he would care to entrust with the work. If a single section went wrong, all the other sections made from that bone might be useless. Every fourth section must be drawn to scale. Moulds would have to be made, and this could be done only by an expert. Finally, an exact model, mathematically correct, would be constructed. Mr. Scott estimated that this research, which I had thought quite simple, might require one year or two years to carry through, and that the cost would not be likely to be less than £1000.

QUALITIES NEEDED IN AN INVESTIGATOR.

In order to determine whether women are likely to be useful and successful in research it is necessary to consider the qualities which should be looked for in an investigator—I mean, in an investigator who has the sole charge of a research, even though it be carried out in a laboratory where other persons are at work. I am not speaking of an expert assistant or even of a joint investigator.

For (1) experimental research (including experiments on

[3] Histoire d'un Savant par un Ignorant. 5me édition. Paris: J. Hetzel et Comp. P. 173. "Le Sénat fut saisi d'une pétition désolée, signée de trois mille six cents maires, conseillers municipaux et propriétaires fonciers des départements séricicoles. La grande autorité scientifique de M. Dumas, sa connaissance de l'industrie de la soie, sa sympathie pour les souffrances d'un des départements les plus frappés,—le Gard, son pays natal,—tout contribua à le faire nommer rapporteur de la commission. Pendant qu'il rédigeait son rapport, l'idée lui vint d'engager M. Pasteur à se livrer à des recherches pour conjurer l'épidémie dont personne ne pouvait triompher. M. Pasteur commença par décliner cette offre."

[4] Brit. Med. Jour., 1907, vol. i., p. 960. "Men of science are not made by institutes, money, or apparatus. Helmholtz did his best work on £120 a year, and modelled his inventions out of spectacle lenses and his wife's sewing gear. Faraday did his epoch-making work with bits of wood, glass, and wire. Claude Bernard filled his pupils with enthusiasm in a laboratory little better than a cellar."

animals) I should set down: dexterity and neatness in manipulation; a knowledge, not only of the principles, but of the practice of aseptic and antiseptic surgery; and certainly humanity, so that the experiments which are necessary should be performed with as little suffering to the animals as possible.

For (2) every kind of research I should look for personal cleanliness; cleanliness of habit; industry, which must be extended to mean continued industry; patience, and a large stock of it; perseverance, and a determination to pursue the research to the end; extreme care in observation and strict attention to detail; careful recording of observations, which should be done at the earliest possible moment; thorough belief in the importance of the particular research, amounting even to enthusiasm; conscientiousness.

Many of these desirable qualities will at once commend themselves to you: they need no more than enumeration. But you may wonder why I have set down others of them. For instance, what has cleanliness of habit to do with research provided the investigator is cleanly when at work? Well, preserve me from investigators of careless habits. How many years ago—not very many—is it since poor T—— slew himself, a servant in his mother's house, and a laboratory attendant owing to his slovenly habits? He was a distinguished classic at his university, had been a coach there, entered medicine when he was nearer 30 than 20, qualified with ease, and then settled down to make a reputation. We all liked him, and wished him well, and when he desired to engage in research encouragement was given him. Unhappily, nothing would do but he must study the bacillus of typhoid, the last thing which should have been entrusted to so slovenly a person and so clumsy a manipulator. He used to carry his cultivations of bacilli in his lunch basket, save the mark, with the disastrous finish I have described.

Again, what has conscientiousness to do with research any more than it has to do with any other of the affairs of life? Do I mean that an investigator should be honest and not appropriate or use unfairly the work of other investigators? Oh, no! I assume such honesty as this in every investigator. The conscientiousness of which I speak is of the worker to himself and his own work. In this way. A worker has been engaged in a research during many months. He has made many experiments and observations, and they have all gone to prove the correctness of the result at which he has arrived. But there is still one experiment which it would be well to try. He tries it, and curiously it does not turn out quite right. He put two and two together and they did not make four. And everyone agrees with "The Professor on the Case"[5] that two and two do make four, "not *some* times but *all* the time." Now is the moment when his conscientiousness should come into play. The temptation is overwhelming to explain the failure by some fault in technique, and to set the result of that experiment on one side rather than to repeat it again and again as he ought certainly to have done. Had he done so it would again have failed, and he would have learned in the end, not that two and two do not make four, but that one of his twos was not a two, and he would have avoided publishing that result of his research which was afterwards discovered to be incorrect by a more careful and conscientious worker. It must always be borne in mind that the mischief of a faulty result does not end with that research, but may be the starting point of a long series of equally faulty results.

FITNESS OF WOMEN FOR RESEARCH WORK.

Now, do women possess these qualities? I think so; many of them, indeed, in a higher degree than men do. Humanity, dexterity in manipulation, cleanly habits, continued industry, patience, perseverance, attention to detail: all are truly feminine qualities. Indeed, there is only one point on which I am not certain, and I express myself upon it almost reluctantly because my doubts are founded on information regarding the ways of women which it is mean of me, perhaps, to use. There is nothing more important in relation to research than the accurate recording of observations and experiments. The making of these records is very tedious; it is often inconvenient to make them at the moment, and yet many of them must be made then if they are to be relied on. Nothing is more wonderful, to my mind, than the extraordinary care which is devoted to this part of their work by the greatest investigators. Read Lord Lister's "Collected Papers"[6] and you will see that I am right. Tyndall tells that Faraday left private notes of more than 16,000 experimental researches.[7] Many men fail in this respect, largely from lack of patience. If women fail, I judge that it will largely be from lack of training. It has been told me that the lady secretaries of committees and business meetings are often astoundingly inaccurate in their minutes, that their record of those present cannot be relied on, that resolutions which were passed are not properly worded in the report, and I have even heard of minutes which recorded the wrong person in the chair; and what surprised me more than any other thing was to learn that when these inaccuracies are pointed out the secretary considers herself the aggrieved person. I am not speaking of uneducated persons, but of highly trained and even scientific women, and I wonder whether such people could ever be trusted to conduct and record an investigation. We men take these matters more seriously. Such lapses are not tolerated among us. It is of no consequence whether a secretary is paid or unpaid; he may be indolent and make very meagre records. But what he does record must be accurately recorded, and the only way to do so is to write the minutes at the time or to make ample notes from which they can afterwards be written up. We have been trained in this kind of work for centuries, and I expect it has become a part of the nature of men.

EXTENT OF RESEARCH BY WOMEN WORKERS.

Seeing the fitness of women for research, I hoped to find a good many of them at work. I can scarcely say it is so. The British Medical Association, as many of you know, awards about £300 a year in various sums to assist research workers to buy material and apparatus, but not for maintenance. The first award was made to a woman (Miss Julia Brinck) in 1890. In the 20 years since that time there have been awards to only three other women workers, and the amount of money which has been awarded to women has been £65 out of probably £6000 to £7000 total award. I do not think this is the fault of the Association, for it has always been very well disposed towards women workers. Only once has a research scholarship of the Association been held by a woman (Miss Janet Lane-Claypon in 1904), and she only held it for a year, I think because she was not qualified. But I am told that her work was so good that the committee expressed the wish that she would apply again as soon as the necessary conditions had been fulfilled.

The Brown scholarship at Cambridge (for research) has once been held by a woman. And at the present time three of the Beit Fellowships are held by women. Apart from the Mabel Webb and Helen Prideaux scholarships, which belong to your own school, and which are not sufficiently well endowed to maintain the investigator, and which can, therefore, only claim part-time work, very few research scholarships which are open to men and women have been held by women. On the other hand, there are very clear indications that the attention of women is being directed to research, and there is proof that committees and trustees are disposed to consider their claims favourably. The Brown scholarship was awarded to a woman only as recently as 1909. Twelve women applied for Beit Fellowships, and three of them have been appointed—one in 1910, the other two this year. The Worshipful Company of Grocers has quite recently permitted women to apply for its two research scholarships (each worth £300 per annum). One woman has already applied, but her application did not fulfil the essential conditions. I trust this address may direct the attention of women still further towards research work.

I have no doubt I shall be asked whether I believe that women will be found competent for research, whether they have the breadth of mind necessary for such work, and whether they will ever be able to do more than carry out researches which have been designed for them and in which

[5] "The Professor on the Case," Jacques Futrelle (T. Nelson and Sons), p. 25.

[6] "The Collected Papers of Joseph, Baron Lister." Oxford, 1909.

[7] "Faraday as a Discoverer," new edition, London, 1870, p. 182. "His mode of keeping accounts excited the admiration of the managing board of this institution (the Royal Institution). And his science was similarly ordered. In his experimental researches, he numbered every paragraph and welded their various parts together by incessant reference. His private notes of the experimental researches, which are happily preserved, are similarly numbered; their last paragraph bears the figure 16,041."

they are directed. Indeed, I do not know. They have done so many things in the last 30 years that I never thought they could do, that I would not on any account venture to predict what they will accomplish in research. But I should certainly like to see them try.

Introductory Address
ON
LUCIDITY.

Delivered at St. George's Hospital Medical School on Oct. 2nd, 1911,

BY H. A. MIERS, D.Sc., F.R.S.,
PRINCIPAL OF THE UNIVERSITY OF LONDON.

GENTLEMEN,—Some of the most difficult problems in education are those connected with professional training, and as time goes on these do not tend, I fear, to become more easy. The requirements of the professions become every year more exacting; if the student is to get to work on the business of life before his grey hairs appear he is driven to begin his professional training earlier and to compress more and more into the few years at his disposal. And so it becomes increasingly difficult to secure in addition that general education which everyone knows to be so desirable—that introduction to the world of literature, science, and art which ought to be more useful perhaps to the medical man than to the member of almost any profession.

I confess that up to the present time medical men have held their own in a marvellous manner as students and exponents of all that makes up general culture, and that judged, at any rate, by the standard of their leading men they have managed to keep their wider interests and activities flourishing and fruitful in spite of the exacting calls of a strenuous profession and the years of very special study by which it has to be preceded.

If I may quote only one example of local significance, the annual exhibition of paintings by the St. George's Hospital staff used to give abundant evidence that even within the walls of a single hospital quite a number of accomplished physicians and surgeons may prove themselves to be equally accomplished as artists. But whether this is to continue, whether the increasing pressure of professional training, and the overcrowded nature of the school curriculum which comes before it, are not going to rob the medical man of some of his literary and artistic interests and powers, I should not venture to predict. The serious business of fighting disease, and the necessity of mastering all the weapons with which the never-ceasing contest is to be waged, are making the medical man's life one of such grim earnest that he will perhaps have in the future even less opportunities than he has now for those more refined studies and pursuits that presuppose some leisure and freedom of mind.

I wish, however, on the present occasion to draw attention to one feature of modern school and university life that represents a more serious defect, or at any rate the danger of a defect, in the medical profession; and not only in this, but in the other professions; may be not only in professions, but in all walks of life. It is, perhaps, not a matter of serious importance to the world at large whether a medical man can give expression to his ideas with the brush or pencil, provided that he be sufficiently learned and accomplished in the exercise of his calling; he is not necessarily a better doctor because he possesses and can exercise this artistic gift; neither is it necessary that he should have the powers of expression of an author or a musician. But there is need of one power that is as important to him as to others, and that is the ability to express his meaning in the written words of his own language, the great power resulting from mastery over the pen.

LACK OF CLEARNESS IN WRITTEN LANGUAGE AND ITS CAUSES.

I am led to choose this as a subject on which to address you, not merely from the want of anything new to say, but because it has been borne in upon me as a serious matter by the reports of some of our examiners in the University of London. They say that in medical examinations and even in the M.D. examination an essay or thesis is often not only devoid of any literary quality or finish, but is badly constructed and difficult to understand. If this can be so at the end of a man's university career, what must it have been at the beginning, and is there any chance of its becoming any better as he grows older? I do not think that the fault is entirely that of the candidates themselves. Whatever subjects they may have learnt at preparatory or public schools, the writing of their own language has in general not been one of them; even during their university career the use of the written English language, except as a machine for the taking of notes, or the answering of examination questions, or the bare record of work done, has not formed any regular part of their course.

The proper teaching of English at school is a large and important subject, and one on which I do not propose to enter at present; the acquisition of a good literary style is a luxury to which all cannot aspire; to which, indeed, comparatively few can attain; but the power of expressing clearly one's own ideas in one's own language is a thing which ought now to be within reach of every English-speaking man and woman. That so many of us do not possess it, even those who are quite well educated and accomplished persons, is due, I think, not so much to the fact that we have not been properly taught as to the fact that we have not been encouraged to teach ourselves. To me it has always seemed remarkable that while there are few who fail to express their meaning intelligibly by the spoken word, there are so many who fail to be intelligible when they write. The two faculties seem quite disconnected, and there is apparently nothing which necessarily makes the same person a good speaker and a good writer. Among those who are inarticulate in speech, and little able to convey their meaning in simple straightforward sentences, are to be found some both thoughtful and learned persons to whom writing seems the only proper and easy medium of expression. And, on the other hand, everyone must be familiar with examples of clever and accomplished speakers who lose all their power of expression when they write. And, more strange still, mastery over another language and ease of diction in a foreign tongue may exist side by side with the inability to write or to speak clearly in the mother tongue. I have known Englishmen who could be trusted to write a more intelligible treatise, possibly even to make a more lucid speech, in Latin than in English. Quite seriously, I think some part of the cause is to be sought in the difficulty of our language, and many educated persons get lost in its intricacies just as they get lost in its spelling. One must, of course, realise that the same wealth of vocabulary and variety of construction which make the language difficult bestow upon it the greatest possibilities in the matter of style. But for this very reason I do not believe that the remedy for the defect of which complaint is made is to be found in the imitation of great authors.

INUTILITY OF STUDY OF GREAT AUTHORS.

It is often assumed that constant reading and imitation of the great masters of English literature will enable one to acquire a style which is good because it is based upon theirs. John Bright and Professor Tyndall, to mention only two among many, attributed much of their own command of language to the fact that they had early in life been made familiar with the English Bible and the works of Milton, and that they had maintained their knowledge of these masterpieces of style through life. But I think it will be found that they had both already, by another process to which I will presently direct your attention, acquired the power of expressing themselves in straightforward English, the one in speaking, the other in writing, at an early stage of their career; and it is to such persons, already so equipped, that the profound and unceasing study of the great authors brings an increasing mastery over the difficulties of the English language. To introduce a child to the great masters of style with the injunction that he is to learn to copy them and by so doing to acquire something of their power, is like expecting an artist to acquire the power of expressing himself by nothing but a course of copying in the picture galleries without independent effort. Listening to good music will not make a musician.

Although the systematic study of great authors is usefully pursued at schools, yet the usual methods of teaching English still leave the average boy and girl singularly deficient in the art of saying what they mean on paper. Now

people like ourselves, who have more or less finished our education, are not going to get very much more out of it than children, who in these matters are far more ready and apt pupils than ourselves, being of course more imitative and quicker to learn. Except to those who have already acquired in some measure the faculty of expressing themselves *in their own way*, indifferent though that may be, I do not think that the mere study of authors who possess a great style is going to confer upon the ordinary reader any great power to express himself in the manner of those authors.

I am inclined to believe that the attempt to write good English is to many a person an effort that only makes him sink the deeper into the quicksands of unintelligibility. For think what this effort means. Analyse the style of Ruskin or Stevenson, of Macaulay or Burke, of Pater or De Quincey; how is a reader who has not yet learnt to make himself intelligible to improve matters by imitating the delicate shades of expression, the fine suggestions, the haunting echoes, the persuasive rhythm of their sentences? Any one of us may admire the consummate skill of such authors just as we may admire the workmanship and the art of a painter without being able to paint a stroke ourselves; or still more easily perhaps the beautiful creations of a musician although we cannot write a note of music. Before even the young artist who possesses some natural gift can emulate these, he must go through a long apprenticeship. And our great authors are artists in words whom it may not even be desirable for us to emulate. For the difference is that whereas we cannot all be painters and musicians, but must content ourselves with remaining intelligent admirers and critics, we have perforce all to be writers, whether we wish it or no, and our writing will be necessarily either good or bad or indifferent.

How to Learn to Write Clearly.

What, then, is the necessary foundation which I have been so long suggesting without naming, which is to be secured as the basis before the delicate structure of good style can be firmly erected? It is simply this—that we should think about expressing our own meaning in absolutely clear and intelligible language before we think about the manner in which that language is to be manipulated or the style in which the meaning is to be conveyed. To express some thought of one's own in language which cannot be misunderstood and which makes it quite clear to others is an extremely difficult task; it is one of the things which is least satisfactorily taught at school and at the university; it is one which has been least effectively acquired by most people among all the necessary things that they have to do in life. You have only to read carefully the letters in the newspapers from people who write both, I presume, because they think they have something to say, and because they think they can write, to be convinced that what I say is no exaggeration. And then think of the thousands of people who do not write to the newspapers, and in fact do not write at all if they can help it, because they know that they are not able to do so with any credit to themselves.

One of the best educational exercises possible in the use of the English language is to take one of these letters and analyse it, and show a child, or for the matter of that a grown person, how it fails to make its meaning clear, how in some cases the words may have two meanings and in others no meaning at all. Let me quote a recent example from a daily paper. "It surely should not be possible for an individual to destroy the trade of a town with which he has no connexion other than as the organiser of a society claiming a general right of interference by practically compelling the permanent closing of industries in which there was before his coming, no actual dispute or necessity for interference except in virtue of this society's claim." I have purposely chosen a sentence in which there is nothing really wrong except that it is not clear, so that you must read it at least twice before you can discover what it means. But this is, after all, only criticism, and, as I have said, we are condemned to be not only critics but users of words. And so a much better educational exercise is to get your pupil to write something of his own, and to criticise that in the same manner. Only so will he understand the difficulties by practice and learn to profit by experience. Some of the best learning in the world is done by making mistakes, and in no subject is this method so effective as in the writing of one's own language.

Defects of Present System of Teaching Composition.

How is the practice of composition actually taught? Set essays are written and corrected, or a subject is prescribed and the pupil's account of it is criticised. But I suspect that the criticisms are more often directed to the wrong use of words, to faults of grammar, to defects of style, than to the question of prime importance—namely, intelligibility. And yet a split infinitive is really a far less important fault than a failure to express one's meaning. Translation ought, one would think, to be a good exercise, for here an effort is made to interpret the ideas of a foreign author into one's own language; yet translation fails to a large extent, because, after all, they are the ideas of another person which the pupil is called on to express. And so the result is that more attention is paid to the style and the manner than to the intelligibility, and a generation grows up that has never been called upon to make its own meaning clear to anyone. This result is particularly to be feared and is particularly noticeable in professional training. I can assure you that I have recently had appeals both from young officers in the army themselves and from others on their behalf asking how and where they are to learn to write clear and intelligible reports. For reports they have to write in the exercise of their profession, and these, if they are not clear, fail, of course, in the whole object and purpose of a report. Too late have such persons found out that they have never learnt how to express themselves in simple and clear language. Surely this is the very thing that should have been learnt in early school days.

And now we hear the same complaint from the examiners of medical candidates. The difficulty is particularly acute with those who, like yourselves, have received a scientific education. I have actually heard teachers and examiners in scientific subjects say of a pupil or examinee that he evidently understands what he is trying to say, but is merely unable to express his meaning. And then they have given him full credit for the knowledge and pardoned him the failure to express it. But surely to be inarticulate on paper is as bad as to be inarticulate in speech. And I can never believe that the man whose ideas are clear can be permanently incapacitated from expressing those ideas intelligibly with his pen. If, however, our scientific teachers and examiners do not insist upon the clear expression of scientific statements which ought more than anything to lend themselves to clear exposition, perhaps the fault is to be laid to their charge. The quality which I believe we have to seek, one which is so little fostered by our present system of teaching English, is, to put it in a single word—Lucidity.

Lucidity in Great Writers.

Among the great writers, those who impress us most both by what they have to say and by the manner in which they say it, are those who possess this admirable quality of lucidity. As two pre-eminent examples among the moderns, I may mention Cardinal Newman and Charles Darwin—in very different ways; for in the one it amounts to the highest perfection of style, while in the other it appears to involve rather an absence of style. Newman's limpid passages with all their grace possess the very essence of clear and lucid exposition; analyse any one of these passages and it appears to exhibit nothing but the most direct simplicity. If this be art, it is the art of a Duse which is almost indistinguishable from unaffected nature. He who possesses such lucidity may graft upon it the style of Milton, or Gibbon, or Ruskin, or Burke, and not much will be either gained or lost; of course, a beautiful style confers an additional charm upon all writing; and a page of Newman is better reading than a page of Darwin.

I am aware that lucidity is a word which was originally applied to the mind and only subsequently to literary expression. When the shadow was lifted temporarily from the clouded mind and the sunshine of reason returned it was said of the patient in the old legal phraseology: "Non est compos mentis sed gaudet lucidis intervallis," and the history of the word is instructive, for it is still the lucidity of mind which has to come before there can be lucidity of expression. There cannot be clear writing without clear thinking; and he who learns to write clearly will in the process learn to think clearly.

Necessity of Intelligent Self-criticism.

Now if I have, up to the present, done little more than deplore the absence of this quality, I do not mean to imply

that the only remedy lies in a reformation of our methods of teaching English at school, highly desirable as this may be. I believe that lucidity of expression is one of those things which can be acquired without teaching and by learning alone; further, that the only learning necessary is constant practice accompanied by intelligent self-criticism. We are too apt to be satisfied with the words in which we express ourselves without pausing to think whether they are intelligible. Take something which you have written and show it to any candid and discerning friend for his criticism, and see whether he does not find in it some flaw that is not at first apparent to yourself. He will tell you the same story as the examiners who look over your thesis, that the words do not say what you mean, and that the expression is in some way or other loose and unintelligible. It is very difficult at first to criticise what we have written ourselves—but the faculty is soon acquired. In ordinary life—since it was not made necessary for us at school—we have so little practice in this useful art. The only occasions when most of us have to weigh our words carefully in order that we may be quite sure that they will not be misunderstood are when we have to compose a telegram, or to draft a resolution or an amendment at some meeting; and everyone knows how difficult this is. Believe me, the same care is really necessary in anything that we write if it is to stand the test of criticism. The most wholesome experience of all is to have written a book, or an article in a journal, and to see your words staring you in the face in print and to realise too late how inadequate they are, and that they remain in print to condemn the author for all time. For the rest, the hasty letter is all that most people have in the way of practice, and the telephone is rapidly making this less and less necessary.

I have said elsewhere that the reason why our grandfathers and grandmothers could express themselves so much better than ourselves is, in my opinion, the fact that they had so much more practice in letter-writing, and that the letter was so much more important in their day than in ours. With the disappearance of the long, infrequent, carefully written letter, which would often be criticised at its destination by many eager readers, a great field of literary practice has been removed and has had no successor. If this be true—and it is the reason why I have been led to believe that the present defect is chiefly due to want of practice—then the remedy is simple: constant practice in careful writing. It is this which makes most people more ready with their tongues than with their pen; they get more constant practice in speaking than in writing, and they are liable to be constantly called upon to explain themselves if their meaning is not clear. If this check were always ready to be applied to all that is written as to all that is spoken half the difficulty would disappear.

VALUE OF CONSTANT PRACTICE IN LUCID WRITING.

It has always seemed to me that one of the chief reasons why practice is so necessary in both speaking and writing is that the thoughts flow at so different a pace from that of speech or the pen. Many inexperienced speakers are constantly being tripped up in their words in the endeavour to keep pace with their own thoughts, trying to retain a hold upon the swift thought while they are following it in less rapid speech. If this be so with speaking, still more must it be true with writing, where the hand and pen lag behind at a yet greater distance. I confess that writing has always been, and is even now, a slow, clumsy, and laborious process for getting a permanent record of our swiftly moving and evanescent thoughts, and that there is need of something better; it may be that the phonograph and dictaphone will ultimately make it unnecessary to transcribe in our present slow and laborious fashion, and I for one would welcome any scientific inventions which will make it easier for our recording instruments to keep pace with the mind. But I venture also to believe that for accurate thinking it is not a bad thing to have this drag upon the brain, and that to school the mind to keep pace with the pen is an excellent training for exact thought. And so I return to my suggestion that in order to remove this reproach from which the present generation suffers, which attaches particularly to professional students, and not least among them to medical men, we have to exercise ourselves constantly in the practice of lucid thinking by exercising ourselves in the practice of lucid writing. Schools and universities have their debating clubs and societies in which anyone can get valuable practice in speaking, and learn by experience to express himself fluently and clearly, and suffer for his sins if he does not do so. It is a pity that there are no societies which give a young man precisely the same valuable training in the use of the pen; and if any school or college will introduce a fashion for this sort of thing I believe that a great public service will be done. There was a time when the magazines were addicted to symposia, and induced prominent authors to take part in a written discussion on some topic of general interest; then one could at any rate see how accomplished masters of the art could wield the pen. A better thing would have been for the readers to do it themselves, just as it is a better thing to play cricket and football than merely to look on at cricket and football matches. Failing this, there is a course which everyone may easily pursue, and that is to get in the habit of seeing that every sentence which he is called upon to write is lucid; and the best way of acquiring this faculty is to keep what you have written and read it again in the cold light of reason, and when your mind is not full of the subject as it was when you wrote.

Most of the failures to be lucid are due to the habit of confusing what we think with what we write, and to imagine that because a thing is in the mind it is also on the paper. It is a common experience that in some respects and for the minor errors an author is the worst person to correct his own proofs; he knows what he meant to write, and he actually thinks that it is there and fails to see the mistake. In the same way each man is a bad critic of his own writing. This is the reason why I began by suggesting that you should first get a candid friend to be your critic; and, failing him, this is why I suggest that you should read the written page at some time when you are not biased by thinking of the subject rather than the manner in which it is expressed.

SCIENTIFIC WRITINGS.

The worst sinners of all are some of the scientific writers, and it is a standing reproach to science that at this period of its existence it is marred by so many ill-written, ill-constructed, and unintelligible books and papers. It was fortunate that in the earlier days of the great movement in the last century science enjoyed the aid of so many excellent writers. Davy, Faraday, Lyell, Darwin were such clear thinkers that they could not fail to be clear writers; but it was well also that somewhat later the public ear was caught by such graceful and skilful writers as Tyndall and Huxley. With them we find lucidity coupled with the graces of style, and since their day there have been many accomplished authors who have managed to make a text-book or an abstruse memoir delightful by their powers of expression. Even a mathematical text-book may charm by its manner—witness those of Dr. Salmon, who was equally accomplished as a mathematician and a theologian; and Clerk Maxwell showed in his little book, "Matter and Motion," how the most advanced mathematical reasoning can be expressed in the most simple and lucid language. In the same way was not Gladstone able to invest a Budget speech with a certain literary charm?

Among scientific books it is, curiously enough, some of the translations which fail most ignominiously in the attempt to be lucid. Let me quote an example from the translation of a very well-known text-book which in its original language is quite clear and intelligible.

> The successful scrutiny of the student of nature reveals itself in finding out that which phenomena, apparently very diverse, have in common, and the results are the more brilliant, as the parallelised phenomena appear at the outset more diverse. The transference of observations from one case to another is naturally at first attended with some uncertainty, but with the repeated corroboration of the experiences in question there follows an ever-growing credibility until this transference finally attains to the rank of an empirical law of Nature.

I believe this simply means that a law of nature is exhibited by comparing different natural events and finding what is common to them. The meaning of the sentence is entirely obscured by the introduction of unnecessary words. You will see that the fault here and in similar instances, which might be quoted by the hundred, is that the translator in the endeavour to make his version sound well, knowing that the sense has been provided by the author and that he is not responsible for that, has even inverted the perverted maxim of "Alice in Wonderland," and adopted for his

guide, "Take care of the sound and the sense will take care of itself." Rather than incur the danger of falling into such bad habits let us, with Berowne in *Love's Labour's Lost*, decide to express ourselves, "In russet yeas and honest kersey noes."

In the days of the scientific revival of the nineteenth century the great expositors who wrote with such admirable lucidity did much to facilitate the introduction of science into ordinary education, for it appeared, as indeed was really the case, that the accurate habits of thought encouraged by the study of science found their expression in this clear writing, and this led many people to see that the study of science, like that of philosophy, is an education in clear thinking. But now that much of the scientific writing is so badly expressed there is danger lest the opposite conclusion be drawn, and the impression is conveyed that the studies which lead to such loose writing cannot really be conducive to accurate and clear thought.

Let me, then, in the interests of science in general, and of medical science in particular, if it is to earn the respect of the multitude, in your own interests if you wish to acquire habits of exact thought and so to become leaders in the advance of medical science, repeat my suggestion that you should by constant practice in everything that you write, by constant and critical inquiry whether its meaning is clear, cultivate the desirable quality of lucidity.

Introductory Address
ON
THE MIDDLESEX HOSPITAL OF TO-DAY AND YESTERDAY: A BIRD'S-EYE VIEW.

Delivered at the Opening of the Winter Session at Middlesex Hospital on Oct. 2nd, 1911,

BY COMYNS BERKELEY, M.A., M.D.,
B.C. CANTAB., F.R.C.P. LOND.,
OBSTETRIC AND GYNÆCOLOGICAL SURGEON TO THE HOSPITAL, ETC.

YOUR ROYAL HIGHNESS, YOUR SERENE HIGHNESS, LADIES, AND GENTLEMEN,—Twenty-four years ago I entered this hospital as a University student and heard my first Introductory Address. What struck me then was the entire absence of any reference to the history of the place I had joined. I was told that this was the great day of the year. I remembered that at Cambridge *our* great day had been Founder's Day, on which year after year through centuries a brief history of the College had been recited and its benefactors extolled, but the lecturer on this occasion evidently did not think the new students would be sufficiently interested by some similar recital. As this deficiency has not been rectified by any of the succeeding 22 addresses I have listened to, I propose this afternoon to give you a bird's-eye view of what has happened to our hospital during the past 166 years.

FOUNDATION OF THE MIDDLESEX HOSPITAL.

Up to the year 1720 there were only two hospitals in London—St. Bartholomew's, founded in 1123, and St. Thomas's, founded in the reign of Edward VI. In 1720 Westminster Hospital was established; in 1721 Thomas Guy built his famous hospital in the Borough; in 1733 St. George's was erected at Hyde Park on the outskirts of the town; and in 1740 the London Hospital first took shape in Whitechapel Fields. It thus came about that the several parts of London were supplied with a hospital except one, and that was the district of St. Giles and Soho, a thickly populated quarter "abounding with poor objects." The inhabitants of this quarter therefore decided to found a hospital for the relief of their sick and lame, and in August, 1745, two houses in Windmill-street were acquired from a Mr. Goodge at a yearly rental of £30, the institution being christened the "Middlesex Infirmary." A year later the name was changed to "The Middlesex Hospital," and it was further decided that its government should be vested in annual subscribers of £3 3*s*., to be called "governors," which qualification obtains to the present day. It was also ordered that no pupil or apprentice should be permitted to attend the practice in the hospital without the permission and approbation of the weekly board. Accordingly, Mr. Hamilton, one of the surgeons, presented Lucas Everard Greenhead as his apprentice, who consequently became the first Middlesex student; and later, when the number of dressers, as they were now termed, increased, rules were drawn up for their behaviour, among which we find that they were not to stay in the hospital after they had finished their work, were not to swear, make noises, or embezzle the medicine.

Soon after the infirmary was started some of the lay officials got into trouble owing to its exposed position. The matron was strictly enjoined to lock the door at 11 P.M., and later was dismissed because, with the messenger, she had not acquainted the committee of several irregularities committed by others to the great disrepute of the hospital. The apothecary is stated to have "committed actions vile and enormous," the behaviour of the patients became so bad that it was proposed to give the steward the power of suspending their diet as a punishment, and the following regulations were made: "That no patient should talk to anyone in the street. That patients should not presume to talk to one another after 9 P.M. That liquors should not be brought into the hospital without leave of the steward." The number of beds when the building was first acquired is not mentioned, but they soon became very overcrowded, and as apparently two patients had sometimes been put into one bed rules were drawn up limiting the number of in-patients to the number of beds. In 1747 it was decided that 15 beds should be the standard for the future, that five of these should be reserved for lying-in cases, and that Dr. Layard should be appointed man-midwife in ordinary. One pound of pins and two pincushions were ordered for the department and a nurse hired at a salary of £8 a year.

FIRST LYING-IN HOSPITAL IN ENGLAND.

This reservation of beds for maternity cases is very interesting, inasmuch as by it the Middlesex Hospital became the first lying-in hospital in England, and, further, this department became so popular that it was both at the same time nearly the means of ruining the old hospital and also the means of getting the present one built. Apparently the weekly board must have thought the obstetric officers of those times a grasping lot, since they were very careful when apportioning the five beds to make the following minute which states that "as it was apprehended that the novelty of the scheme might in future tempt the governors of that part of the charity to endeavour to convert the whole hospital to the use of that branch only, it was agreed that a third part of the beds and no more should be applied for that purpose, leaving for the sick and lame a third part each," which agreement was then thought so equal and just that the obstetric physician declared his entire approbation and gave his honour he would never attempt in anywise to injure that part of the charity devoted to the sick and lame, nor deviate from this equal proportion then agreed to. But, alas for the frailty of human nature, two years later the obstetric physician, backed by the senior physician and abetted by the chaplain, plotted to convert the hospital into one for maternity cases only. On the plot being discovered the two physicians resigned, as also did the president, whilst the secretary, matron, steward, and messenger were discharged. Nevertheless, so anxious was the weekly board to please everyone it increased the number of beds from 18 to 24, and set aside 10 for the maternity cases. Even this, however, did not satisfy the late senior physician, who set to work to try to ruin the hospital, as did also the treasurer, who refused to receive subscriptions or account for those he had till his successor was appointed. It was then resolved that half the beds in the hospital should be reserved for maternity cases, which the late obstetric physician thought so reasonable that he agreed to rejoin the staff, giving his word of honour to be satisfied. However, a fortnight later something again seems to have upset him and he resigned for good.

INCEPTION OF PRESENT BUILDING.

The additional beds being insufficient to cope with the number of maternity cases, a room had often to be hired in the neighbourhood and so it was decided that a new hospital must be built. Our present building, therefore, really owes its inception to the popularity of the obstetric officers, maternity nurses, and the lying-in department of 159 years ago. The weekly board was also very anxious for a

new hospital as it badly wanted a board room, its meetings up to then having been held in the "Bear and Rummer," a tavern still standing almost opposite the hospital. In 1754 a piece of ground in the Marylebone Fields was acquired from Mr. Berners for a term of 999 years at the rent of 2*s.* for every foot in front of the said ground.

The piece of land in question whereon this afternoon we are gathered was quite on the outskirts of the town, and was a favourite place for snipe shooting, being separated from Tottenham Court-road by ponds and marshy lands, whilst just to the north of it was the "Farthing Pie House," the last place of refreshment for travellers before they disappeared into the country, and later replaced by the "Green Man," still standing opposite Portland-road Station, which now supplies refreshment for travellers before they disappear into the "Tube."

On June 15th, 1755, the foundation-stone was laid by the Earl of Northumberland, assisted by the vice-presidents and governors, who, after having attended the anniversary service at St. Ann's Church, walked by way of Dean-street across Oxford-street and up Newman-street to the Marylebone Fields for that purpose. A Mr. Gray had contracted to build the hospital for £2250, and during the next year or so the building committee was very hard pressed to find the necessary money. The theatrical profession came to the rescue, as it has done on so many occasions since, and David Garrick gave the receipts of two performances, choosing on the last occasion *Much Ado About Nothing* as being a favourite play with the ladies. At last in 1757 64 beds were ready for the reception of patients. The hospital is described as being a "neat, plain, and not inelegant red brick building having the decent appearance and all the accommodation one could wish in a house devoted to charity without that ostentatious magnificence which too often in a great measure defeats the humane and noble end of such pious and charitable institutions where those sums are squandered in useless decorations that ought to be employed in administering health to the sick and giving feet to the lame." Our hospital was first of all built without the present wings and was not quite so complete as the descriptions of it would have us believe, since an operating theatre had not been included. This omission was rectified four years later and one provided on the top storey.

EVENTS IN THE EARLY HISTORY OF THE HOSPITAL.

In 1757 the office of house surgeon was created, the first gentleman to hold that post being Joseph Barker. In 1762, the hospital being in a flourishing condition, it was decided to take steps for building the west wing. At this time also the weekly board made a bargain with a gentleman named Legrand, 74 years of age, wherein for a legacy of £600 it agreed to let him reside in the hospital and to provide him "with all necessaries during the time of his natural life," a questionable bargain since he lived for eight years.

In 1763, owing to the number of maternity patients, the obstetric officers decided to attend some of those women in their own homes. In 1770 the west wing was finished but only the ground floor opened. In 1774 the students of the hospital formed themselves into a medical society and asked for the use of the physician's room for their meetings. The board unanimously agreed to the proposal "provided that the society would be at the expense of their own candles." Thus arose the oldest medical society in England, which at the present day flourishes more vigorously than ever, meets in the same room, and the governors kindly pay for the electric light.

In 1777 the treasurer was directed to obtain an estimate for laying out the waste ground at the back of the hospital "either as a garden for pot-herbs, for a drying ground, or for walks for the patients to whose health such air may be conducive." Three years later the ground was ploughed and cropped with potatoes and French beans, but after five years the board gave up market-gardening as hopeless, and in 1785 poplars were planted and grass-plots sown, the collector of the hospital undertaking for the sum of £5 and the hay to look after the garden.

In 1780 the east wing was completed but remained empty for want of funds. Three years later, the finances of the hospital being still depressed, some additional wards were closed and the maternity beds were reduced from 34 to six, and they were further reduced in 1786 to two for similar reasons. In this year also midwives were appointed to attend patients in their own homes under the supervision of the obstetric physician, he being granted the sum of 5*s.* per case to defray the charge of midwife, coach hire, and other individual expenses. The same custom has obtained up to recently except that the physician did not get the 5*s.*

In 1789 Howard, the philanthropist, was constrained to severely criticise the weekly board for keeping the hospital so dirty. The board thought fit to reply in a circular which stated that the criticism was most unjust and "that they would be much honoured by another visit from Mr. Howard, who, they flatter themselves, will in a future publication expiate his ill-impression by a true description." Erasmus Wilson remarks that in anticipation of such a visit, conjoined possibly with the still small voice of conscience, great activity followed this circular, and quite sufficient was ordered to be done to prove that Mr. Howard's strictures were not without foundation.

In 1790 the wards for the male and female patients were arranged on opposite sides of the hospital, a custom that has just been changed by the inauguration of the "linked-ward system."

In 1792 the Cancer Charity, an institution of much importance in relation with the Middlesex Hospital, was founded in this wise. Mr. Howard, a surgeon of Argyll-street, appeared at the board and informed the governors that a friend wished to contribute £3000 towards establishing a fund to endow a ward for the reception of persons afflicted with this disorder. The offer was gratefully accepted, and on the death of the founder it transpired that he was Samuel Whitbread.

In 1793 a ward was set apart for the reception of French clergy driven into exile by the Revolution. Each inmate had to contribute 8*s.* a week exclusive of burial fees, nurses' wages, and bedding, which were to be provided by a relief committee. The refugees occupied the ward 14 years and on leaving gave their bedding and mattresses to the hospital as a thankoffering.

In 1796 that most important part of a hospital, the medical school, was first mooted and wards were allocated for a chemical laboratory and lecture theatre.

In 1800 our hospital was suffering severely from the effects of the war, and, owing to the great scarcity of every article of life, the treasurer requested the gentlemen of the board room table to abstain from their allowance of fresh butter, and the nurses and servants were each limited to half a pound of butter and one pound of cheese per week. The allowance of bread was also reduced to one quartern loaf in seven days for everyone in the hospital as being in strict conformity with the commands of His Majesty to his subjects in general, and linseed meal was substituted for bread in the poultices, but as the meat was often bad, the beer undrinkable, and potatoes scarce, the servants struck, and were consequently given in addition a small allowance of rice. In 1807, with a view to further economies, the remaining maternity beds were abolished.

In 1809 the board came to the conclusion that an annual dinner would conduce to the interests of the hospital, and, for all I know to the contrary, the dinner to-night will be the 104th consecutive one of its kind.

In 1812 the Samaritan Fund was proposed by Mr. Cartwright, one of the surgeons, its object being to afford temporary assistance to poor convalescent patients, to forward patients, especially cripples, to their homes, and to supply flannel, linen, and other necessaries.

In 1815 there were 179 beds in the hospital, and that the management and treatment were the best of their kind at this time is evidenced from an anonymous donation of £10 to the funds of the hospital by one who had read a review of a French traveller's tour in Great Britain as follows: "The traveller is now taken to one of the public hospitals of which he gives no very favourable account. We fear that his statement as far as it relates to one or two of these receptacles for human misery is but too true ..... but could we indeed have carried our traveller to the Middlesex Hospital he would have witnessed that benevolence of manner and that delicacy of attention exercised by all the medical attendants even to the poorest of their patients which imparts a charm to the powers of medicine and disarms sickness itself of half its anguish. The poor have feelings in disease no less than the rich, fortunately indeed for them not so tremblingly fastidious, but sufficiently acute to animate the exertions of humanity and to repress the

insolence of vulgar brutality." And what was true of the Middlesex Hospital nearly 100 years ago is, I hope, trust, and believe, true of the Middlesex Hospital to-day, and as an indication of its popularity with patients, I find in the report of King Edward's Fund, just issued, that whereas the average daily number of unoccupied beds in the 16 largest hospitals in London was 12 per cent, the average number at Middlesex was only 4·7 per cent.; and further, we have always a long waiting list, so that on one historical day this summer there were over 250 patients waiting for admission, and what perhaps was more striking still, was that the vast bulk of these patients seemed to be clamouring for operative treatment, a compliment to both our surgeons and physicians—to the surgeons for obvious reasons, to the physicians as showing that they cured the medical patients so quickly there were hardly any waiting for admission.

In 1821 the weekly board, ever ready as far as they could to prevent waste and extravagance, appointed a committee to inquire into the hospital expenditure, which reported that the consumption of drugs had increased very much because the surgeons had taken to ordering their patients medicine, and that the cost of the medicine had also increased because the physicians were fond of trying new and expensive drugs which the board did not think should be given to patients in a charitable institution. I have heard such criticism even in the twentieth century. The apothecary also had been reckless with the leeches, doling them out at about the rate of a hundred a day, so that during the year under discussion he had bought 36,100 of this annelida. The board rightly viewed such extravagance with much disfavour and ordered that, in the future, after the leeches had been used, they should be properly preserved for further applications. The amount of wine consumed seemed to puzzle the committee, which could only refer the matter to the medical gentlemen for an explanation. As the late matron had given the extra nurses meat in lieu of their wages and had doubled its supply to the regular nurses, the committee was not surprised that the amount of this commodity had likewise increased.

In 1824 several other wards were opened and the total number of beds increased to 200.

In 1828 London University, now known as University College, was established in Gower-street; thereupon, and during this year and the next, repeated overtures were made to the governors of the Middlesex Hospital for amalgamation, and, as our board was then in need of funds, the University offered to subscribe £3000. The governors, however, would have none of it, first of all, because the founders of the University had advertised in the *Times* suggesting that Middlesex Hospital was affiliated to it; and, secondly, the governors thought that if they joined an unsectarian university they would lose a large number of subscribers. In 1834 the wings of the hospital were extended some 30 feet, thus increasing the number of beds to 240.

INSTITUTION OF THE MEDICAL SCHOOL.

1835 may be regarded as the second most important date in the history of the Middlesex Hospital, the chairman at the annual dinner announcing that it had been decided to build a medical school on the ground belonging to the hospital. The staff had pointed out that until the celebrated school of medicine in Windmill-street had been eclipsed by London University building its own hospital there had been no lack of pupils, but that now the number of pupils had seriously decreased, "that hospitals by furnishing the means and materials of medical education were capable of yielding indirect and incidental advantages to the public far outweighing in extent and importance the personal benefits they offer to the direct objects of their charity," and that "through the hundreds of young men who were taught in the hospitals the great consolation to be derived from judicious medical and surgical aid is afterwards extended to thousands in all parts of the country and in every rank of society. It is not, perhaps, sufficiently recognised that the judgment and skill to which every man in periods of sickness and danger is glad to confide his life and the lives of those most dear to him have been acquired in the first instance in the wards of a hospital." Further, a medical school attached to a hospital is of the greatest advantage to the patients themselves, since "it surrounds the medical staff with a crowd of watchful, inquiring, and often very highly intelligent observers who expect an explanation of the various diseases they witness and a reason for the treatment applied to them"; and yet with full knowledge of all this we have recently had ill-advised, though doubtless well-meaning, people advocating successfully that the medical schools must not receive financial aid of any kind from the hospitals.

FURTHER DEVELOPMENTS.

In 1838 the operating-theatre was transferred to its present position, the space thus left vacant being converted into a ward now known as "King's Ward." Another indication of the debt we owe to the obstetric side of this hospital is instanced in the foundation of our museum, the nucleus of which consisted of specimens, some 660 in number, collected by the then obstetric physician and acquired after his death in 1839. In 1840 the porch of the hospital was built at a cost of £100, and four years later the out-patient department was enlarged by advancing the ground floor of the east wing to the railings.

In 1843 a charter of incorporation was granted to the hospital through the exertions of Mr. William Tooke, M.P., the honorary solicitor to the hospital, thus once and for all surmounting a very serious disadvantage the hospital had experienced on several occasions. In this year, also, the office of surgeon-dentist was created and Sir John Tomes was elected to the post, so that the Middlesex Hospital started the first dental department in London, which formed the chief place for study in this branch of medicine until the dental hospitals were founded.

In 1848 the accommodation in the hospital was increased by 55 beds, fireproof staircases were substituted for those already in the building, and a laundry was built underneath Bird ward.

In 1855 the Middlesex Club was founded by Dr. Tom Taylor to assist old Middlesex men, 50 members joining. The members have met every year since, and at its jubilee dinner the chair was taken by one of the founders, Mr. Thomas Nunn, who died three years ago, mourned by every Middlesex man who had had the privilege of his acquaintance. The club is the oldest of its kind in London, and its great success is due to the untiring efforts of Mr. Andrew Clark, honorary surgeon to the King, who has been treasurer for the last 29 years.

In 1856 the office of dean was created, the first occupant of the post being Dr. Temple Frere.

During the few years prior to 1869 the nursing department had come under the notice of the board, with the result that it was improved and reorganised, and part of the improvements consisted in the building of a nurses' home in Cleveland-street, which was opened by Her Royal Highness Princess Mary of Teck. At this time Miss Thorold was appointed lady superintendent of nurses, and for the next 36 years she devoted her life to the benefit of the patients and to the advancement of the nursing profession. The nursing home was extended in 1878 and again in 1904, when the block of buildings adjoining the residential college was opened.

In 1875 an additional storey was added to the Medical School, which up to then had remained in the same state as when it was first erected. Five years later a new lecture theatre was built and the dissecting room enlarged. In 1884 extensive alterations were made in the out-patient department, the opening ceremony being performed by Her Royal Highness the Princess Christian of Schleswig-Holstein.

In 1887 the school buildings underwent a remarkable extension, the present block, together with a residential college, being erected on the east side of the garden. In 1890, owing to the generosity of Miss Leicester, our chapel was built, and thus was fulfilled an object very dear to the heart of the late Mr. George Lawson, who in 1882 had initiated the idea with a promise to build the chapel could a site be found. Owing, however, to the expense of rebuilding elsewhere the laboratories, situated upon the only site available, the matter had hung fire till Miss Leicester's offer enabled Mr. Lawson and others to devote the money they had promised for the chapel to the laboratories. The internal decorations were mostly defrayed by the Ross Memorial Fund; by the late Kenneth Lawson, a former house physician, son of Mr. George Lawson, who left the munificent sum of £500 for that purpose, and by Mr. Bland-Sutton. The Princess May Wards for Children, which we owe to the loyalty of an old student, were opened in

1892 by Her Royal Highness the Duchess of York, now our most gracious Queen.

A convalescent home was first contemplated by the weekly board in 1877, but, owing to lack of funds, the matter had been allowed to drag on without any active steps being taken. In 1891, however, an offer of £500 from Mr. Frank Debenham, a member of the weekly board, towards the erection of the home, stimulated the authorities to greater exertions, and in 1893 the site at Clacton was purchased. Before the completion of the building in 1896 a munificent legacy by Mr. Harry Spicer allayed all anxiety as to how the expenses of upkeep were to be met. The value of this home to the patients and hospital cannot be over-estimated, for not only has it greatly assisted in restoring to health large numbers of men, women, and children, many of whom had never before experienced the benefit of sea air, but also by receiving patients at an earlier date than that on which they can be sent home, it has increased the number of beds available for serious cases in the hospital, and thereby is of the greatest assistance to the poor in our immediate neighbourhood.

In 1895 the operating theatre was rebuilt and the opportunity was taken to augment this department by erecting an additional theatre, sterilising room, anæsthetic room, and rooms for the surgeons and nurses.

In January, 1900, the female cancer patients were removed to the new wing in Nassau-street, a building with accommodation for 36 patients, nurses, and research laboratories. The ground had been acquired from Mr. C. H. Berners, a descendant of the lessor of the original site to the hospital, and the money for the building had been collected during the previous six years, his late Majesty, King Edward VII., when Prince of Wales, having with his usual generosity presided at a dinner in 1894 at which was collected over £9000, £1000 of this sum being contributed by Mr. Samuel Whitbread, M.P., great grandson of the founder of the charity.

In 1901 the laundry was removed to Hendon and the kitchen to the top of the hospital, an improvement which gave much satisfaction to the medical staff since the kitchen was situated under the board room and to the patients in Bird ward since the laundry was underneath them; for the odours connected with washing and cooking, though appropriate enough in their own surroundings, seemed to be out of place in a sick ward and in a room where grave debates were of daily occurrence. At the same time the opportunity was taken of extending the East Wing towards the north, so that Helena and Seymour Wards were enlarged, and the Gynæcological department was remodelled and provided with an operating theatre.

In 1904 Mr. Edmund Dresden left us £32,000, the income to be employed in assisting poor and needy in-patients on their discharge from the hospital.

The year 1905 was a very anxious one for our medical school, the hospital authorities having been forced to withdraw from it all financial aid owing to the action of King Edward's Fund, which intimated that it would not make grants to a hospital which used any part of its general funds towards its school expenses; and it looked at one time as if our school would be ruined, but chiefly owing to the strenuous advocacy of Sir Henry Morris, who also gave £1000 to form the nucleus of an endowment fund, it was saved.

In 1908 part of the fourth storey of the east wing was remodelled, and in the place of two small wards and some bedrooms a maternity department was built consisting of two wards, the usual offices, a theatre, and a baby-washing room. The cost of this attractive addition to the hospital was borne by the Annie Zunz trustees, and for the suggestion of again admitting maternity patients we are indebted to Sir James Kingston Fowler, who forcibly impressed upon the board the great advantage to our hospital and school in so doing. Since these wards have been opened a number of our own nurses have been trained for the State examination of the Central Midwives Board and not a single one has failed.

The next year the trustees of the Barnato bequest, a memorial to the late Mr. Barney Barnato and Mr. Woolf Joel, elected to establish the Barnato-Joel Charity in connexion with our cancer department. For this purpose a magnificent building, containing every modern convenience for the well-being and comfort of the patients, is being erected adjacent to our own cancer wing for the reception of 43 in-patients. The building includes an out-patient department, a nurses' home, spacious laboratories for the investigation of cancer, and an electrical and radium institute. Under the authority given to them the trustees have delegated the actual management of their charity to the weekly board. This splendid addition to the cancer department is the most memorable event in its history since its foundation. It must be remembered that the funds of the Barnato-Joel Charity and our own cancer charity are kept quite separate from those of the hospital and have nothing to do with it.

Thirty-three years ago one might have seen a pale, thin, and serious-looking lad with ambition stamped on every feature spending most of the day perambulating between St. Mary's Hospital and our own. His coat was tightly buttoned, one hand clasped over his breast pocket, and he seemed to be undecided, but at last his mind was made up, and on arriving once more at the Middlesex Hospital he entered its portals and asked to see the Dean. After a searching cross-examination as to the advantages to be gained by joining the school, and as to the lowest terms upon which it was possible to join it, approval was signified, the lad became a "Middlesex man," and paid on the spot for the privilege in coin of the realm which he carefully counted out of a bag to the amount of £90. In October, 1909, one might have seen enter the secretary's office a man whose appearance was mellowed by time. He had drunk deep in the waters of success; ambition was satisfied. Drawing from his pocket £1000 in cash he now asked the assistant secretary to count it. This was the erstwhile lad's thankoffering for being a "Middlesex man," and thus to John Bland-Sutton we owe our recreation-ground, the want of which had been felt for so many years and the absence of which had deterred so many students from joining the hospital.

In 1910 an application was made to the weekly board by one of our students to provide an asylum for some refugees from the Zoological Gardens. The board, with the precedent of the Medical Society before it, agreed to allocate the hospital garden to six squirrels, "provided Mr. Poynder would be at the expense of the nuts." The squirrels, which are quite tame and afford great amusement to the patients, have been accompanied the last few days by others several sizes smaller than themselves.

The latest change I have to notice is that known as the "linked-ward system." The weekly board in its praiseworthy endeavour to decrease the hospital expenditure has been satisfied that by having the male and female wards of each officer adjacent instead of on opposite sides of the building, the cost of upkeep will be materially decreased. It therefore directed the medical staff to make this change. Remembering the part the obstetric department has played in the history of our hospital it is interesting to note that this change could not have been affected without the consent of the obstetric surgeon or his resignation, since this scheme is both destructive and constructive, for to give the physicians and surgeons linked-wards, the only perfect link in the hospital, the obstetric and gynæcological department has been rent in twain and destroyed for ever, and I trust at the quincentenary introductory address of our medical school the future lecturer will remember that this great change was brought about by the self-abnegation of the obstetric officers.

This, then, is a brief outline of what has happened to our hospital since its foundation, and now a few words about some of the men who have enabled all this to be accomplished.

THE LATE PRINCE FRANCIS OF TECK.

The most important member of our hospital is the chairman of the weekly board, and just before I joined Major Ross, the best chairman the hospital had ever possessed and who had occupied that position for 21 years, died. Since then the fortunes of the hospital have been ably guided by Lord Sandhurst and Lord Cheylesmore among others, and in the late Prince Francis of Teck the hospital had in many ways the greatest chairman of them all. His attributes were such that, had he been born in any other walk of life, he must have risen to great distinction and a very high position. His late Serene Highness was versatile to a degree, a soldier who had served his country faithfully and well in India, Egypt, and South Africa, a keen sportsman, a first-rate man of business, possessed of great common sense, and of a large-hearted sympathy with those in distress. He

gave of his best for the welfare of this hospital, an object which I know was dearer to his heart than any other. Those of us who had the privilege of his acquaintance were always struck by his cheerfulness, great courtesy, his mastery of all the details of hospital management, his personal interest in every department, the accuracy of his judgment, and the soundness of his advice, which was always at the disposal of any who liked to ask for it. To Prince Francis we owe the provision of the maternity department, the conception of the scheme for linking the Barnato-Joel Memorial with our cancer charity, and the liquidation of the debt of £20,000 which was due to our bankers when he became chairman. In connexion with his grasp of detail and business capacity Mr. Joel told us at the laying of the foundation-stone of the Barnato-Joel memorial that the trustees had had many schemes put before them for their consideration, but that the proposition of Prince Francis was so business-like they had no hesitation then and there in acceding to his wishes.

The late Prince, if he undertook to do anything, did it with all his might; half measures were foreign to his nature; playing with charity was his abhorrence. It therefore came about that when he offered to clear off the hospital debt he set to work in such a determined way that in three months he had accomplished this great and self-imposed task. What it meant to him and how hard he worked few will ever know. He spent days and weeks at this hospital, signing, writing, dictating letters, and interviewing people in all grades of society, from the old flower-woman who gave him 5*s*. to the noble lord who gave him £500, and not only did he work whilst at the hospital, but also when away from it, at his home, when visiting, anywhere in fact, and he told me that he was never satisfied unless he wrote 30 letters each week-end. For those working at the hospital his presence was a source of never-ending stimulation and encouragement; it was impossible not to try to do one's best with such a man at the helm. Everyone knew they had only to perform their duties efficiently to have his support through thick and thin.

Perhaps the Prince's greatest attribute was his sympathy with the poorer classes. If he could in any way alleviate their lot he did so, and I often think that this was the reason why he took up hospital work. He knew what illness means so often in the homes of the poor—absence of suitable and perhaps sufficient food, of proper medical attendance, of good nursing, of comfort, and of all that goes to lessen a little the awful misery of illness. He knew that in a well-managed hospital the poor are on the same plane as the rich, everything that science and knowledge can bring to their aid being at their disposal, together with efficient nursing and good food. He realised that to increase the scope and efficiency of the hospitals was to lessen the misery and to lighten the sorrows of the poor, and had he lived he would undoubtedly have become our greatest authority on hospital management and work. Genial, popular, and kind, his late Serene Highness will ever be remembered by us all with esteem and gratitude as "the poor man's friend."

The first President was the second Duke of Portland, who after a short term of office retired owing to the trouble in the obstetrical department. He was succeeded by Hugh, Earl (afterwards Duke) of Northumberland, and since then this office has been filled by the duke's descendants to the great good of the hospital, which is indebted to them for much generosity and willing assistance.

THE MEDICAL STAFF.

Of the medical staff time does not permit me to say much. The Middlesex Hospital during the 166 years of its existence has been fortunate in counting among its physicians and surgeons some of the most noted men of their day. Among the physicians were Charles Morton, who became principal librarian of the British Museum; Henry Hinckley, for 17 years treasurer of the Royal College of Physicians; Richard Warren, physician to George III.; Hugh Smith, who was also a City alderman and wrote a treatise appropriately enough on "blood letting"; Sir Lucas Pepys, the first Middlesex physician to attain the dignity of President of the Royal College of Physicians and the honour of a baronetcy; Sir Francis Milman, President of the Royal College of Physicians; John Latham, President of the Royal College of Physicians and physician to George IV., who in 1791 published a pamphlet entitled "A Plan of a Charitable Institution to be Established on the Sea Coast," thus anticipating the convalescent home at Clacton; Sir Henry Halford, physician to four Sovereigns, and for 24 years President of the Royal College of Physicians; Sir Thomas Watson, born in 1792. His published lectures, the result of 17 years' work at our hospital, are unique in their lucidity, accuracy, and originality, and have been compared to the works of Sydenham; whilst so scholarly was his style that he was known, according to a presidential address in the Transactions of the Royal Medical and Chirurgical Society, as the Cicero of English medical literature. He was five years President of the Royal College of Physicians, and died at the age of 91. His son, Sir Arthur Watson, was vice-chairman of the weekly board for some years. Henry Southey, brother of the Poet Laureate; Francis Hawkins, physician to the household of William IV. and Queen Victoria and 29 years registrar of the Royal College of Physicians; Sir John Burdon Sanderson, later Regius professor of medicine at Oxford; William Cayley, a physician beloved by all and who served the hospital with unswerving devotion for 35 years; and Sir Richard Douglas-Powell, physician to three Sovereigns and for five years President of the Royal College of Physicians, both the latter, though retired from the staff, are happily still with us.

Of the surgeons in the early years of the hospital's existence but few particulars are available. Later, and most noted of our surgeons, was Sir Charles Bell, for ten years a colleague of Sir Thomas Watson, so that for a decade there worked together as physician and surgeon at this hospital two of the brightest ornaments we have ever had. He was elected to the staff in 1814 and was the founder of our medical school. In a brilliant character sketch Stephen Paget describes him as having "all the gifts of the gods; he was versatile, emotional, practical, urbane, a lover of music, touched by every sight and every sound in the streets, now exalted, now depressed, and enraptured alike by solitude and by a crowd." In a letter to his brother concerning his election to the staff Bell writes: "They say I have had the wit to win over Whitbread or to bribe him, that I have bribed all the medical men of the hospital, that I am an anatomist, that I have a large class, and therefore the hospital has taken me up. The medical men of the hospital say they have lived as a family and expect me to be a loving brother of the community;" and in a later letter describing his success by a majority of 265 votes he remarks that the senior physician, Dr. Gower, was so pleased with the result that he was discovered, thinking himself unobserved, "dancing a reel in the board room." Bell, one of the greatest surgeons and physiologists England ever had, resigned after 24 years' devoted service to become professor of surgery at the University of Edinburgh. He was succeeded by his brother-in-law, Alexander Shaw. Following these we have had:—Moncrieff Arnot, twice President of the Royal College of Surgeons, a very plain-spoken but kind-hearted man, who on one day visiting his wards was stopped by a patient with a fractured leg, saying, "Oh, Mr. Arnott, I have such a sinking in the stomach." "Now, my man," said Arnott, quickly discounting the alleged symptom, "why don't you say you want another pint of beer?" Campbell de Morgan, a pioneer in antiseptics and a great advocate for the thorough removal of cancer. Sir William Flower, Director of the Natural History Museum. John Whittaker Hulke, F.R.S., who died in the second year of his Presidency of the Royal College of Surgeons from pneumonia acquired through coming to the hospital on a snowy winter's night to perform an urgent operation which a sense of duty forbade him give to his junior. George Lawson, oculist to Queen Victoria, who worked 22 years at this hospital attending to the surgical ailments of the patients and relieving their physical necessities; his life was one long record of unostentatious benevolence. Charles Leopold Hudson, one of the most brilliant students the hospital ever had, and at the time of his deplorable death assistant surgeon. He started the Students' *Journal*, and was responsible for the amalgamation of the sporting clubs, which has met with the great success he always prophesied. And Sir Henry Morris, now retired from active work on the staff, thrice President of the Royal College of Surgeons of England, and who, quite apart from all else he has done for the profession and humanity, will be remembered always as the first surgeon to perform the operation of nephrotomy.

Of resident medical officers there have been many. They were at first called apothecaries, and our hospital has a lot

to thank them for. The most noted of them was Edward Ashby Fardon, who spent the whole of his medical career in this hospital, and was for 28 years its resident medical officer, during which time he was intimately associated with all the reforms and improvements then carried out, many of which he initiated. The welfare of our hospital was his first object in life, and he died in its service.

THE POST OF SECRETARY.

Of the secretaries to the hospital history relates but little. Some of them left because they were married, some were discharged because they were not, some resigned because they were clergymen, others had to resign because they were not clergymen, for at one time the offices of chaplain and secretary-superintendent were combined; some retired from ill-health, some were expelled for plotting against the authorities, one was dismissed for late habits and a propensity for erasing his name from the night-book, another was arrested on the hospital premises, a third when dealing with the hospital accounts had such very elementary ideas of *meum* and *tuum* that he left to improve his education, and a fourth opined that "his habits were not such as the governors would deem suitable in the situation of secretary." Whether in the main they were happy or unhappy we know not, but at any rate there was one discontented with his lot, for on being asked what he would sooner be if his wish could be gratified replied "a golden carp swimming about in a lake of the finest champagne with the beautiful fluid running in at my mouth and out of my gills every second of my life." Of former secretary-superintendents, Alexander Shedder did by far the most for the hospital, working here for 24 years.

Up to now, in dealing with the people who have helped to make this hospital, I have for obvious reasons mostly mentioned those who are dead or who have retired, but it is impossible thus to pass over the present secretary-superintendent. He entered the hospital on Jan. 1st, 1878, as a clerk, and for the last 33 years one might truly say that every day of his life he has been working in some way or other for its welfare. There has been no eight hours' day for him. As a house surgeon 20 years ago I have often, when going to the wards for some urgent case at 12 or 1 o'clock in the morning, seen the office lights burning and the secretary in his shirt sleeves surrounded by huge ledgers. This year, called to the hospital at 1 A.M. on a similar errand, I have seen the office lights still burning and the secretary still working in his endeavour to collect funds for the hospital, and I was informed that this had been a nightly occurrence for months.

The functions of a secretary-superintendent are manifold, the two principal being, perhaps, the collection of funds and the limiting of expenses. During the present secretary's term of office close upon one million pounds sterling have been spent on relieving the patients, keeping the hospital fabric in repair, and extending its buildings. That takes some collecting! And in the report of the King Edward's Fund for 1909 the average cost per bed at the Middlesex Hospital was the lowest of any of the great hospitals, whilst in the report for 1910 results almost as good have been obtained, and our average cost per bed is stated to be over £7 less than in a hospital more than twice our size which has all the advantages in buying an increased number of beds necessarily gives; this takes some managing! No one deserves more of Middlesex—nay, of the community—than F. Clare Melhado, whose monument is already erected in the large number of buildings that surround this garden.

INADEQUACY OF THE OUT-PATIENT DEPARTMENT.

Every year at our annual dinner the Broderip scholar, the most learned of our students, when returning thanks on their behalf, will ventilate a list of grievances. This custom has always appeared to me to have much to recommend it. Private representations are notoriously often of very little use, since the request is either met with a direct negative or is received with the honeyed phrases of apparent sympathy only to be forthwith relegated to the dust and limber of the forgotten. On the other hand, publicity will often work wonders, and I have known many a useful suggestion thrown out by a Broderip scholar bear fruit, not perhaps at once, but after the authorities have allowed the matter to undergo unconscious cerebration. It has occurred to me that this custom of the Broderip scholars might very well be followed by the lecturer of the day who is not likely to often have such a chance again of ventilating any grievance he may have personally or on behalf of his colleagues. There will be some members of this audience saying to themselves, "I wonder what grievances the medical staff of the Middlesex Hospital can possibly have." Well, ladies and gentlemen, I must not let you into all the secrets, but, at any rate, we have one grievance, and that a most pressing one, which is the entirely inadequate accommodation available in the out-patient department. This hospital may now be said to be practically complete and up to date except for this. The time has come when we must have a new out-patient department, both for the sake of our patients and for that of our colleagues who have to spend so many hours there every day. Go round to the surgery, the consulting-rooms, corridors, and waiting-rooms this afternoon and see for yourselves; the sister-in-charge will gladly show you. Then imagine that, on an average, at least 500 patients, and on Tuesdays very often 700, are examined and treated every day, that all the serious accidents are first brought there, that all patients for admission have to be seen there first, and that the dispensing for the whole hospital is done there. You will deem it impossible in such a small and cramped space; in fact, there is hardly room to breathe, and it would be impossible if it was not for the loyalty of the staff working under such surroundings and for the fact that the patients are so attracted by the popularity of the hospital that they are prepared to put up with an amount of inconvenience which, under other circumstances, they would not tolerate for a moment. As the sister-in-charge said to me recently, "It's bad enough any day, but on Tuesdays it's something awful." The room set aside for dental work is somewhat larger than a rabbit hutch, and in a short time, in spite of every means taken to ventilate it, the air becomes so vitiated that the dental surgeon tells me he invariably feels ill for the rest of the day after he has finished his work there, and every now and again he loses the services of the nurse on duty from fainting. Working in the out-patient department is not a healthy occupation anyhow; many a man has ruined his health, many a man has lost his life working there. I wonder how many of you have any idea as to what a man has to do before he becomes a physician or surgeon to out-patients. Let me lift the veil a little, you shall perceive a mode of life that is not riotously healthy.

You will see a young man working, always working at the hospital most of the day, and at home or in lodgings up to late at night, with but scant holidays for at least five years, in order to take a high place in his qualifying examination. You will then see him filling the various resident posts that a hospital has to offer, unsalaried posts. Later on you will see him working for one of the higher diplomas, without which he is not eligible for a position on the staff. During this time he has to pay for his board and lodging. Having passed this most difficult examination, you will see him, perhaps, as registrar, a position which necessitates his presence at the hospital six days of the week, which entails a great amount of work, and which is in every way a very exacting occupation. The salary for this varies; at our hospital it is £40 and a free lunch. Roughly, therefore, after about eight years of very hard work, our prospective candidate commences to earn £40 a year. His work is of such a nature that it is impossible for him to earn a living at private practice; he therefore has to look about for some other means of subsistence, such as that of "coaching" students for their examinations, and what work that entails none but a "coach" will ever know. I had 12 years of it, and it is certainly the hardest job that I can imagine, working day after day often up to the early hours of the morning endeavouring to get a small number of men to assimilate a large amount of knowledge, realising all the while full well that whether you obtain any more students depends entirely upon how the present ones prosper in their examination. The time at last arrives when there is a vacancy on the staff; there are sure to be a large number of candidates; only one is chosen, and perhaps it is not the registrar, but we will say it is. His expenses suddenly rise to an alarming degree, he has to take rooms or a house in some particular neighbourhood with the knowledge that, unless he differs in a marked degree from those who have gone before him, he will have to work hard, day in day out, probably without proper holidays, for at least seven years more before his receipts will be equal to his expenditure—that is to say, if he has passed his examinations and obtained the various posts at the first time

of asking, in about 18 or 19 years after he is qualified our friend may be earning enough to pay his house-rent and expenses. Is there any other walk of life in which *such* work is remunerated so inadequately as this? I think not. And then you must remember that with all this hard work there is the anxiety to some of the uncertainty as to whether the next butcher's bill can be paid or not. What with working in the out-patient department day after day for many years, teaching and lecturing to the students, writing papers for learned societies, perhaps undertaking research work, and many other duties associated with his position, no wonder the health at times gives way under the strain. Those who have to work year after year in our out-patient department incur over and above the ordinary risk to their health a definite risk due entirely to the size and nature of the building. This is no fancy, it is a solemn fact. Our present department did very well for the time it was built in 1886, when the yearly number of patients was comparatively small. To-day it is absolutely inadequate with yearly attendances of 141,529. A new out-patient department would mean greater comfort and privacy to the patients and less waiting, and time to many of them is money indeed. The work could be more efficiently carried out, the students would have better opportunities for learning, and it would be incalculably better for the health of everyone concerned.

If I were delivering this address in New York or Chicago I should have in all probability to-morrow morning an offer from some public-spirited millionaire to build the Middlesex Hospital a new out-patient department. Cannot I persuade someone in England to do this for us? I cannot imagine a finer memorial to anyone—a memorial that would not only benefit the patients, but also would be of inestimable advantage to those who spend so much of their lives in relieving the out-patient sick and lame.

CONSUMPTION AND ORDER OF BIRTH.*

BY W. C. RIVERS, M.R.C.S. ENG., L.R.C.P. LOND., D.P.H.,
RESIDENT MEDICAL OFFICER, NORTHUMBERLAND SANATORIUM.

WHEN holding a resident post at the Crossley Sanatorium in 1906, the present writer observed in the patients' case sheets, which showed ordinal position in the family, a large number of entries of eldest-born children; and from this observation conceived the idea that clinical pulmonary tuberculosis might affect such persons more than others. Wishing for expert mathematical opinion on the point, he forwarded the material, mentioning[1] the observation made, to Professor Karl Pearson. The conclusion[2] this distinguished mathematician reached was that both first- and second-born offspring appear subject to consumption at a very much higher rate than younger members of a family.

What follows is an independent examination of fresh evidence bearing upon this matter, and falling under three heads—material, literature of the subject, and conclusions.

A. MATERIAL.

Sources of information suitable to the purpose are, however, very scarce. The shortcomings of medical literature as regards the study of possible pathological inheritance have been much commented upon lately. Author after author records cases of consumption occurring in one or more generations, but until recently no one appreciated the advantage to be gained by giving every available particular. On the side of genealogy and heraldry there is indeed a huge literature, but of the many works to be found at the British Museum, seemingly but one (G. E. Cokayne's "Complete Peerage") mentions causes of death, and even this authority disqualifies itself for the present purpose by not stating absolute order of birth. We learn that such and such an individual was "eldest son" or "third daughter," but not which *child*. Besides, still-births are not mentioned, let alone miscarriages. In fact, all the existent material seems to be medical, and to consist of two works by Brehmer, three by Riffel, and some pedigrees collected by the present writer, a few of which last are either in the hands of workers in the Galton Eugenics Laboratory or have already been published in their "Treasury of Human Inheritance."

I. *Brehmer's Cases.*[3]

In two† books Brehmer gives 500 odd cases of consumption, and in 494 out of the 500 states exactly both the size of family and the patient's position therein. The particulars given are, however, not enough to construct pedigrees from. The cases are grouped into eight rather recondite classifications of this author's devising, but although each set of cases is selected, yet in sum the selection becomes largely neutralised. The present purpose is affected, however—because a population made up of large families will obviously show fewer elder-born than will a population made up of small ones—in two of the classifications which relate to specially large families. These two will be also separately considered. And now to the result of analysis, premising that it is satisfactory to note that Brehmer (who omitted to count up his results) did not affirm elder-born incidence of consumption: his general impression was that in certain instances scrofula affected the earlier offspring, and that in large families the later-born were likely to be consumptive, especially the sixth. It has been said that we are given the size of the family and the patient's order of birth; from these data the following simple calculation‡ may be made (Table I.):—

TABLE I.

Order of birth.	Subjects.	Phthisical patients.	
		Expected.	Actual.
1st	494	73·1	90
2nd	478	70·8	80
3rd	453	67·1	67
4th	412	61·0	57
5th	355	52·5	37
6th	298	44·1	49
7th	238	35·2	32
8th	187	27·6	23
9th	140	20·7	17
10th	102	15·1	9
11th	68	10·0	15
12th	50	7·4	7
13th	28	4·1	1
14th	14	2·0	1
15th	8	1·1	3
16th	4	0·5	0
17th	2	0·2	0
18th	2	0·2	0
19th	2	0·2	1

Total number of actual patients, 494.

It will be seen that instead of an even distribution of consumptives throughout these families, which was to be expected—Pearson, with his notable statistical acumen specially trained to this sort of problem, could conceive of no lurking fallacy here—instead, then, of an even distribution, there is distinct excess amongst first- and second-born. And the data from which this result emerges include, as stated, two sets of especially large families, which will naturally show relatively fewer elder-born consumptives, and as a fact show hardly any, as seen in Table II.

Brehmer's case-histories thus reveal, unknown to their author, an especial incidence of consumption on first, and to a less degree on second, born children. There is also excess of consumption amongst the sixth-born.

II. *Riffel's Records.*[4]

These—records of several generations of the populations of South German villages—are vastly larger and fuller than the preceding, affording thus scope for much more detailed analysis. But first of all note must be taken of some severe

* This refers to first-, second-, third-born, &c., of one *mother*

† More than nine-tenths of the material is in one of them.

‡ Probably no material exists, as yet, which is at once large and exact enough to warrant the highly desirable detailed inferences obtainable by mathematicians, and the many sub-relationships to be searched for by the medical observer. But it requires no high mathematics to determine special incidence relating to order of birth, nor did Pearson employ any when examining this point in "A First Study of the Statistics of Pulmonary Tuberculosis."

TABLE II.

Total number of actual patients, 146.

criticisms passed upon Riffel by Cornet in the latter's well-known work.[5] What Cornet censured, however, was none of the publications treated of here, but a smaller, earlier one.[6] In this he described many inaccuracies, but neglected to give chapter and verse for them. Riffel replied[7] that, excluding some obvious printer's errors, what Cornet took for discrepancies merely arose from the fact that the same Christian name often occurred repeatedly in a family. The arrangement of this early work is not such as to make it easy to decide which is right; but its later, amplified form ("Weitere Pathogenetische Studien"), and the other two works mentioned, admit of several tests being applied.

Tests of validity of Riffel's records.—One turns first, of course, to the distribution of the whole population according to family order of birth. It comes out as in the following table (III.):—

TABLE III.

Erblichkeit und Infektiosität.	Weitere Pathogenetische Studien.	Schwindsucht und Krebs.	Order of birth.
Per cent.	Per cent.	Per cent.	
795 (20·1)	529 (16·3)	553 (16·3)	1st
727 (18·1)	478 (14·7)	530 (15·7)	2nd
627 (15·9)	477 (14·7)	481 (14·2)	3rd
514 (13·0)	436 (13·4)	421 (12·4)	4th
396 (10·0)	370 (11·4)	358 (10·6)	5th
299 (7·5)	290 (8·9)	304 (9·0)	6th
214 (5·4)	234 (7·2)	240 (7·1)	7th
143 (3·6)	154 (4·7)	179 (5·3)	8th
91 (2·3)	105 (3·2)	127 (3·7)	9th
61 (1·5)	69 (2·1)	81 (2·4)	10th
32 (0·8)	43 (1·3)	46 (1·3)	11th
21 (0·5)	21 (0·6)	27 (0·8)	12th
10 (0·2)	14 (0·4)	12 (0·3)	13th
4 (0·1)	7 (0·2)	6 (0·1)	14th
2 (0·05)	3 (0·09)	5 (0·1)	15th
2 (0·05)	1 (0·03)	2 (0·05)	16th
1 (0·02)	1 (0·03)	1 (0·02)	17th
1 (0·02)	1 (0·03)	0 —	18th
0 —	1 (0·03)	0 —	19th
Average size of family 4·8	6·2 (fertile marriages only)	5·4	

In the above it will be seen that the gradations in the successive numbers are fairly uniform, and that in the two latter records there is close general correspondence with the following figures for New South Wales industrial families collected by Powys[8] (Table IV.):—

TABLE IV.

Order of birth.	Per cent.	Order of birth.	Per cent.
1st	7670 (16·5)	9th	1927 (4·1)
2nd	7003 (15·1)	10th	1405 (3·0)
3rd	6184 (13·3)	11th	908 (1·9)
4th	5442 (11·7)	12th	546 (1·1)
5th	4708 (10·1)	13th	311 (0·6)
6th	3986 (8·6)	14th	167 (0·3)
7th	3266 (7·0)	Over 14	209 (0·4)
8th	2593 (5·5)		

Average size of family (fertile marriages only) 6·05.

Here, again, we get in families of similar average size and social status about 16 per cent. of the population eldest-born children.

Secondly, one may examine the number of twin births given in these records, for twinning is known to occur about once in 80 births. In round numbers, twins come in these three investigations respectively once in 111, once in 100, and once in 83 births. The records are certainly not perfect—perfect ones of such dimensions it would be nigh impossible to get, so that this is a fairly satisfactory result. Then the deaths from trauma are far more frequent, as one would expect, among men than among women. Pearson, editing a work of Pope's[9] in which were used "E. & I." and "S. & K.," has remarked that phthisis seems exceptionally rife in this material. It must be remembered that the way of life of these communities (described with unflinching Teutonic frankness) was grossly insanitary. The phthisis death-rate cannot be reckoned because, as already stated, the material is not the contemporary populations of these villages, but the contemporary populations *plus* a good many of their forbears; but in proportion to all deaths the deaths from phthisis were not over-frequent. Thus, in "E. & I." they form 6·2 per cent., in "W. P. S." 7·4 per cent., and in "S. & K." 8·7 per cent. of all deaths mentioned. Now in 1893 the general death-rate for England and Wales was 17·6, and the phthisis death-rate 1·3, to 1000 persons living.[10] This would make the deaths from phthisis 7·3 per cent. of all deaths. And, according to Mr. Garland,[11] in the Ancient Order of Foresters, for the quinquennium ending 1901 the deaths from phthisis were among members 15·1 per cent. of the total deaths; among wives and widows of members 13·2 per cent.; while in the Hearts of Oak Society in 1903 and 1904 deaths from phthisis formed over 17 per cent. of all deaths.

As a last numerical test, although this argument may savour of prolepsis, we may take the incidence of the few cases of insanity mentioned; for, as will be described later, insanity has also been claimed to pick out the elder-born for its victims. In "S. & K." and "E. & I." taken together the incidence is shown in Table V.:—

TABLE V.

1st ... 7 in 1348 (0·5%)	5th ... 2 in 754 (0·2%)	9th ... 1 in 218 (0·4%)
2nd ... 2 in 1257 (0·1%)	6th ... 1 in 603 (0·1%)	10th ... 1 in 142 (0·7%)
3rd ... 0 in 1108 —	7th ... 0 in 454 —	11th ... 0 in 78 —
4th ... 0 in 935 —	8th ... 0 in 322 —	12th ... 0 in 48 —

The value of the above calculation is slight, but nevertheless, allowing for the disturbing influence of small totals in the tenth and later born, it shows eldest-born excess of insanity.

What is, perhaps, more important is the general impression these works make upon the reader, and the estimation in which their author is held in his own country. As regards the first point the verdict is favourable. There are rather many mistakes, but such as would arise from careless reading of the proof sheets and from the formidable nature of the task, while many details are given the actuality of which seems evident. During the period of production of these essays the author seems, too, to have risen to a professional position of some distinction in his native district. That his work has found admirers among other physicians Cornet himself attests, and this was the case so recently as at the 1910 Congress of German practitioners specialising in tuberculosis. Riffel's work may, then, allowing for large unavoidable limitations, be taken as valid.

Inter-comparison of Riffel's three publications.—That there must be such limitations will be obvious to anyone who will

picture to himself the task of accounting for most of the persons born during the last hundred years in even a small village; of getting to know respecting each one his or her parents; date of birth; illnesses, marriages, and children; and date, age, and cause of death. In the present instances the task was, on the one hand, helped by close personal local knowledge and by access to official registers; on the other, hindered by emigration of villagers, which (to North and South America especially) seems to have been frequent. It is useful, then, to ascertain in which of the records these difficulties counted for least, and Table VI. (of percentage frequencies in all births) may do something to show this:—

TABLE VI.

—	Deaths from—					Cases of—	
	Phthisis.	Pneumonia.	Cancer.	Typhus.	Trauma.	Twins.	Still-births and miscarriages.
S. & K.	5·9	2·1	0·5	0·7	0·8	1·2	4·0
W. P. S.	4·5	1·6	1·1	1·1	0·2	1·0	(not given).
E. & I.	4·3	1·1	0·5	0·8	0·2	0·9	2·0

It will be seen that "E. & I." shows slight general inferiority to the other two; and, as we have already seen, the average size of family in this record is 4·8, which for the industrial class seems low, and is certainly lower than that in "S. & K." "E. & I." is, too, the earliest published of the three by nine years. It seems fair to conclude that it must be given less weight than the others.

Incidence of phthisis in Riffel's records according to order of birth.—It has been mentioned that, owing to the nature of the material, it is impossible to give a death-rate from phthisis reckoned in the ordinary way. What will be done first, therefore, is to state percentage frequencies of deaths from phthisis in all the births, thus (Table VII.):—

TABLE VII.—*Schwindsucht und Krebs.*

Order of birth.	Subjects.	Phthisis. Deaths.	Phthisis. Per cent.
1st	553	41	7·4
2nd	530	32	6·0
3rd	481	27	5·6
4th	421	28	6·6
5th	353	21	5·8
6th	304	20	6·5
7th	240	11	4·5
8th	179	10	5·5
9th	127	5	3·9
10th	81	3	3·7
11th	46	2	4·3
12th	27	2	7·4
13th	12	0	—
14th	6	0	—
15th	5	0	—
16th	2	0	—
17th	1	0	—
Total	3373	202	5·9

It will be seen that only the twelfth-born, where the numbers are very small, have proportionately as many deaths from phthisis as the first-born. In subsequent calculations the table just given can be abbreviated, as in none of the records do cases of phthisis occur later than the twelfth-born. Table VIII. represents similarly percentage frequencies, in all births, of deaths from phthisis in "W. P. S."

Here the first, third, fourth, sixth, and seventh born have more than the general average (4·6 per cent.) of deaths from consumption. The seventh-born has the highest percentage of all, but if this table and the preceding one be taken together, first-born children show a larger proportion of consumption than any of the rest. In "E. & I." we come upon the first (and only) record which clearly does not show this (Table IX.).

TABLE VIII.—*Weitere Pathogenetische Studien.*

Order of birth.	Subjects.	Phthisis. Deaths.	Phthisis. Per cent.
1st	529	28	5·2

4th	514	22	4·2
5th	396	20	5·0
6th	299	11	3·6
7th	214	11	5·1
8th	143	3	2·0
9th	91	1	1·0
10th	61	4	6·5
11th	32	0	—
12th	21	2	9·5
Total	3920	170	4·3

But granting that the two more reliable records ("S. & K." and "W. P. S.") show eldest-born incidence of consumption, there remain a good many fallacies to be excluded. The first that will be taken has already been indicated. Even in the best of these records there are many persons whose fate, for one reason or another, is quite uncertain. To deal with this difficulty one may compare the relative incidence of the disease as before—that is, according to position in the family—but amongst those subjects only who are accounted for, that is among all the stated deaths. The result of this examination of the data is in close correspondence with the preceding: "S. & K." shows consumption most rife amongst the eldest-born—11·5 per cent., as against a general average of 8·7 per cent., and a second highest percentage of 9·6 in the fourth-born. "W. P. S." gives general average 7·4 per cent., highest percentage 9·2 in the seventh-born, next highest 8·2 in eldest-born. The two together again show eldest-born the highest of all. "E. & I." again shows the eldest-born below the general percentage.

The second fallacy to be mentioned is not so obvious, but, as will be seen later, it has been imputed by a critic.[12] It is this. Put the case that infantile mortality is especially low in eldest-born children. Then more eldest-born than other children will grow up to adolescence and adult life. The adolescent and adult population will thus come to contain an unduly large proportion of eldest-born; and as consumption is a disease mainly of these ages, consumptives will show an unduly large proportion of eldest-born likewise. To test for this possible fallacy one must limit the material to those who die at adolescent or adult age. The result is, however, entirely negative. "S. & K." gives, in deaths at 18 years § of age and upwards, in the first-born deaths from phthisis 24·1 per cent., which is the highest except in the case of the twelfth-born, whose numbers are very few. "W. P. S." shows, when examined similarly, the first-born proportion highest of all. In "E. & I." the effect of such analysis is to bring the percentage of deaths from phthisis in the first-born column above the general percentage.

But a further procedure which seems desirable is to see what happens in the case of other adult diseases, to see if these, too, are given more frequently in the first-born; for it

§ Osler gives 18 years as the lower limit of the usual age period of phthisis.

is conceivable that the distinctive position of eldest of a family might cause all details respecting him or her to be better remembered. The chief of the other causes of death here recorded, which affect adults, are pneumonia, typhus, cancer, and trauma. The percentages of deaths from each of these four causes have been worked out in each of the three records ("S. & K.," "W. P. S.," and "E. & I.") in the three ways used and just described in the case of phthisis—that is, on all births, on all deaths, and on deaths at 18 years and upwards. In none of the resulting 36 tables does the highest percentage occur with the eldest-born, although in the case of cancer there is some approach to this condition of things. Such an array of figures would be too much to quote in an article of this length, but the following contrast may be given (Table X), using the two records "S. & K." and "E. & I." together, and reckoning the percentages on the first basis, that of all births:—

TABLE X.

Deaths from—	1st	2nd	3rd	4th	5th	6th	7th	8th	9th	10th	11th	12th
Phthisis	6·3	5·0	5·2	5·7	5·2	5·7	5·0	4·8	3·4	3·3	3·3	6·2
Pneumonia ...	1·8	2·5	2·0	1·5	1·3	2·1	2·1	1·8	0·8	2·6	0	0
Typhus	1·2	0·7	1·2	0·7	0·5	1·3	0·4	0·6	1·7	1·3	1·1	0
Cancer	1·2	0·8	1·1	0·9	0·4	0·5	0·6	0·3	1·2	1·3	0	0
Trauma	0·1	0·7	0·6	0·4	0·6	0·5	0·6	0·9	0·4	0	0	2·0

It would, not, therefore, seem to be the case that the especial liability to consumption of the first-born in these two records can be explained on the ground of fuller details of all kinds being given for them, or their greater vulnerability to disease in general.

Before leaving Riffel's notable work one might say that, like Brehmer, he confined himself to comment upon individual or a few cases. He did no computing; and his sole remark connected with position in the family is to the effect that the eldest child or elder children of hereditarily tainted parents escapes or escape consumption. ("W.P.S.," Text, S. 58.)

III. *Own Pedigrees.*

The last source of material is records of sanatorium patients. They relate to sputum-positive cases only, and in many instances information was obtained from parents or other relatives as well as from the patients themselves. What will be used here are the particulars concerning the patients and their brothers and sisters. The record is thus fuller than that of Brehmer, for a complete history as regards consumption is obtained of each family, using that word in the restricted sense of childship, or a series of children born of one mother. My material is, on the other hand, scanty as compared with Riffel's, for it is confined to phthisical families and to one generation, and takes no count of diseases other than consumption.

And here one may protest against the obscurantist argument that it is not justifiable to put down a person as free from consumption unless that person's lungs have been found tubercle-free on the post-mortem table. Were the subject of discussion pulmonary tuberculosis, in the wide sense, then this objection would be valid; but consumption is only those degrees of pulmonary tubercle which become clinically evident. The person who, dying by violence, is found to have a scar at one pulmonary apex, has in the practical problem of tuberculosis no importance at all. For practical purposes, too, lay statements as to deaths of relatives from consumption may surely be accepted to a large extent. Most persons now have a knowledge of what was on the death certificate of a son or sister or brother. But there is, of course, no need for this allowance as regards the patients themselves, for, as already stated, they were fully verified cases of pulmonary phthisis. Their distribution in order of birth works out as in Table XI.

As in Brehmer's material, there is considerable excess of consumption among first and second born. There is also excess amongst fifth born.

If one adds the cases of consumption amongst the patients' brothers and sisters the results are practically the same (Table XII.).

TABLE XI.

Order of birth.	Subjects.	Phthisical patients.

15th	1	0·2	0
16th	1	0·2	0
17th	1	0·2	0

Total of actual cases, 353.

If, to exclude a possible fallacy before mentioned, the distribution of consumption in order of birth is taken among subjects only of 18 years of age and upwards, there is still considerable eldest-born excess (actual 75, expected 60 5) and some second-born excess.

The main examination of material is now finished, and the result may be stated very shortly. Five sources have been analysed, and of these five, four agree in showing that consumption has preference for first- and second-born children. The next step is consideration of the scanty, but interesting, literature of the subject—the literature of what may be called the *pathological aspect of primogeniture.*

B. LITERATURE.

I find no observation previous to my own of eldest-born incidence of consumption. Brehmer's and Riffel's already noted opinions seem the only investigation the subject had received. As to other characters of the first and earlier born, Sir A. Mitchell,[13] among 443 idiots and imbeciles found 138 first-born, or 31·1 per cent. Excluding a large contingent of illegitimate children, who are, of course, disproportionately often first-born, and confining his observations to cases in which only one idiot, and that a congenital one, occurred in a family, he concludes again that "idiocy is more likely to occur among first and latest pregnancies

than among others," since "of *all* the children born in Edinburgh and Glasgow in 1855, 22·8 per cent. were first pregnancies, while of the 85 idiots 33 per cent. were first pregnancies." The first figure in the second quotation seems high, and indeed Langdon Down [14] claims liability to idiocy among primiparous children because 24 per cent. of the 2000 idiots (illegitimate largely excluded) examined by him were first-born children. But Down gives the average size of family (6·91), and also the percentages of idiots who were second-born, third-born, &c. From these data it may be concluded that 24 per cent. was an excess; for, as we have seen in the tests applied to Riffel's work, even in populations with a smaller average size of family the percentage of first-born children to be expected is but 16 or so. He also found that 40 per cent. of idiots born in a state of suspended animation were primiparous children, and invokes as a cause of both phenomena the "exalted emotional life" of newly married couples and the increased difficulties of a first parturition.

Matthews Duncan [15] found that first-born children in Scotland are shorter and lighter than others, but traces this to the influence of early age of the mother. Elsewhere he gives the following summary: "Among Mitchell's 443 idiots and imbeciles 138 were first-born; among Wilbar's 675 there were 191 first-born; among 100 of Beach's, 20; among 2000 of Down's, 480. Or among 3218, 829, or about 26 per cent., were first-born, and presumptively born of young mothers." Voisin [16] has a remark that among the children of an alcoholic father the first is often an idiot, and the second only imbecile. Winter [17] states that 30 out of 54 Irish and Irish-American criminals were eldest-born; there were 9 second, 11 third, 1 fourth, 2 fifth, and 1 sixth born. He connects this with "the theory that first-born children are liable to the greatest number of accidents during birth." Moll [18] gives the following opinion of a patient, a man of considerable intellectual culture: "X. behauptet, er hatte gefunden, dass gerade bei Erstgeborenen sich homosexuelle Neigungen finden." He himself thinks that it is more often in youngest children, but that this is very little more than coincidence.

Carman,[19] after examining 1507 Michigan school children, says that, in general, sensitiveness to pain decreases in order of birth. Strength of grasp remains the same with boys, while it varies with girls. Wells,[20] studying data furnished by trained observers and by teachers of school children in California, gives curves showing, with minor sex differences, first-born children superior to others in weight, height, association time, discrimination, voluntary motor ability, natural mental ability, neatness, and deportment. Macdonald [21] stated that of 53 university students the first-born were more sensitive to pain than the second-born.

Dugdale is quoted by Havelock Ellis [22] as finding that the first-born child tends to be a criminal. This last author seems the first to have been struck with the multiple abnormal tendency of the eldest child, and also to have added to the number of abnormalities those of great talent and genius—for Galton's study of eminent English scientists speaks of oldest or only *sons*, not eldest children. Here it is stated, too, that brothers and sisters dead in infancy are often excluded (at any rate in reckoning average size of family), and this defect is hardly likely to be absent either from Havelock Ellis's material, which is lives from the "Dictionary of National Biography." However, after guarding against some fallacies, Ellis pronounces for decisive results in favour of "special liability for eldest and youngest children to be born with intellectual aptitudes." Ballantyne [23] collects from medical literature the following 23 cases of congenital diaphragmatic hernia, in which order of birth was stated: 1st, 5; 2nd, 7; 4th, 5th, and 6th, 2 each; 8th and 9th, 1 each; order uncertain, but not first, 3.

We now pass to the work of the biometric school, which in this, as in one or two other points, has recently been curiously confirmative of conclusions previously reached by the much, and only in some respects justly, censured writers on the subject known as degeneracy. It begins with a paper [24] by Beeton and Pearson on the inheritance of the duration of life, studied in pedigree records of Quakers. The authors find that "the elder adult sister and adult brother live on an average four years longer than the younger adult sister or brother." An elder brother or sister was "one who might have been born one year or 20 before the younger brother or sister"—a description from which one is not warranted in deducing that the "elder brother or sister" was also the eldest of his or her family, although from subsequent references by Pearson to this paper this would seem to have been often the case.

Next comes the already mentioned study [2] by Pearson of material concerning consumptives collected by the present writer. Next, Heron's study [25] of Dr. Urquhart's 331 family trees of lunatic asylum patients, in which he found excess of insanity amongst the four eldest, and deficiency in the remainder. Pearson in his Boyle lecture [26] quoted the last two findings—namely, that the elder-born are more liable to pulmonary tuberculosis and insanity—and, on the authority of Dr. Goring, added a third, criminality. In two of the instances, then, as has been now seen, the biometricians might have strengthened their case by quoting previous literature. The statistics relating to criminals show excess amongst the first three born, and in the case of the eldest of all it is very marked—viz., expected number of criminals 58, actual number 120.

The conclusion drawn by Pearson, that the eldest-born is generally inferior, elicited a reply from Von den Velden,[12] who took the tuberculous families in Riffel's "Weitere Pathogenetische Studien" and "Schwindsucht und Krebs," and made out that while in them there were certainly more deaths from consumption amongst the three first-born than in the remainder, yet this was due to smaller infantile mortality. This point I have alluded to before. The slight difference described is not enough to account for the much bigger difference in deaths from phthisis, and, moreover, using a much larger material, I have tested for this fallacy with negative results. Finally, Pearson in a letter to the lay press has described eldest-born incidence as characteristic of albinism.

There remain two more medical observations to be mentioned, that of Davidson,[27] who found 10 out of 19 cases of congenital pyloric stenosis to be eldest children; and that of Hunter,[28] who among idiots and their parents described specially heavy incidence at either end of the family. Popular sayings it is not worth while to go into. One or two authors have described abnormalities as especially frequent in bastards, who are likely to be often first-born, and Galton's well-known conclusion as to the relative sterility of heiresses perhaps similarly calls for mention. Pedagogical literature on only children, like Neter's "Das einzige Kind," deals with characteristics referable to a solitary upbringing, and Friedjung [29] invokes much the same cause for the neuropathic and digestive disturbances he found in these subjects.

This is the chief literature of the subject, and, although scanty, it favours Havelock Ellis's supposition of a tendency to multiform abnormality on the part of the eldest child; perhaps second- and third-born children should be included also.

C.—Further Analysis and Conclusions.

There is proof, it is claimed therefore, that consumption has preference for the eldest-born. What further can we learn as to this predilection?

Unfortunately, such inquiries cannot be pushed very far as yet, owing to the want of material. Thus respecting the exact amount of increased risk of developing phthisis that an eldest child runs, no direct data exist from which to calculate. For these the investigator must await records on the scale of Riffel's, but with the blanks much more often filled in. As matters stand, we may say that *whereas in 1228 consumptives* (494 upper middle-class Germans; 353 middle- and lower-class inhabitants of Lancashire, London, and Northumberland; and 381 mainly lower-class Lancastrians) *one should find 196 eldest children, one actually does find 281—i.e., eldest-born consumptives are in excess, say, 40 per cent.*

Has sex any influence—that is, are these first-born consumptives preponderantly male or female? Taking the proportions of male first-born consumptives and female first-born consumptives to, respectively, all male and all female consumptives, Brehmer's record and my own pedigrees show hardly any difference for sex. Riffel's two last works give a slight male preponderance. According to the present evidence, then, the influence of sex is slight, if any.

As to infection, can the greater liability of primiparous children be explained by greater exposure to infection from a parent or other relative? If so, the eldest-born consumptives should come mostly from phthisical parents. The material suitable here is Pearson's study, where the point

received notice, Brehmer's cases, for he gives "hereditarily tainted" families separately, and my own pedigrees. Taking these three sources together the result comes out (Table XIII.):—

TABLE XIII.

Order of birth.	With phthisical parent.			Without phthisical parent.		
	Consumptives.			Consumptives.		
	Expected.	Actual.	Excess.	Expected.	Actual.	Excess.
1st	47·8	74	54%	148·2	207	39%
2nd	46·7	53	13%	143·4	167	16%

Thus the issue of phthisical parents shows the greater eldest-born excess; and although there is the fallacy to be considered that phthisis in a parent will be better remembered by an eldest-born child, yet it seems reasonable to suspect the influence of infection here. But families without phthisical parents also show a distribution of phthisis widely departing from the normal.

Have elder-born consumptives any marked characteristic? Of 141 of my last cases I have full case sheets. The number is far too small to warrant inferences as to peculiarity in the course or extent of the disease, but it may be noted that among these 141 there are one patient with diabetes mellitus, three who suffer from hay fever, and three the subjects of congenital xerodermia. Now, the diabetes case is an eldest child; two of the hay fever patients are likewise, whilst the remaining one is second-born; and two of the ichthyotics are eldest-born. Yet the first- and second-born of these 141 only number 58, and the first-born alone only 28.

This would seem to point to the conclusion that the tendency of the eldest-born to become consumptive is an innate tendency, and the hypothesis is strengthened if we appeal to the literature of the subject. Lunatics and idiots are certainly very liable to consumption, and, as has been seen, it is exceedingly likely that they are disproportionately often eldest-born. Again, if faulty upbringing by inexperienced parents is to be made responsible for consumptive elder children, it must also be made responsible for elder-born criminals, lunatics, idiots and perhaps men of genius, which would render an ordinary human responsibility sufficiently formidable. The existing evidence negatives the view that infection is the sole cause; besides, where does infection come in in the other special classes just named?

Innate tendency to consumption, a soil intrinsically suitable to the tubercle bacillus, phthisical predisposition original and autochthonous, not the result of weakening by other disease, is an idea which has always had support. Bacteriological work may have limited the influence to be properly assigned to it, but an exclusive reliance upon bacteriological arguments has often been proved dangerous; while such theories of the *habitus phthisicus* as stenosis of the upper thoracic aperture, which has considerable vogue in Germany, as the frequency in consumptives of small heart, of a condition of underweight, of supernumerary nipples, and of nasal defect—the evidence as to which last I have given elsewhere—have never been confuted. Eldest-born incidence might unite all these as coördinate degenerative manifestations; and eldest-born incidence, it may be noted, is absolutely proof against the objection, first advanced by Cohnheim, that the *habitus phthisicus* is a result of an already existing tuberculous infection.

Practical applications must as yet be briefly dismissed. There is an obvious bearing upon prophylaxis and upon life and sickness assurance. It may be that the age of nubility has been under-estimated; it may well be that the present limitation of families is a greater evil even than is supposed. But we need to know more of the eldest child's characteristics before speaking positively. The study of the soil, even though it has less therapeutic promise, must not be so overshadowed by the study of the seed. Galton's wise words need marking: "I doubt whether the unaided apprehension of man suffices to distinguish between the frequency of what occurs on an average four times in ten events and one that occurs five times. Much grosser proportions have been wholly overlooked by doctors."

NOTE ON TWO CASES OF TUMOUR OF THE PREFRONTAL LOBE IN CRIMINALS;

WITH REMARKS ON DISORDERS OF SOCIAL CONDUCT IN CASES OF CEREBRAL TUMOUR.

BY W. C. SULLIVAN, M.D. R.U.I.,
MEDICAL OFFICER IN H.M. PRISON SERVICE.

IN the discussion of the mental symptoms produced by new growths in the brain comparatively little attention has been directed to the occurrence of disorders of social conduct, and hardly any reference to the subject is to be found in medico-legal literature. On this account it may be of interest to record the two following cases of brain tumour in which such conduct symptoms appear to have been amongst the earliest indications of the impairment of mental function. The first case came under my personal observation; for the notes of the second case I am indebted to the courtesy of Dr. P. R. Mander, medical officer of H.M. Prison, Pentonville, and lately medical officer at H.M. Prison at Stafford.

CASE 1.—A man, aged 40 years, convicted of larceny in September and sentenced to seven days' imprisonment, and convicted of a like offence in December and sentenced to one month's hard labour. Family history: Father drowned accidentally; mother died from a "paralytic stroke"; maternal aunt stated to have died from "brain disease." Nothing else of note. Previous history: Apparently of normal intelligence as a boy; on leaving school was apprenticed to a plumber, but after a short time ran away and worked his passage to Australia; not prospering there, nor in California, where he went subsequently, he returned to England 15 years ago and finished his apprenticeship. He never did much at his trade, and of recent years got his living mainly by casual labouring jobs. Lately he seemed disinclined to make much effort to get or to retain any sort of work. He married 12 years ago and has had three children, all living and healthy, the youngest three years of age. No history of alcoholism or of lead poisoning; he says he had syphilis 18 years ago.

Circumstances of criminal offences.—Up to the time of his first conviction in September the man had borne an excellent character for honesty. In the month of August he went into West Ham Workhouse, and on Sept. 3rd absconded, taking with him a pair of men's boots. He was traced to a lodging-house, and the boots were discovered concealed in a yard at the rear of the premises. To the police who arrested him he offered no explanation of his conduct, but he told his

wife that he had taken the things because he thought "she might want a pair of boots" (the boots were men's). For this theft he was sent to prison for seven days, and served his sentence without any incident occurring to attract attention to his physical or mental condition. On his release he got some money from his relatives and took a room in a lodging-house, making shift to keep himself and his family by casual work and by what his friends could give him. During this time his wife observed nothing unusual in his demeanour; he had always been rather reserved and taciturn, and he showed no change in this respect. He appeared, however, a little more irritable than heretofore. His health seemed good, but he complained occasionally of dizziness. On Dec. 14th he went out early in the afternoon, and passing by an outhouse where some building materials were lying he went in, took a quantity of lead piping, and proceeded to conceal it by wrapping it round his body under his coat. It was broad daylight at the time, and several men were at work close by; they called a policeman, to whom the man said, "I went into the place and saw it there, and thought I was entitled to it." When charged at the station he remarked, "I know I've done wrong."

Prison history.—On reception the man appeared in good health, and was employed in making coal-sacks; he learned the work rather slowly, taking about five days to pick up the necessary skill which is acquired by most intelligent prisoners in some three days, but after this initial difficulty he did his task satisfactorily. In all other respects, also, he adapted himself to the special conditions and routine of prison-life. On Jan. 1st a complaint about his eyesight led to the discovery that he had intense double optic neuritis. No history of headache, vomiting, or fits could be elicited, but the patient said he suffered occasionally from slight vertigo. Speech appeared rather deliberate (but this, according to information given later by his wife, had always been the case); articulation was distinct. The tongue was protruded straight and was not tremulous. The pupils were equal, regular, and normal in reactions. Gait and motor power generally appeared normal; knee-jerks were increased on both sides. Sensation on face and hands, roughly tested, was normal. Stereognostic sense was normal. As regards mental functions, there was an absence of all evidence of intellectual disorder; the patient gave a perfectly clear and coherent account of his antecedents, the accuracy of his statements being confirmed in all particulars by subsequent inquiries; his memory for recent and remote events was quite good; his orientation in time and place was excellent; he did simple calculations correctly. Emotionally he appeared somewhat apathetic; he seemed quite indifferent to the disgrace and discomfort of imprisonment, and when warned as to the grave condition of his health and the immediate risks to his vision he received the information with an incredulous smile. Beyond this indisposition to accept unpleasant ideas, he showed nothing that could be regarded as morbid optimism; his account of his past and his estimate of his capacity and his prospects in life did not reveal any lack of critical sense. A more detailed examination of the nervous system was unfortunately deferred and was never made, for two days later the patient was found dead in bed. He had got up to pass urine about an hour before, and had spoken in his usual manner to the nurse.

Necropsy.—The organs of the thorax and abdomen were healthy and the body was well nourished. In the brain a large tumour was found infiltrating the left frontal lobe and visible superficially as an oval mass lying obliquely from the anterior pole of the hemisphere to a point close to the junction of the prefrontal sulcus with the fissure of Sylvius. The long diameter of the mass measured 69 mm., and the transverse diameter at its broadest part 50 mm. The growth had destroyed the cortex over nearly the whole of the inferior and over a large part of the second frontal convolutions, and extended deeply into the white matter. The dura mater was non-adherent and was normal in appearance. Microscopically, the tumour was found to be a small-celled sarcoma with very slight development of stroma; in its deeper part it had undergone some degree of calcareous degeneration.

CASE 2 (communicated by Dr. R. P. Mander).—A man, aged 57 years; bridle-cutter. Nothing known of family history. First convicted (vagrancy) in September, 1905. Within the next 11 months was in prison five times for the like offence and once for drunkenness. Died in August, 1906, while serving a sentence of one month's imprisonment.

Prison history.—During his first four terms of imprisonment nothing special was observed about the man's health or conduct. He conformed to the prison routine and did his work satisfactorily. On his fifth conviction, in January, 1906, it was noticed that he had deteriorated mentally; he seemed rather inert and apathetic, and was untidy in his dress and person; he did not answer the school tests nearly as well as on his first admission to prison; he wetted his bed frequently. Despite this appearance of dulness, his memory was fairly good and he talked rationally and coherently. He made no complaint of headache, or indeed of anything, and there was an entire absence of the ordinary symptoms of brain tumour. Speech, motor power, and sensation were normal. Pupils were equal and reacted normally. There was no optic neuritis. Knee-jerks were not modified. On account of his mental condition he was sent to the workhouse at the end of his sentence, but did not stay there long, and was soon back in prison, serving a sentence of seven days in May, and being again convicted in July, 1906, his mental and physical condition at this time appearing much the same as noted above. On the morning of August 9th he was found in a semi-conscious condition in his cell. There was some rigidity of the right arm and right side of face. Pupils were equal; temperature normal; pulse strong and regular; knee-jerks brisk. He was able to swallow fluids. He passed urine under him. During the morning he was restless, continually moving his arms and legs, but taking no notice of anyone. Some hours later pupils became unequal, the face flushed, and pulse became bounding. Then twice in quick succession the face and neck became deeply congested and paled again, after which the pulse gradually stopped.

Necropsy.—Except for some pleuritic adhesions on the left side and some slight evidence of atheromatous degeneration in the aorta, the organs of the thorax were healthy. The abdominal organs were also normal. There was no evidence of syphilis or of alcoholism. In the brain a tumour was found infiltrating the anterior part of the right frontal lobe. It was about the size of a small orange and was of fairly firm consistence. The membranes were thickened over the growth and were firmly adherent to it. There was an area of softening along the posterior margin of the tumour.

Remarks.—Cases of cerebral tumour with an absence of obtrusive mental and physical disorders have, of course, been very frequently recorded; and it is quite natural that, as a mere result of chance, some cases of this sort should be met with amongst prisoners. There is some reason, however, to think that the condition is more common in criminals than would be explained solely on this view. As evidence on the point it may be noted that during the last ten years in the local prisons in England and Wales as many as nine deaths were attributed to brain tumour; and it may be added that five of these cases occurred in three prisons where it is the regular practice to ascertain the cause of death by post-mortem examination. In these three prisons during the period named brain tumour accounted for 4 per cent. of the total mortality, which is a rather high proportion when it is borne in mind that cases of this disease with distinct physical or mental impairment would not be likely to be sent to prison, or, if sent, would not be detained. Whatever be the significance of these figures—and they are, of course, far too few to lay any stress on them—it is at all events clear that disorders of social conduct may occur in the early stages of cerebral tumour, and may apparently be due, as in the cases reported in this paper, to the affection of the brain. In the majority of instances, no doubt, the offences committed in these circumstances are of a trivial sort, and it is perhaps for this reason and because of their precocity, rather than because they are really rare, that so little account is made of them in the literature of the subject. They are, however, in many ways very instructive as throwing light on several points of importance in the relation of crime to organisation, and on that account a short consideration of their characteristics may be of interest.

The first point to be noted in this connexion is that conduct symptoms in brain tumour are generally independent of, and appear earlier than, evidences of intellectual disorder. Here, as in other forms of mental enfeeblement, manifestations in the sphere of impulse and feeling precede the involvement of thought. This fact is illustrated in Case 1, and it is clear in most of the clinical histories

in which any reference is made to the emotional tone and the nature of the impulses. As regards the social quality of conduct in the disease the recorded cases are too few to furnish direct evidence, but it may be inferred from the greater prevalence of the moods of indifference and optimism that the most common sort of delinquency will be either acquisitive or parasitic, as in the two observations reported in this paper. Crime in cerebral tumour would thus show a close correspondence with crime in general paralysis,[1] and in this connexion it is interesting to note how exactly the thefts committed by the patient in Case 1 recall, in their method and in the culprit's attitude towards them, the impulsive larcencies of a general paralytic in what Legrand du Saule has aptly termed the medico-legal stage of the disease. In a case of cysticercus of the brain[2] I have observed petty thieving with the same puerile characteristics as an initial evidence of mental disorder in a patient previously honest and intelligent. The resemblance to general paralysis may be noted also in cases of cerebral tumour with aggressive tendencies; in both diseases such tendencies are usually attributed in the clinical histories to emotional instability and loss of inhibitory control. In addition to such cases there are also instances, though very much rarer, where impulses of violence appear to be related to a persistent affective state. A very remarkable case of this sort has been reported in a preliminary note by Dr. R. Cunyngham Brown of H.M. Convict Prison, Parkhurst, who has kindly allowed me to refer to the clinical history. The patient, who was stated by the police to be a heavy drinker, murdered his wife; while awaiting trial, he complained of visual and auditory hallucinations, and developed a persecutory delirium; after a period of remission the persecutory symptoms recurred with increasing mental confusion and apathy, and the patient died some 17 months after the date of the crime. At the post-mortem examination a large tumour was found infiltrating the right temporo-sphenoidal lobe. So far as I am aware, this is the only case on record of actual homicide in this disease. Cases with suicidal tendencies appear to be much more frequent, and suicidal attempts are mentioned in a large number of clinical histories. Probably in most instances, as Clouston[3] remarks, these attempts are due to intensity of suffering and to despair, and are not, therefore, really the expression of a morbid affective state. Sometimes, however, direct suicidal impulses are observed, mainly, of course, in cases with melancholic depression, and it may then happen that the coexisting enfeeblement of mind gives a special character of fatuousness to the suicidal act, exactly as occurs in general paralysis. A characteristic instance of this kind has been recorded by Siemens,[4] in which the patient, a woman just past the climacteric, with a sarcoma affecting the ascending and first frontal convolutions, developed persecutory ideas and tried to drown herself, but called for help as soon as she got into the water. Actual suicide, however, appears to be a very rare occurrence in cerebral tumour; I have only found one case mentioned in the literature of the disease (a case reported by Rey[5]); and in a series of 1700 post-mortem examinations of suicides recorded by Pilcz[6] new growths were found in the brain in only three cases. Though sexual excitement is often mentioned in the clinical histories, I do not know of any instance in which the symptom led to criminal conduct.

The affective tone and the character of the impulses, like the other complex mental symptoms of cerebral tumour, seem to be quite independent of the site or nature of the growth. As Schuster[7] has shown in his elaborate statistical study of this question, tumours alike in histological character and affecting the same region of the brain may give rise to the most varied manifestations in impulse, feeling, and thought. And the recent figures of Pfeifer[8] support the same view. From this fact we may probably infer that in cases of tumour, as in cerebral enfeeblement from other causes, the character of conduct is determined, not by the brain lesion, but by the state of the organic life, "in which the emotions and the will are rooted" (Maudsley). This is what we find also in the study of crime in alcoholism[9] and in general paralysis, and in all likelihood it holds true as well of the conduct disorders in old age. In alcoholism where there is ordinarily a more or less marked impairment of visceral function, the affective tone which reflects this function is pessimistic, and there is a special tendency to impulses of repulsion, of antagonism to the environment—impulses which find extreme expression in the suicidal and homicidal acts so frequent in the alcoholic. This persistent visceral disorder appears, in fact, to be of somewhat similar nature to the organic changes which, occurring in a healthy individual as the reflex result of unpleasant stimuli, give rise to the depressing emotions, so that in alcoholism the organism is, as it were, constantly attuned to the impulses which belong to these emotions and which are indeed fundamental factors in their constitution. In general paralysis, on the other hand, the organic stimuli which go to form the cœnæsthesis are ordinarily normal, and the affective tone is accordingly optimistic with impulses of attraction, of acquisitiveness. And as the organic condition in cases of cerebral tumour is also ordinarily healthy, the emotional tone and the impulses will for the most part be like the emotional tone and the impulses of the paralytic. And confirmation of this view may frequently be found also in exceptional cases of either disease. Thus in the relatively rare instances of melancholic depression in general paralysis, the emotional state may very often be found to be associated with the presence of some cause likely to interfere with the healthy activity of the organic life, in some cases with senile changes, in others with intoxication by alcohol[10] or by lead.[11] And so, too, in cerebral tumour; taking, for instance, the observations already mentioned, we find that in Rey's case of suicide the patient was 74 years of age, Dr. Cunyngham Brown's homicidal criminal was a heavy drinker, and Siemens' suicidal patient was at the menopause.

The conclusion to which we are led is, then, that the cerebral lesion is related to the disorder of conduct only in so far that by reducing the intellectual life it increases the predominance of the affective life and diminishes control over the organic tendencies, allowing impulse to issue more readily in action. The disease has, therefore, no direct influence on the affective tone or on the character of the impulses; and we could hardly, indeed, imagine it exercising any such influence without admitting a localisation of the feelings for which physiology affords no sort of warrant. The farthest limit to which we can go in this direction has been clearly indicated by Dr. Mott[12] in his recent valuable lectures on the physiology of the emotions. He points out that the only evidence, clinical or experimental, which tends to show a connexion of any special region of the brain with emotion is that which indicates the possibility of the optic thalamus being "the great subconscious centre for the elaboration and coördination of sensory impressions and those brought by the special senses from the material world around." On this view we could conceive that a lesion affecting the thalamus might give rise directly to those diffused peripheral changes which we feel as an emotion, but we cannot in any other way, or with regard to any other part of the brain, imagine a diseased condition of that organ being *per se* the cause of a definite affective state. It is not, therefore, in the condition of the brain that we are to look for the source of morbid feeling and conduct in such instances as we have been considering, but in the activity of the visceral functions, in "these organic effects of the physiological consensus of organs which determine at bottom the play of the affective nature" (Maudsley).

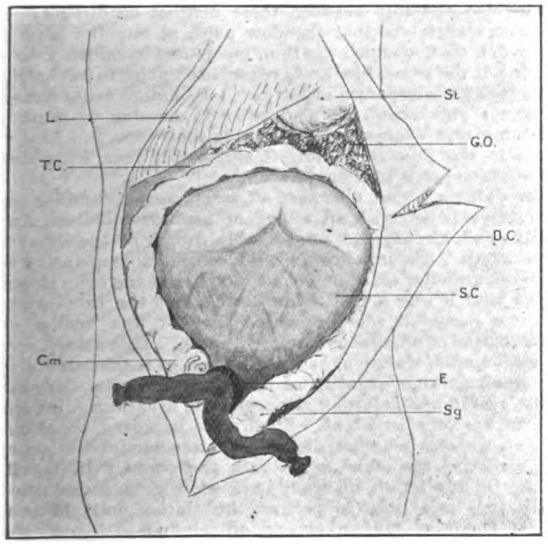
WIGAN INFIRMARY OUTDOOR DEPARTMENT.—At the Wigan Infirmary 10,000 patients are treated annually. The mayor, Mr. Sam Wood, during his four years of office, has tried various devices to raise £10,000 to erect and equip a new out-patient department, but he has succeeded in securing less than one-third of this sum. On Sept. 23rd a money-raising scheme took the form of a carnival procession through the principal streets with a "Pageant of Empire" at the Central Park, but it is to be feared that the rain counteracted the expected pecuniary benefits



STRANGULATION BY VOLVULUS IN AN ABNORMAL SAC LYING WITHIN THE GENERAL PERITONEAL CAVITY.

BY R. LAWFORD KNAGGS, M.C. CANTAB., F.R.C.S. ENG.,
PROFESSOR OF SURGERY IN THE UNIVERSITY OF LEEDS; SURGEON TO THE LEEDS GENERAL INFIRMARY.

THE subject of the condition described below was a man, aged 46, who was admitted to the Leeds General Infirmary on August 3rd, 1908, in a moribund condition, and who died without any operation having been performed. He had been under the care of Mr. W. W. Walker of Batley with symptoms of acute intestinal obstruction which had begun five days before, and had resolutely refused to come into the infirmary till the day of admission. There had been no preliminary warnings of intestinal trouble previous to the sudden onset of acute symptoms.

When the abdomen was opened at the necropsy a very unusual and interesting state of its contents was disclosed. Occupying the mid-region of the cavity was a large rounded cyst or sac, through the semi-transparent wall of which distended coils of bowel could be seen. The upper coils were large and pale, and had a somewhat transverse direction; the lower were black, as if the subject of strangulation, and had an obliquely vertical arrangement. Below the cyst, the lower portion of the abdomen, which was little more than the pelvis, was occupied by coils of black small intestine which concealed the terminal portion of the large gut. Above the cyst, and encroaching on its shelving upper surface, lay the liver, and in the left hypochondrium the stomach. The great omentum was huddled up into a mass which fitted into the space between the cyst and the stomach. The colon was not visible, but it was found to encircle the cyst, except at its lowest part, and to be attached to its wall in a manner subsequently to be described. (Fig. 1.)

FIG. 1.

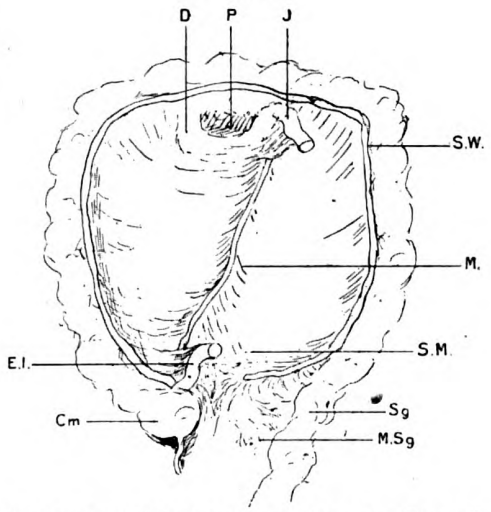
To permit of the further investigation of parts the strangulated small bowel occupying the area below the cyst was removed. It was a single loop some three or four feet long and the two ends of the loop passed into the cyst through an aperture on its lower surface. The two ends were tied a few inches from the aperture, as represented in the illustration. The whole loop was deeply congested, of a purplish-black colour, and infiltrated with blood. It was not constricted at the neck, and the finger could be introduced alongside the gut through the aperture into the cyst. The entrance to the sac looked downwards and was on the level of the promontory of the sacrum. It was large enough to admit three fingers. The cyst, which will now be referred to as "the sac," occupied the small intestine area within the arch of the colon. To continue the examination it was opened by a central vertical incision through its whole length which terminated by dividing the boundary of the aperture.

For the sake of simplicity the cause of the strangulation will be dealt with at once. The two cut ends of the strangled loop were continuous with similarly affected coils within the sac. There had been no strangulation by the neck of the sac, and no signs of constriction were presented by the portions of bowel that occupied it. The greater part of the ileum was in this deeply congested state which was evidently due to a twist of the lower portion of the mesentery, but the exact mechanism was not made out, as owing to the inexperience of the manipulator the relations were disturbed and lost, and the previous removal of the loop outside the sac added to the difficulties of its demonstration. The jejunum was distended but not strangled.

The small intestine was now removed from the upper end of the jejunum to the lower portion of the ileum. By this the whole cavity of the sac was displayed. On its posterior surface was the quite normal attachment of the mesentery. It lay entirely within the sac. At the upper part the third and fourth parts of the duodenum were in their natural position and covered as usual by peritoneum. The terminal portion of the ileum passed out of the opening to join the cæcum, which lay just outside and to the right of the mouth of the sac. The ileum at this point was attached by its mesentery, which blended with the margin of the aperture on the right side. (Fig. 2.) The condition may be fairly

FIG. 2.



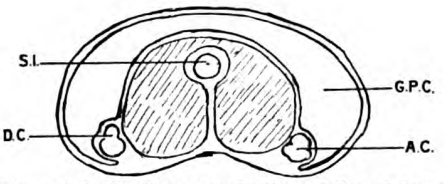


Diagram to show the posterior wall of the sac. The small intestine with its mesentery has been cut away as well as the anterior wall. J., Jejunum. P., Pancreas. D., Duodenum. described as a second and abnormal lesser peritoneal sac, whose natural contents were the small intestine and its mesentery. Some of the contents had escaped through the orifice into the general peritoneal cavity.

The actual anatomical disposition of the peritoneum can most easily be explained by the help of diagrams. Tracing the peritoneum in a horizontal direction (Fig. 3) about the middle of the sac and beginning with the outer layer of its anterior wall it could be followed to the descending colon, which it invested without forming a mesocolon. It was then reflected on to the anterior abdominal wall and lined the parietes till it reached the ascending colon. After investing this—also without forming a mesocolon—it was continued on the anterior wall of the sac to the point from which a start was made. On the inside of the sac the serous

membrane could be traced from the inner surface of the anterior wall to the right till the posterior abdominal wall was reached, but just before this the ascending colon could be seen lying upon its exterior. Passing to the spine the small intestine was invested and the mesentery formed. The posterior abdominal wall was then covered on the left side,

FIG. 3.

and as the peritoneum was reflected to the anterior wall of the sac to reach the point from which it started it skirted the descending colon which lay on its outer surface.

A study of Fig. 2 will make plain the way in which the terminal part of the ileum was tethered to the margin of the neck of the sac by the two layers of its mesentery which diverged to become continuous with the peritoneal covering of the aperture. A vertical section through the mouth shows how the two layers of peritoneum by which the anterior wall was formed blended at the free margin and also how the posterior peritoneal lining of the sac was continuous with the peritoneum lining the pelvis. (Fig. 4.) The neck of the

FIG. 4.

sac contained no large vessels, but it was slightly rounded and thickened. The anterior sac wall was also destitute of vessels of any size.

It is evident that this unusual condition was in no sense a hernia, and that consequently, notwithstanding a certain suggestive similarity in appearance, the pathology must be quite different from that of the various forms of internal abdominal herniæ. I have discussed the case on several occasions very carefully with Professor J. Kay Jamieson, who has referred me to a paper by Dr. J. Cameron and Dr. J. D. Lickley,[1] in which is described an abnormal peritoneal sac very similar to this one, but without any aperture; and also to the report of another case by Professor Clelland (mentioned in their paper) which would appear to have some resemblance to it. I had hoped that Professor Jamieson would have joined me in this communication and given a description of the way in which such a condition might arise in the process of development, but at the present time he feels unwilling to commit himself to an explanation which subsequent research may show to be incorrect. As the whole subject is one in which he is much interested it has been decided that the case shall be published now, and at some future date he may in a separate communication deal with the condition from the anatomical standpoint.

Personally I believe that the abnormal sac is a consequence of an irregularity occurring during the evolution of the large intestine. With a piece of rubber tubing to represent the bowel and a towel to constitute the mesentery, it is quite easy by imitating the normal rotation of the colon and the passage of the cæcum to the right side to produce a sac, such as existed in this case, either by the formation of a fold in the mesocolon and its adhesion to the posterior parietes, or by adhesion at some point of the right peritoneal layer of the mesocolon. But I must content myself with this simple statement, for the description of the manner of its production —in such a way that it could be understood—is beyond me.

Leeds.

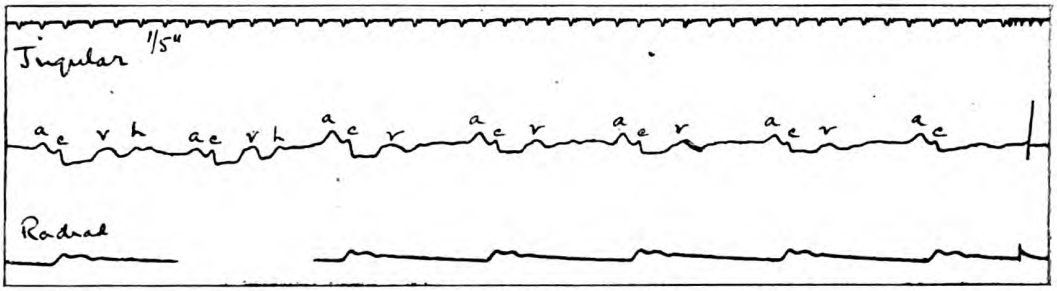
BRADYCARDIA IN ASSOCIATION WITH URÆMIA.

BY E. E. LASLETT, M.D. VICT., B.SC. LOND.

IT is well known that an infrequent pulse is occasionally associated with some forms of toxæmia, particularly those which accompany catarrhal jaundice and chronic nephritis. An infrequent pulse may be due to three different causes: (1) the regular occurrence of extra-systoles not perceptible to the finger on the pulse (coupled rhythm); (2) heart block, partial or complete; and (3) slowing of the whole heart. It is only since the introduction of the graphic method of studying heart affections that it has become possible to distinguish certainly between these distinct conditions. It has been ascertained that the slow pulse of jaundice is most often due to a coupled rhythm, much less commonly to a slowing of the whole heart. As regards the pulse in nephritis, little is at present known either as to its nature or its cause. It is not yet considered as proved to be due to uræmic poisoning, and Vaquez and Esmein,[1] in their report on Bradycardia to the French Medical Congress last year, state that the question needs further research.

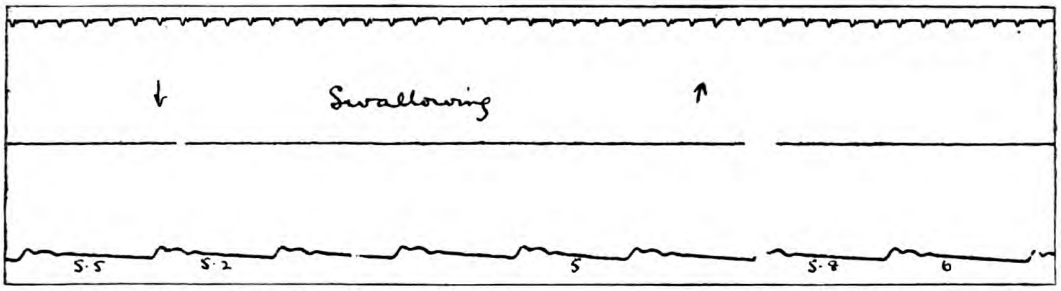
The patient, a man now aged 42 years, was first under my care six years ago with an attack of nephritis. When first seen he had already had considerable dropsy of the legs for three weeks. The urine contained a considerable quantity of albumin, granular casts, and some blood. At the time it was hoped that it was a first acute attack, but the subsequent progress makes it more probable that it was really an exacerbation of an already chronic disease. This attack was of four months' duration, and at the end of it the urine still contained a large quantity of albumin. In spite of many weeks' rest in bed, careful dieting, and the usual remedies the œdema was very persistent. Finally, he improved considerably on a more generous diet and the free administration of iron, and he was able to go into the country in April, 1906. On his return he went back to work and remained fairly well and able to perform his duties until March, 1908. Then he had an attack of "influenza" and the œdema returned. This time the disease was still more resistant to treatment than before, and he was in bed for over eight months. In spite of all the usual remedies the amount of urine often fell very low and the œdema gradually spread upwards, fluid collected in the abdominal and pleural cavities, and the breathing became at times very distressed, particularly at night. At times there was almost total suppression of urine, and for many weeks the onset of severe uræmia was feared. The exclusion of salt from the diet appeared to have little effect as regards producing diuresis. It may be mentioned here that the patient was extremely fond of



[1] Vaquez and Esmein: Archives des Maladies du Cœur, Paris, December, 1910, p. 732

salt. On his recovery from this attack he was warned to be sparing in his use of this condiment, and it is perhaps noteworthy that he has remained practically free from dropsy up to the present time. Finally, the head of the bed was raised six inches, and the dropsy so encouraged to sag into the lower extremities, whence it was drained off by Southey's tubes. In the course of about two months about 50 pints of fluid were thus drained away, and in this manner he was kept fairly comfortable, without, however, any striking improvement in the amount of urine. This soon diminished alarmingly whenever the dropsy was allowed to make headway, as when the tube had to be withdrawn. Ultimately the legs became too sore and inflamed to allow of the continuance of this treatment. As a last resort he was put on sodium theocin acetate (with digitalis), which had not previously been tried. The result was most striking. In a week the œdema had practically disappeared. He then gradually improved, and he was able to resume his work in March, 1909, after a year's illness. His systolic blood pressure taken on several occasions during the illness ranged about 160–165 mm. Hg (Oliver). Curves were taken on several occasions from the radial pulse. Nothing abnormal in the rate of the pulse was ever met with during this illness. Since that time he has kept remarkably well. Except for about a fortnight, when he was operated on for ischio-rectal abscess, he has been steadily at work. His wife has at intervals roughly tested the urine for albumin by boiling, and she states that the amount of coagulum diminished very considerably. During the latter part of February of this year it had, however, again increased, and he had not been quite so well, although he remained at work.

His present attack began suddenly in March. On the 18th he got a chill while working late at night in an exposed place. Next day the temperature was 101° F., pulse 80 per minute, and there were a few rhonchi in the lungs. The urine was not measured, but it had diminished considerably. Next day the temperature was normal, pulse 64–70. The urine had still further diminished. It was smoky and loaded with albumin. On the 22nd the urine was less than 10 oz He was now rather drowsy, complained of constant headache, and vomited several times. The eyelids were rather puffy, but there was no œdema of the legs. The pulse-rate had now fallen to 42. The skin was reacting well to treatment and the bowels had been well moved. Next morning he was about the same. He had passed no urine for 12 hours. The pulse was still slow, slightly varying in rate, but 46 per minute on the average. Later he passed urine and on the following day he was brighter. Urine for the past 24 hours 10 oz. The pulse-rate had now risen to 50. With further diaphoresis and purging he progressed rapidly. The urine increased and coincidently with that the rate of the pulse. On the 27th he was passing urine freely, and the pulse-rate was now normal at 70–72. He was kept in bed a week longer, and in another week he was able to resume his work. The blood pressure, measured when the pulse was slow, was found to be 150 mm. Hg, systolic (Hill).



From the curve in Fig. 1 it is evident that it is a question of a slowing of the whole heart, auricles and ventricles being equally affected. The *a.-c.* interval is normal. Although it was not deemed advisable to apply the atropine test, it seems justifiable to attribute the slowing of the heart to heightened vagus control. There was a slight degree of sinus arrhythmia, dependent upon respiration. Occasionally this was more marked, as the following pulse intervals (in fifths of a second) show—6·2, 6, 5·9, 5·6 (inspiration), 6, 6·8, 7.

FIG. 1.

Simultaneous curves of the jugular and radial pulses, to show that auricles and ventricles are equally affected. The *a.-c.* interval is normal. Pulse-rate 46 per minute March 23rd, 1911.

FIG. 2.

Shows the increase in pulse-rate due to a series of swallowing movements, the duration of which is indicated by the arrows. March 23rd, 1911.

Exertion slightly quickened the pulse-rate. Further, two or three swallowing movements made in succession definitely increased the rate temporarily, which slowed again just after the last swallowing movement (Fig. 2).

Danielopolu[2] has recently reported two cases of bradycardia observed in the course of nephritis. In both cases the slow pulse was due to a true bradycardia from increased inhibition. In one of the cases the development of the slow pulse was observed, and the writer considers that there is good evidence that the bradycardia was due to uræmic intoxication. In the present case the infrequent pulse was due to a true bradycardia. It was a new feature, never having been observed in his previous acute attacks, and inasmuch as the gradual development of the bradycardia coincided with the onset of uræmic symptoms, and its cessation with the increase of the urine and the disappearance of the dangerous symptoms of poisoning, it is at least very suggestive that the

[2] Danielopolu: Archives des Maladies du Cœur, Paris, July, 1911 p. 417.

condition of the heart was due to the uræmic poison acting probably through the inhibitory mechanism. The fact that the bradycardia was observed only in the last attack and never during the previous long illnesses may possibly be related to the acuteness of onset of the symptoms of uræmia and the rapid diminution of urine.

Hull.

OPEN-ETHER ANÆSTHESIA:
SOME IMPROVEMENTS.

BY J. ROBERTSON, M.D., CH.M. ABERD.,
SENIOR ASSISTANT ANÆSTHETIST, ABERDEEN ROYAL INFIRMARY.

AT the present time there is no need to enlarge on the claims of ether anæsthesia by the open method. They are generally recognised. For the past 18 months it has been my custom to employ this form of anæsthesia. The number of cases at the Aberdeen Royal Infirmary anæsthetised by me in this manner is 400, and on the records of these the following remarks are based. I have no fault to find with chloroform, except that it is a drug with which one may do more harm of a really dangerous character than ether; and therefore if as good results can be got with ether it is our duty to the patient as anæsthetists to use it

It used to be said that it was impossible to anæsthetise a person with ether alone, and it is true there are difficulties. These difficulties have brought about the general plan of putting the patient "under" with chloroform first, and then instituting open-ether anæsthesia. I have endeavoured to avoid doing this, and have succeeded in all but two cases in giving ether from start to finish. The modern major operation is often prolonged, and may involve extensive interference with anatomy and with physiological processes. In such cases there is little call for administering any anæsthetic which will encumber the vital organs. Chloroform, or ether by the close method, will certainly do this. The period of induction of anæsthesia is with chloroform fruitful of danger, and it is desirable, therefore, to exclude it even as a preliminary.

The method employed here is very simple. Several layers of ordinary white gauze are put into a Schimmelbusch's frame, so forming a mask, which is placed over the patient's mouth and nose. Ether is dropped on this from an ordinary drop-bottle, and the vapour so produced is intensified gradually by winding a roll of white gauze round the edge of the mask, perhaps adding a fold or two to the thickness of the mask itself. In six minutes the patient is anæsthetised, and during this time the preparation of the skin for incision can be actively proceeded with and the patient placed in the Trendelenburg position if necessary.

When this method was first tried it required from 3 to 4 oz. of ether to put the patient "under," sometimes even more; but the improvements which I will endeavour to describe have greatly reduced both the quantity of ether and the time necessary for full anæsthesia. The total quantity used was often 10 to 15 oz., but we have succeeded in reducing this to from 1½ to 2 oz., even for a long operation, with very few exceptions.

The difficulties met with in putting a patient "under" ether are that in many cases spasm of the jaws and glottis takes place at an early stage, and however much ether is poured on very little is inhaled and a great deal escapes into the room. Again, the vapour is apt to cause increased secretion of mucus and saliva, which collects in the pharynx and larynx, becoming converted into foam by agitation during the movements of respiration. This adds another obstruction to the inhalation of ether, and a certain amount of cyanosis takes place with great delay in the induction of anæsthesia. I know of nothing which will remedy this condition readily, for to mop out the throat only serves to stimulate the mucous membrane to further secretion during the second stage of induction, and any such attempt is greatly resented by the clenched jaws. Sharp rubbing of the lips and nostrils with a towel sometimes helps. As full anæsthesia is reached these adverse conditions gradually disappear, the mucus is swallowed, the jaws relax, and the colour improves. But should the patient be allowed, even for a short time, to return to the second stage, as may happen if the patient is moved about, all the difficulties reappear.

In my experience, seven out of every ten cases present those difficulties in varying degrees, where no preliminary treatment of the patient has been resorted to. If, however, 1/100th gr. of atropine sulphate is given in conjunction with 1/6th gr. of morphine, hypodermically half an hour before operation, it is very rare to find any of these difficulties, and in these rare cases it will be found that the injection has been too superficially given. I have records of 280 cases treated this way. The injection soothes the patient's mind before operation, and prevents spasm of the air-passages and jaws. Anything like the chloroform excitement stage is never met. The shock of operation is, to a large extent, prevented by rendering the brain centres less sensitive to afferent impulses from the operation area. Mucus secretion in the throat is greatly lessened. There is never any cyanosis or dyspnœa to speak of. Less ether is used because more is really inhaled. There is practically no sickness, and the patient remains in a comfortable sleep for several hours, which has naturally a good post-operative effect.

The value of omnopon[1] in the administration of ether has been brought before your readers by Mr. H. M. W. Gray's experiments, an account of which was published in THE LANCET of Sept. 2nd. For the first three or four months of these tests I had to administer ether in the omnopon cases very frequently. The number of cases of omno-ether anæsthesia at the hospital is 220. Lately, the number of cases requiring ether—i.e., where omnopon and local anæsthesia have been insufficient—has been much reduced, chiefly due, I think, to the skill Mr. Gray has acquired in injecting the novocaine. He welcomes honest criticism, and will not mind my remarking on the extraordinary complexities of the pharmacological question involved in his form of anæsthesia. First, there are the various alkaloids in omnopon, numbering something like 15. Add to that scopolamine, novocaine, adrenalin, and finally in 20 per cent. of cases (his own figures) ether, and one has a medley of empiricism which appears regrettable.

The type of anæsthesia which I advocate—viz., omno-ether—is certainly open, but to a lesser extent, to the criticism of pharmacological complexity, but I think it will be found to excel most other forms of anæsthesia, pending the perfection of the ether "Narkose intravenöse," which is still only on trial.

Let the patient have a deep subcutaneous injection of one dose of omnopon, at any rate an hour previous to operation. This may be given by the nurse. It will be found, when the patient is placed on the operating table, that he is in a slightly sleepy condition. Place the mask over the nose and mouth, and in three or four minutes, as a general rule, having administered half to one ounce of ether, the patient is snoring comfortably and absolutely lax. No difficulty is experienced in maintaining this condition with another half-ounce of ether for an hour. I heard the condition lately described, and I think well, as synthetic sleep. The pupils are slightly contracted and react to light. I have noticed in some cases slight and temporary divergent strabismus. The conjunctival reflex is absent. The face is slightly flushed a pink colour. The pulse is full and steady. The respirations are slow and deep, perhaps 12 to 15 a minute. There is no mucus production in the throat, and no spasm or tremor. After a three hours' operation the patient is practically in the same condition as at the start.

Where an effort has been made to perform the operation with local anæsthesia, and for that reason a larger dose—say 1½ to 2 ampoules—of omnopon has been given, the respirations may be reduced greatly in rapidity, giving some anxiety, but a little ether inhaled will accelerate them again. In such cases I have seen the respirations slow down gradually, even when ether is being given, but only after a very prolonged operation. Oxygen will then be found of value. With these exceptions, none of the omno-ether cases have ever given me the slightest anxiety during the administration, nor have there been any injurious after-effects. Pathological lesions in the heart, lungs, or kidneys seem to be no drawback to ether anæsthesia by this method, as far as our experience goes. There has been no selection of cases whatever.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

NOTES ON A CASE OF PERSISTENT CHYLURIA MARKEDLY INFLUENCED BY POSTURE.

BY FRANK CHARTERIS, M.D. GLASG.,
DISPENSARY PHYSICIAN, GLASGOW WESTERN INFIRMARY.

CHYLURIA results from an abnormal communication of a lymphatic vessel with the urinary tract. In this country it is uncommon, but in tropical regions, where filariasis is endemic, chyluria is common. The filaria either causes an obstruction by blocking up the lymphatic tract, or the obstruction may be the result of secondary changes of an inflammatory type induced by the presence of the filaria. In either case the lymphatics distal to the obstruction become varicose, and chyluria is set up if one of the distended vessels ruptures into the patent urinary tract. It is obvious that any other obstruction, apart from filaria, which interferes with the normal passage of chyle and lymph through the thoracic duct may also cause chyluria by setting up, first, distension and varicosity of the vessels distal to the obstruction, and then rupture of one of the distended vessels. As a matter of fact, chyluria apart from filariasis seems very uncommon. Lüdke[1] in 1908 was only able to collect ten cases of non-parasitic chyluria from published records. The case which I now record seems also to be an instance of non-parasitic chyluria.

The patient is an Austrian, aged 59 years, who noted the chyluria first in May, 1900. In early life he was a sailor and visited Egypt, India, Brazil, America, and the East and West Indies. So far as he knows he never became infected with filaria, but for many years suffered from malaria. Since 1875 he has made his home in Glasgow, and has never been out of the country since 1880. He is an outdoor worker and is also often employed at the fruit market. Apart from repeated attacks of ague he enjoyed good health till May, 1900, when he noticed that every two or three days the morning urine tended to be very milky. Two months later he began to suffer from dull pain and uneasiness in the loins after working hard or lying long in the same position. After this had gone on for some ten weeks he woke up one morning and was unable to pass his urine. This inability lasted for some hours, but eventually after severe straining he dislodged a thick clot and was then able to micturate freely. Subsequently he had similar attacks, and on one occasion he noted that blood came along with the clot. About this time he observed that the urine standing overnight clotted.

The patient was admitted to the Western Infirmary under Professor R. Stockman's care in 1902, when the chyluria had persisted for nine months. At that time the urine was very milky, containing fat droplets, lymph cells, epithelium, and a few casts. No filariæ were present. The urine varied in appearance at different periods of the day. When it was chylous it contained albumin but no sugar. It was noted that posture had an important effect upon the urine. If the patient lay down after taking a meal the urine became rapidly chylous. Thus as a rule the chyluria was most evident in the morning, especially if he had taken food just before going to bed. It is interesting to note that in the summer months the morning urine remained much clearer. This seemed to arise from the fact that the patient's occupation necessitated him being out of bed from 2 to 6 A.M. During the time the patient was in hospital chyluria could be induced at any time of the day by giving him a glass of milk and then making him lie on his back. Repeated and systematic examination of the blood failed to demonstrate any filaria even when films were made at two-hourly intervals for a consecutive period of 24 hours.

After a residence of several weeks in hospital the patient went out with the urinary condition practically unaltered. Subsequently I lost sight of him for four years, when he consulted me at the Central Dispensary on one or two occasions. By that time his urine had become much clearer, but was still milky.

In December, 1910, the patient again sought admission to the Western Infirmary on account of gastric disturbance, which was producing flatulence, palpitation, and dizziness. During his stay in hospital it was found that the chyluria still persisted, though it was much less marked than in 1902. Repeated examination of the blood and urine again failed to reveal any filaria. It was found that the chyluria was markedly affected by the position of the patient. When he was upright the urine was practically free from fat, but if he reclined at an angle greater than 45° he promptly began to pass milky urine; but if he sat in an upright chair the urine remained clear. The most milky urine was passed when he lay flat on his back. On the other hand, he could lie flat on his face without the urine becoming milky, but it became milky as soon as he turned round and lay on his back.

The conclusion we came to was that the chyluria was due to some intermittent pressure exerted on the thoracic duct by some factor which only became operative when the patient assumed certain attitudes. Probably the obstruction was a pedunculated calcareous gland. There was no enlargement to be felt in any of the abdominal glands, and an X ray examination failed to reveal any calcareous masses. Still, on the whole, a moveable enlarged gland seems to be the most likely explanation of the intermittent obstruction.

The patient would not allow a cystoscopic examination to be made, so that it was impossible to determine whether the chyle leaked into the bladder or was mixed with urine at a higher portion of the urinary tract. Lüdke was able to show that in his case of chyluria, which developed as a sequel to an inflammation of the bladder due to infection with B. coli, the urine left the ureters free from chyle, but became chylous in the bladder. Hertz[2] examined a case of chyluria and post mortem found the obstruction of the thoracic duct above the diaphragm, and the communicating ruptured lymphatic vessel in the bladder.

Glasgow.

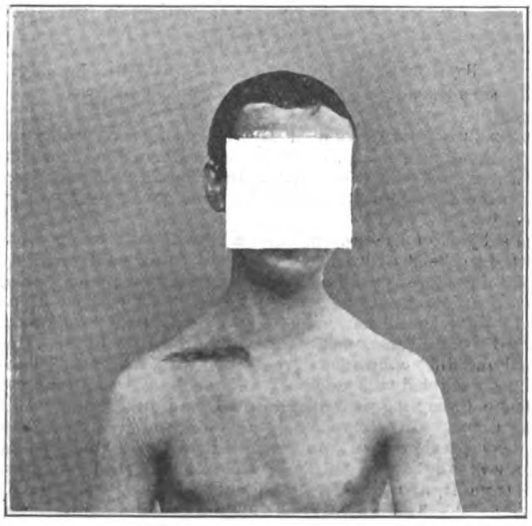
A CASE OF NECROSIS OF ALMOST THE ENTIRE CLAVICLE.

BY ROBERT E HALAHAN, M.D. DURH.,
SURGEON TO THE BRITISH HOSPITAL, BUENOS AIRES.

NECROSIS of the clavicle in the form of scaly sequestra due to tuberculosis, &c., is not a very rare occurrence, but such an extensive involvement of the bone as the following case presented does not seem to have been frequently observed.

The subject of the present case, a man aged 28 years, was admitted to the British Hospital, Buenos Aires, on Jan. 28th, complaining of a swelling on the right clavicular region. He stated that three years before he had been treated in a Manchester hospital for syphilis, when he had a chancre followed by eruptions on the skin of an ulcerative kind. He had 18 months' continuous treatment with mercury. The swelling occupied the root of the neck and the supra-clavicular fossa; it was red, indurated, and not very painful to the touch. The temperature varied from 37° to 38° C. Ten days previously a ship surgeon had made an incision just above the inner third of the clavicle, but no pus came from it, and it was closed when the patient entered the hospital. The wound was again opened and a large quantity of pus escaped. No dead or exposed bone could be found, and the cavity seemed to extend behind the clavicle towards the axilla. A tube was inserted, but the temperature continued high, and a few days after exposed bone was felt with a probe. The wound was now thoroughly opened up under chloroform, and it was found that the whole clavicle was denuded of periosteum and lying in a tube lined by dirty granulations. The bone, which was quite white and clean-looking, like a museum specimen, was still attached by the ends, and no attempt was made to remove it, in the hope that it would act as a stay until the periosteum recovered and began to lay down a new clavicle. Fig. 1 gives a good idea of the condition, though only the inner end of the clavicle can be seen, owing to the camera having been placed too low down. The periosteal tube was split from one

[2] Royal Medical and Chirurgical Society, March, 1907. THE LANCET, March 16th, 1907, p. 733.



end of the clavicle to the other and the wound lightly packed with iodoform gauze. Thirty days later the sequestrum, which became loose, was removed; it consisted of the entire

FIG. 1.

clavicle minus the articular surfaces, which seem to have survived. Gradually the wound closed up and a thick deposit of new bone formed in the site of the clavicle; in

FIG. 2.

fact, a new clavicle has been laid down. There is practically no deformity, as can be seen in Fig. 2, and the arm is functionally sound.

Buenos Aires.

ST. MARY'S HOSPITAL MEDICAL SCHOOL (UNIVERSITY OF LONDON).—The following have been elected to Entrance Scholarships at this school for the year 1911. University scholarships: 50 guineas, A. S. Cohen, University College, Cardiff; 50 guineas, F. A. Williamson, B.A., Queen's College, Cambridge. Open scholarships in natural science: £50, G. E. Barker, Latymer School and Birkbeck College; £25, A. R. Fuller, Leighton Park School, Reading. Epsom College Scholarship: T. R. Davies.

Reviews and Notices of Books.

The King's Evil. By RAYMOND CRAWFURD, M.A., M.D. Oxon., F.R.C.P. Clarendon Press. 1911. Pp. 188. Price 8*s.* 6*d.* net.

PRIMITIVE medicine at the dawn of history, and even at an earlier date, consisted mainly in so-called magical operations—i.e., charms, incantations such as the Homeric ἐπαοιδή, and occasionally the administration of herbs gathered at certain seasons, with appropriate prayers. Such prayers, even in Christian times, were often frankly Pagan, and a good example thereof is to be found in the British Museum (MS. Harl., 1585, fol. 12a ff.) in the shape of a prayer to the great Earth Goddess at the gathering of medicinal herbs. Trephining was known to and practised by our Neolithic forefathers, probably with a view to affording a means of escape for evil spirits; but, on the whole, in early ages medicine was of a less material nature. In process of time medicaments of infinite variety, and often of appalling nastiness, began to be employed, while the methods of surgery were crude and necessarily painful. It is not astonishing, therefore, that the magical methods held their ground, for they offered a *via media* between the repulsiveness of medicine and the anguish of surgery; and it must be remembered that the terms "magical" and "magician" did not originally connote any idea of trickery or deception, but simply conveyed the possession of knowledge.

All knowledge being held to be of divine, or at least of supernatural, origin, it would seem natural that the class of society the members of which were in communion with Deity should possess more knowledge than those who were not so; hence the priest, the prophet, and the king were the repositories of learning, and especially of the healing art or faculty. Of these three classes, the sovereign at first bestowed the healing touch, conferred on him by his "sacring," to the cure of many diseases, but by the time of Henry II. the diseases curable by the royal touch seem to have been narrowed down to two—namely, plague and scrofula. That these two diseases should have flourished in the time of Henry II. is no wonder, if we can believe Peter of Blois's account of the court of that energetic monarch, who, desiring to see with his own eyes, made perpetual progresses up and down the country. The discomfort, the dirt, and the total lack of any sanitary laws during these progresses may be read in the fourteenth letter of Peter, "Ad Clericos Aulæ Regiæ." The lodging was bad; the food was execrable; "sick beasts were sold at random with fishes even four days old." If such was the life at court, that of the common people was probably worse, and there would be no lack of patients for the royal healer to cure.

The King's Evil and the History of the Royal Touch form the subject of the latest treatise in medical history. Dr. Raymond Crawfurd has in this volume expanded his Fitz-Patrick lectures for 1911 into a treatise on the history of the royal touch, which is of extreme interest to all who take thought for the origins of medical custom. The first European king who is recorded to have healed the sick by his royal touch is Robert the Pious (996–1031), who healed "sick folk and chiefly lepers," but Philip I. (1061–1108) and his son Louis VI. (1108–1137) did actually touch for the cure of scrofula, which had not yet acquired the title of *morbus regius*. Healing by touch was apparently then considered a prerogative of the kings of France, for Guibert de Nogent, who records the healing by Philip and his son, concludes by saying that he knows nothing of the power of other kings in this matter, but "I know that the English king makes no attempt to do likewise." Edward the Confessor

had, however, touched for the evil in England shortly before his death in 1066, a rite which he had previously practised when in exile at the Norman Court from 1013 to 1041. He was probably led to this practice by the example of the French kings, as was another monarch, Olaf of Norway (1015–1028). It is true that the healing which Dr. Crawfurd quotes from the Saga reads as if it were a tonsillar abscess broken by gentle massage, and at first Olaf's powers were attributed to the fact that he had "good hands," but the case is of importance as carrying on the tradition of royal healing. After the reign of Henry II. historical evidence that his successors exercised the power is wanting until the reign of Edward I. In the meantime the title "Morbus Regius" had come to mean scrofula as well as jaundice, which alone it signified in classical times. Gilbertus Anglicus, Bernard of Gordon, and John of Gaddesden, who between the birth of the first and the death of the last cover the period 1160–1361, all use the term, and all say that kings have the power of curing it. It is notable that while Bernard puts the royal touch as superior, or at least equal, to surgery, Gaddesden, a little later, possibly owing to the practical English temperament, advises the possible remedies in the following order—medicines, royal touch, and if both fail surgery.

And so the record runs down the ages, with an occasional interruption. The last sovereign to touch for the evil was Queen Anne, but the service "At the Healing" appeared in the Prayer Book of George I., and the reader may trace in Dr. Crawfurd's pages the gradual changes which the ceremonial underwent. But though touching in England ceased with the last of the Stuarts, in France, where apparently the custom arose in Europe, Charles X. revived the whole office at his coronation in 1824. As a scholarly and careful record of a by-way of medicine, of a custom, too, which goes back in its inception to the earliest times, and is connected with some of the deepest feelings of human nature, the desire for health and faith in the supernatural, this book can be commended.

Trattato dei Neoplasmi Maligni, preceduto da uno Studio sulle Infezioni Chirurgiche in Generale. Volume Primo. Con 81 figure nel testo e una tavola a colori. Pp. xlvii. – 944. Di Professor D. B. RONCALI, Direttore del R. Istituto di Patologia speciale Chirurgica della R. Università di Padova. Torino: Unione Tipografico-Editrice Torinese. 1911.

IN no subject is the disparity between our actual knowledge of it and the enormous amount of work which has been expended on it so marked as in that of cancer. The present book, which brings together more information than any other we know upon this subject, underlines this statement. Its author, Professor D. B. Roncali, is Director of the Institute of Surgical Pathology in the University of Padua, and its production is a proof that the fire of research which burned there many centuries ago is still alight. It is a book in which 20 years of labour and experiment, combined with learning and insight, have all contributed to produce a result which, in our present knowledge, should be a stimulus to those working at its main subject, as well as a storehouse of information for them. There is one thing which may to some extent lessen the usefulness of this book, and that is the fact that its author is of opinion that there must be a specific parasitic cause of cancer. But we really know so little of the immediate cause of cancer that this ought not to stand in the way of a proper appreciation of work which is so comprehensive and wide. The author, by the way, disclaims the idea entirely that this is in any way the last word upon this difficult subject, knowing well that we have yet nothing like sufficient knowledge even to make a few generalisations on it. He appreciates the difficulties of divided work on cancer; he knows that the clinician has not the necessary time even to follow, and cannot have the necessary knowledge to enable him adequately to judge of the vertiginous movements of the biology of to-day. So he approaches the subject alike from the clinical, experimental, and pathological points of view; and the book is divided into lessons, in which the separate arguments can be treated with less rigidity than in formal chapters, making the whole very pleasant and easy to read. Those who have had to wade through the thousands of papers and books on this subject will appreciate the advantage of this. The author, unlike many modern writers on the same subject, has made much use of clinical observations. He is convinced of the principle, which ruled in medicine from Morgagni to Claude Bernard, that whatever the importance of an experimental discovery may be, it can never lower the supremacy of clinical observation; and he takes as motto the well-known words of Protagoras: Πάντων χρημάτων ἄνθρωπον μέτρον εἶναι. He first uses observations, and then illuminates the facts observed by experiment, which seems to be the logical course. We are apt to forget that before the experiments in the laboratory of to-day were a thousand years of clinical observation.

The whole work is to consist of six parts, of which three constitute the present volume. These are: 1. Conceptions of inflammation. 2. Classification of surgical infections. 3. Anatomical, pathological, and clinical criteria by means of which malignant new growths ought to be separated from benign, and to be considered as infections, or inflammations *sui generis*. The analogies between inflammatory processes and cancer, and the looking on cancer as a specific reaction are, of course, not new. The same views were suggested by Plimmer many years ago, but they are here worked out with such detail and instance that they assume quite different proportions and become thoroughly suggestive. In the first part the limits of inflammatory processes are established. In the second part the general characters of surgical infections are described. For purposes of description these are divided as follows: those in which the effect is entirely toxic (tetanus); those which are toxic and in which the parasite also plays an active part (septicæmia, pyæmia); suppurative (abscess, phlegmon); erythematous (erysipelas); pseudo-membranous (hospital gangrene); those in which the parasite exerts its pathogenic power on particular cells—e.g., in rabies on the pyramidal cells, in osteomalacia on the bone cells, in coccidiosis on the epithelial cells of liver, intestine, and skin; the granulomata (tubercle, leprosy, &c.); and malignant neoplasms, epithelioma, sarcoma, &c). These two parts are to be looked upon as a preparatory study to the third part, which treats of malignant new growths in general and in particular, and the author here brings a large amount of anatomical and clinical evidence together to support his view that the cause of cancer is either a parasite, or something which acts on the cell as a parasite. He makes a most minute study of the biology, morphology, and degenerative processes of neoplastic cells, and of carcinomatous foci, in which they are compared biologically, morphologically, and in regard to degenerations with the cells and foci of various infective processes, particularly with the granulomata, whether spontaneous or experimentally produced; and his conclusion is identical with that of Menetrier, who, notwithstanding his opposition to the parasitic view of cancer, does not hesitate to say that "all the morphological alterations of the cancer cell are to be met with in cells altered by inflammatory processes, with this difference, that in malignant growths of connective tissue the acute and subacute inflammatory processes will furnish the more exact type of comparison, whereas in epithelial cancer,

the type of comparison will be found in chronic inflammatory processes." The study of the manner of the formation of metastases has added new arguments for the demonstration of the intimate bond between malignant neoplasms and inflammatory processes, and likewise has made clear the mode by which carcinomatous diffusion in the body of the host is to be differentiated from that of any other infective process, and helps to explain why cancer should be called an infection *sui generis*. Following his rule of taking the mass of anatomical and clinical facts before the experimental, the author shows that in new growths the occurrence of metastases can take place in two ways: either by specificity, or by cellular infection. In the first class are those metastases which histologically reproduce exactly the primitive growth; this is the commoner means of the diffusion of cancer and belongs exclusively to cancer. In the second class we have those metastases which are histologically quite different from the original growth, and these are exceptional forms of metastases, their genetic mechanism being common to those of the granulomatous processes; for in this case the neoplastic cell acts as if it were a parasite, exciting the tissues with which it comes in contact to proliferation, not first multiplying itself. The author thinks that the clinical and experimental facts justify the belief that, in this second contingency, the neoplastic cell is able to provoke a metastasis by exercising an action which is directly infective by means of its protoplasm, and an indirect action by means of parasites which may be contained in it.

The next part of the volume discusses the complex series of phenomena which constitute the cancerous cachexia, or toxæmia, caused by probably many poisonous substances which are eliminated by the cancerous foci and the metastases, by means of which the cellular elements of various organs become deteriorated in structure and perverted in function. The differences in the effects according to the situation of the cancer are very well described—e.g., in a gland with only internal secretion, and in one with both internal and external secretion; the histological and functional alterations of the various organs are clearly stated and arranged; the anæmia, wasting, fever, œdema, and the various psychoses are discussed at length, and are compared with the consecutive phenomena of chronic infective diseases, such as tubercle or syphilis; and the author concludes that cancerous cachexia or toxæmia in its anatomical, pathological, and clinical complex has in it nothing specifically characteristic, nothing which cannot be found in the general intoxications consecutive to various infective processes, especially the granulomata. The author insists upon the intimate relationship of the cancerous processes with infections in general and with the granulomata in particular, and with their absolute separation from those of benign growths. As a natural corollary there follows a complete study of the histological texture of the separate malignant growths. The comparisons between the early stages of cancer, in which the transition from a normal cell to a cancer cell takes place, and the alterations in inflammatory tissues during the progress from an acute inflammation to a chronic one, are extremely well worked out and are full of suggestiveness. To most readers the pathological and histological studies of the various species of new growths will appeal; they are clear and well done, and especially good is the section upon complex tumours, a subject which is generally very confused and confusing.

The whole of this part of the book forms an excellent treatise on oncology, in which there is an attempt at both synthesis and reorganisation, according as the histogenesis is able to be interpreted respectively by the doctrine of blastomeres of Bonnet and Marchand, by that of cellular metaplasia, or by the author's "ovo-spermoblastic" doctrine. The classification is essentially embryonic, and the carcinomata, in the broad sense, are divided into four subdivisions: (1) connective tissue tumours (sarcoma, endothelioma, perithelioma, and lymphoma); (2) epitheliomata (epithelioma of the various kinds, neuro-epithelioma—subdivided again into glioma and its varieties, and gliopyramidoma); (3) complex tumours (divided into blastomeric, metaplastic, and ovo-spermoblastic tumours); (4) placentomata (divided into chorion-epithelioma, deciduoma, and chorion-deciduoma). After a description, both general and particular, of the clinical characters and histological texture of all the sarcomata; of the epitheliomata proper and the neuro-epitheliomata; of the cellular metaplasia connected with the mixed sarcomatous tumours; and of the laws which regulate the constant relation between the degrees of recidivity, anaplasia, atypicality, and malignity, the author gives a very careful clinical, histogenetic, and anatomical study of the mixed tumours and the placentomata, which brings the volume to a close. The complex tumours are divided into acquired and congenital, and these last again into malignant and benign. The many doctrines and hypotheses current with regard to their histogenesis are discussed with great fairness and skill. The author's division is again an embryological one. He concludes from a critical examination of the whole question that the congenital complex neoplasms, both malignant and benign, can be explained by the blastomere theory of Bonnet and Marchand; that the acquired neoplasms which develop in the glandular organs and viscera (breast, parotid, submaxillary gland, uterus, brain, &c.) can be explained by the metaplastic theory; and, finally, that those complex neoplasms which start in the ovary and testicle (solid or cystic embryomata) are explainable histogenetically by his own ovo-spermoblastic theory, which rests on the work of Boveri, Carazzi, and Wilson on predetermined germinal localisation.

Although the author's researches have led him on broad lines towards the parasitic theory of the origin of cancer, the criticism throughout the book is of the best kind, impartial and unirritating, and he always keeps in mind the fact that we really know nothing certain on this vexed question, and he, at any rate, "dares stamp nothing false where he finds nothing sure." The book is well printed and well illustrated, and, apart from any particular views, is encyclopædic upon the subjects of "Inflammation and Cancer," which is its second title.

Lehrbuch der Kinderheilkunde. Edited by E. FEER, Director of the University Children's Clinic in Heidelberg. With 2 coloured plates and 160 illustrations. Jena: Gustav Fischer. 1911. Pp. 734. Price M.11.50, unbound.

THIS volume is practically a supplement—a very large one, it is true—to Krehl-Mering's Text-book of General Medicine. The contributors, each in his own particular domain, are all men who have made pædiatric history in Germany. The editor in his preface plaintively remarks that the branch of medicine covered by this volume has now attained to such a degree of specialisation that no one man can be expected to do justice to all its ramifications. It is quite certain that each of the 11 sections of which this work consists has been written by a master of his subject. It is almost surprising that, under such conditions, the bulk of the volume has been kept within the relatively modest compass of some 700 pages. Without qualification this statement perhaps hardly does justice to the moderation and restraint of the company of authors, for a page of a normal German scientific text-book is often an ocean of print. This book is, however, printed in large bold type, is well paragraphed, and freely illustrated, and hence, as has been

said, is a comparatively small book. There is little in the general arrangement of its contents to differentiate this volume from many others on the same subject which have been reviewed during the last few years in THE LANCET. There is, however, greater uniformity of method between one chapter and another than is usual in composite works.

Professor Pfaundler, who appears to have unlimited capacities for literary productiveness, is responsible for a very good chapter on certain constitutional and blood diseases. The sections on the inflammatory, or exudative, diathesis, the status thymico-lymphaticus, neuro-arthritism, Mongolian idiocy (Mongolismus), are certainly worthy of careful attention. The diseases of the respiratory system are ably dealt with by Professor von Pirquet; syphilis is dealt with by Professor Moro; while Professor Feer himself has contributed a number of admirable chapters. Chief among them is that on the acute infective diseases, which, by the way, includes acute polyarthritic rheumatism, the latter occupying some five pages. To this chapter one accessory page is attached which deals with chronic rheumatism—probably a somewhat disproportionate distribution of favours according to English ideas.

The chapter in this volume, however, which is likely to prove of greatest interest to English readers is that by Professor Finkelstein and his colleague Dr. Ludvig F. Meyer, on the diseases of the digestive organs. The part of this chapter, and it is much the largest part, which is concerned with disturbances of nutrition in infants is quite revolutionary in character and arrangement. As is well known, Professor Finkelstein attributes most of the troubles of infancy to food causes; and he discounts almost to the vanishing point the part played by bacteria in the production of gastro-intestinal troubles. Practically the same views have been maintained by English writers, but Professor Finkelstein has had almost unrivalled opportunities in Berlin for establishing by the clinical test the presumptive truth of many of his main theses. Many authors, in dealing with disturbances of digestion and nutrition in infants, separate these groups into independent disorders of the stomach, intestines, liver, pancreas, and so on, but not so Professor Finkelstein, who groups all the symptoms attributable to disturbances of digestion or nutrition under one heading. In so many words, he says the organism has a certain degree of tolerance for food—what we should call powers of physiological utilisation; when these are abused or over-reached we get certain reactions or disturbances which are similar in kind but different in degree, and according to the degree he classifies them as follows: 1. Mild disturbances of function: (*a*) dislocation of equilibrium (Bilanzstörung); (*b*) dyspepsia. 2. Severe forms with organic changes: (*a*) decomposition; (*b*) intoxication. The disturbance in its fourth degree of severity (intoxication) is practically the same as that which often passes under the somewhat unscientific name of marasmus or the more scientific name of athrepsia. So far as food is concerned Professor Finkelstein incriminates all elements—proteins, carbohydrates, fats, and even whey itself; but it is to some undetermined element in the latter that he holds chiefly responsible for the great majority of the troubles. His treatment is simplicity itself—the withholding of food, the giving of mild diffusible stimulants such as weak tea or broths, and the subsequent return to a modified milk diet in which the fat percentage is kept low and the carbohydrates are not exclusively of the milk-sugar variety.

Professor Feer's text-book can be commended to the notice of English readers. And but for the fact that there is already a plethora of modern works in English of almost equally high standard, we should expect to see an English translation.

A Laboratory Text-book of Embryology. By CHARLES SEDGWICK MINOT, LL.D., D.Sc., James Stillman Professor of Comparative Anatomy in the Harvard Medical School. Second edition, revised, with 262 illustrations, chiefly original. London: J. and A. Churchill. 1911. Pp. 402. Price 16*s.* net.

IT is easy to understand why this excellent work is dedicated to Henry Pickering Bowditch, who died only a short time ago. Bowditch was one of the pioneers of physiology in America, and was one of the early pupils of Ludwig in Leipsic. Minot was one of Bowditch's many pupils, and later he also began his physiological studies in Leipsic. On returning to Harvard Minot's bent soon showed itself, and his name is now inscribed large amongst embryologists who take a wide and comprehensive view of the importance and relations of this attractive subject. The work is designed primarily for the use of students taking a practical course in embryology and aims at directing the student's attention to actual original observations to be made by himself. This is the second edition, and it has been so extensively revised that it may be described as almost a new book.

The chapters are of very unequal length. The first one deals with general considerations, and it is impressed on the student that the embryo illustrates with particular clearness the fundamental principles of morphology. To a medical student embryology gives the clue to the intelligent comprehension of the anatomy of the adult, while it throws a vast light on pathology, the problems of malformation and monstrosities, and also upon the whole question of pathological changes in the tissues. In the first 30 pages a terse, vivid, and living description is given of such subjects as the segmented animals and metamerism, of the vertebrate type of structure with its six more important and six less important characteristics, and then each of these twelve is successively passed in review. This is followed by a rapid survey of the principal modifications of the vertebrate type, which brings us to the word "anlage," which has obviously come to stay, and which the author defines as "the first accumulation of cells in the developing embryo recognisable as the commencement of a structure, organ, or part." Then follows a short account or summary of such subjects as cytomorphosis, larval and embryonic types, germ layers, relations of surface to mass, and this leads to a study of projections, invaginations, and then to a classification of glands, the law of unequal growth, germ cells, sex, the theory of heredity, i.e., the theory of germinal continuity which we owe to Moritz Nussbaum—the only theory which to the author seems tenable at the present time. The chapter winds up with a short account of the law of recapitulation and the arrest of development.

The second chapter is necessarily a long one (p. 33–117) as it deals in detail with the early development of mammals, beginning with spermatozoa, ovulation, ovum and its maturation, impregnation, segmentation, and blastodermic vesicle—all of which is set forth much as in other books—and proceeding step by step to the formation of the layers and the origin of the mesoderm. Each part is then shortly described, beginning with the primitive axis, notochord, and its fate, archenteron, the digestive canal, the nervous system and the sense organs, the origin and destiny of somatopleure and splanchnopleure, and then the development of organs, finally ending with the allantois, trophoderm, umbilical cord, the chorion, and amnion. These two chapters occupy about one-third of the volume. About 30 pages (Chapter III.) are given to the human embryo. It is admitted that our knowledge of its early stages is very imperfect. As to classification of the early stages, 11 such stages are postulated, the last of these in embryos of about

10 mm. long. Each of these stages is then described in detail so far as they are known in certain of the primates, but more particularly in man. Some of the illustrations are taken from the well-known work of Coste. Embryos of various ages are carefully figured, drawn accurately to scale. Chapter IV. is short (pp. 160–173), and deals with the segmentation of the ovum and of the blastodermic vesicle in mammals. For laboratory work on this subject two animals especially have been studied—viz., white mice and rabbits. The work of Sobotta and of Kirkham on white mice forms the basis of our knowledge of these early stages in mammals. Careful details are given of the period of heat. In the mouse this occurs 21 days after littering. The ovum of the mouse measures only 80μ, and is the smallest known mammalian ovum. That of the cat measures 200 , of the rabbit 161 .

Chapter V. (pp. 174–218) is devoted to the classic subject "Young Chick Embryos." As in other text-books, details are given of how to obtain, to remove, and to preserve the embryos, and how to cut serial sections. The staining processes used are given more fully in the last chapter. Careful descriptions and excellent figures of chick embryos with from eight segments onwards are given with a great wealth of detail. The study of pig embryos occupies pp. 219–330, and is particularly full and painstaking. Pigs of 7·5 mm. are first selected for the study of outward form, and so on with those of greater age and length; then their general anatomy is described and copiously illustrated. Some of the illustrations are singularly artistic, while others represent wax reconstructions. Then follow elaborate studies of sections, serial and otherwise, of the embryo as a whole or of its individual parts. The largest pig embryo studied is 24 mm. The last chapter but one (pp 339–.376) is devoted to the study of the uterus and the fœtal appendages of man. A wax reconstruction of a uterine gland of a virgin of 18 years gives an idea of the very great complexity of such glands—a fact hardly revealed by sections shown in the ordinary text-books. The last chapter is devoted to methods, much on the lines of those commonly found in text-books of histology.

The work is one that can only receive the highest commendation. Anyone who has worked through such a course as is here laid down, and, as we gather, is actually carried out in Harvard, will have received a training both in original observation and in technique such as but rarely falls to the lot of medical students in this country. It would be interesting to know what time is devoted to such a course. Professor Minot is to be congratulated most warmly on the success, efficiency, thoroughness, and stimulating character of his work.

Medical Revolution: A Plea for National Preservation of Health based upon the Natural Interpretation of Disease. By SYDNEY W. MACILWAINE, M.R.C.S. Eng., L.R.C.P. Lond. (retired). London: King and Son. 1911. Pp. 162. Price 2*s.* 6*d.* net.

THE author of this small book is satisfied that medicine is hampered by a false interpretation of disease, and he sets before us what he considers the only true gospel. He is, it would seem, a little doubtful of the salvation of his *confrères*, for he addresses himself primarily to the "intelligent layman," and his book is a sign of the times, as showing a general appreciation of the difficulties produced in the practice of medicine by the rapid developments of modern science. This, however, is not quite how the author would describe his own able reflections.

His argument falls into two parts—first, a destructive criticism of things as they are; second, a constructive account of things as they ought to be. The second part, however, comes first in the book and the first second, while towards the end the constructive side is brought forward again. The arrangement is less confusing than might be expected, and for the most part the author's views, though strong, are expressed with admirable restraint and moderation; though now and again, as when he puts up a specialist to hit at, or describes Virchow's part in the development of medicine, his masseters tighten in a way that hardly suggests the philosophic spirit. Briefly summarised, his thesis runs as follows: All diseases are the effects of natural causes; the causes fall within the study of medical science, the effects and their prevention within the art of medical practice. Every "true" disease is, by definition, a mental conception drawn from a number of cases showing determinate and similar causation. These true diseases are separated into two groups according to whether the cause lies in the patient's environment or is constitutional. But it is the habit of the present day, says the author, to jumble together several diseases in one, thus creating "spurious" diseases. He takes Bright's disease, for example, as an effect of several different causes (scarlet fever, influenza, gout, lead-poisoning). The symptoms are not of determinate and similar causation, and therefore when the medical man diagnoses Bright's disease he makes an illusory diagnosis, preventive measures become impossible, and medicine is defrauded of its legitimate aim.

So far we can accompany the author. It is true that some of our "diseases" are only groups of symptoms. We are working to remove this reproach. But when he comes to explain why we of the medical profession are illusory diagnosers of spurious diseases he shows a bias that makes it difficult to go forward with him. Morbid anatomy, according to the author, has been the profession's undoing, and Virchow is the evil spirit who enmeshed it. According to the author, when Virchow exposed the ancient sham of humoral pathology he set in its place the equally fallacious doctrine of cellular pathology based on the dogma, "Every chronic disease is rooted in an organ." And Mr. Macilwaine feels so strongly against morbid anatomy that he will see nothing good in it at all. He tells his readers that outside the narrow circle of orthodox "pure physicians" Virchow's pathology is as completely ignored as the humoral pathology, and that the pathologist of to-day uses it merely to cloak his ignorance. Virchow's dogma, he holds, has no foundation in fact, and is not one whit less artificial than the ancient humoral pathology. Locomotor ataxy, for instance, is not a disease, inasmuch as its lesions can be produced by different toxic agents; fatty degeneration of the heart and myxœdema the same. These and many others for Mr. Macilwaine are spurious diseases, and Virchow "could not have done a greater disservice to medicine" than in setting up morbid anatomy as its guiding science. The statements as to the illogicality of our nomenclature of diseases are sound, but to assail morbid anatomy in the terms which the author employs, to see nothing good that has come out of it, to deny it a leg to stand on, bespeaks either a biassed mind or imperfect knowledge. How far does morbid anatomy deserve these strictures? Had it done nothing more than establish the facts that one of the effects of the tabetic toxins is to be found in the posterior columns of the cord, that fatty degeneration of the heart does exist and often goes with phosphorus poisoning, and that atrophy of the thyroid gland is associated with myxœdema, it would have earned the gratitude of the medical profession. As a matter of fact, from the apparently barren subject of post-mortem observation was generated, in due time and in large measure, the science of bacteriology and parasitology, which has boundlessly increased our knowledge of causation and our practice of prevention.

The author, we consider, has taken up an untenable position, even while he makes out an interesting case for his system of reform and is able to apply it in a practical way. Few who read this book will go back to their patients without feeling that their mental attitude towards disease has undergone some change, and for this reason we thank Mr Macilwaine for the courage and industry which have led him to write his book. We also endorse very heartily the view that the prevention of medicine would be well served by more regular and anxious inquiry into the heredity and environment of our patients than the present conditions of medical practice permit.

Tumours, Innocent and Malignant: their Clinical Characters and Appropriate Treatment. By J. BLAND-SUTTON, F.R.C.S. Eng., Surgeon to, and Member of the Cancer Investigation Committee of, the Middlesex Hospital. With 360 illustrations. Fifth edition. London, New York, Toronto, and Melbourne: Cassell and Co., Limited. 1911. Pp. 686. Price 21*s.* net.

FROM its first appearance Bland-Sutton's "Tumours" was accorded a place amongst the highest of the works on new growths, whether in English or in any other language, and that position has been fully maintained with every subsequent issue of the work. We have read it in different stages of its development, and, as our readers know, have consistently found it good. For two things this book is chiefly noticeable—the originality of the treatment of the subject, and the wealth of illustration derived from cases of neoplasms, not only in human beings, but also in the lower animals. No one can even glance through this volume without being struck with these characteristics. One other point deserves mention. The carefully chosen bibliography which follows every chapter is remarkable not so much for the number of the references as for their rigid selection. The etiology of carcinoma is discussed in a very critical but judicious manner, and we are interested to see that the author is inclined to believe that malignant disease is due to "a micro-parasite which stimulates the normal cells to multiply and produce cancer." There are still many debatable points in connexion with tumours, and there is room yet for two opinions on many of these; and though we may differ from the author on some of these, all will allow that this work is a trustworthy treatise for the student and a monument of British pathology.

Traité Pratique de Pathologie Exotique, Clinique et Thérapeutique. Publié en Fascicules sous la Direction de MM. CH. GRALL et A. CLARAC, Médecins Inspecteurs des Troupes Coloniales. Vol. V.: Intoxications et Empoisonnements; Béribéri. Par MM. HÉBRARD, GAIDE, CLARAC, LASNET, BOYÉ. Avec 124 figures. Paris: J. B. Baillière et Fils. 1911. Pp. 452. Price, paper, 12 fr.; boards, 13.50 fr.

THIS, the fifth volume of the above treatise, opens with the subject of beri-beri. This disease, concerning the etiology of which there have been so many varied hypotheses offered, is a notable one, inasmuch as it affects so adversely the efforts at colonisation of the European immigrants into tropical climates. Originally of Asiatic origin, it has successively invaded various tropical regions, and now to-day it is found to influence generally the colonisation of warm countries by Europeans. Dr. Hébrard, the author of the article, first tells us of its origin and diffusion. The original birthplace of the disease was in Asia, where it appeared in China, Japan, Indo-China, Burma, India, and the Malay Peninsula. The disease ravaged the Japanese army in the late Russo-Japanese war. More recently it has attacked New Caledonia; then Senegal, the Belgian Congo, and other places in Africa; next we find Brazil, Guiana, and the Antilles attacked; so that it affects a large portion of the intertropical globe. The author makes four classes of the affection—the acute, the subacute, the incomplete, and the chronic. The clinical characteristics of these various manifestations are succinctly and clearly portrayed, first as a whole for each of the classes, and they are then individually analysed. In the differential diagnosis the distinction from Bright's disease, chronic alcoholism, ankylostomiasis, rheumatism, malarial cachexia, tabes, the Aran-Duchenne type of progressive muscular atrophy, the toxic polyneuritis of arsenical poisoning and diphtheria, and lastly, epidemic dropsy, is detailed. The author, with regard to the last-named disease, however, does not mention the researches of Bentley, which certainly tend to prove its identity with beri-beri. The pathological anatomy is given, and then its rate of mortality. This in some epidemics has been as high as 85 per cent.

The etiology is next discussed. The author at once gives his opinion that the subjects of the malady are those people who eat rice as the basis of their food-supply. He then proceeds to show that white rice is the culpable agent. This rice, being decorticated, is exposed in a greater degree to contamination; whereas the red rice, not having lost its cortex, offers greater resistance to any pathogenic microbe, and has less chance of becoming contaminated. All this has been made very familiar to readers of THE LANCET, mainly by the excellent work of Dr. Henry Fraser and Dr. A. T. Stanton. But the French authors consider that white rice alone will not produce the malady. In Asia, for instance, the great majority of rice eaters are immune to this disease. Hence there must be some other factor apart from the quality of the rice, and the author opines finally that this food acts as the vehicle most favoured by the pathogenic agent, which is a toxin of some sort. But the actual microbe responsible for this toxin has not yet been indubitably shown. The article concludes with the treatment of beri-beri. As regards prophylaxis, the introduction of the infectious agent must be avoided, by attention especially to the quality of the rice, and by making all the environment of the *personnel* as sanitary as possible.

Amongst the other articles included in this volume are those concerning opium poisoning, by Dr. Gaide; hashish poisoning and poisoning due to fish and snakes, by Dr. Clarac, who also writes on the effects of quinine on certain individuals. The volume fully comes up to the reputation established by its predecessors.

Carbonic Acid Snow as a Therapeutic Agent in the Treatment of Diseases of the Skin. By R. CRANSTON LOW, M.B. Edin., F.R.C.P. Edin., Assistant Physician to the Skin Department, Royal Infirmary, Edinburgh. London and Edinburgh: William Green and Sons. 1911. Pp. 117. Price 5*s.* net.

ALTHOUGH the employment of carbon dioxide snow is comparatively recent, it is now widely used, and with great success, in a large number of cutaneous conditions. Many articles have appeared describing the uses and the results obtained by the use of carbon dioxide snow, but this is, we believe, the first book dealing wholly with this method of treatment. When liquid carbon dioxide is allowed to evaporate rapidly some of it becomes solidified by the rapid abstraction of heat, and this solid carbon dioxide has a temperature equal to − 79° C., so that if applied firmly to the skin immediate freezing of the tissues results. For turning the liquid into the solid carbon dioxide many forms of apparatus are made, most of which are convenient, but they are not essential, for a piece of wash-leather or even a towel is quite sufficient. In this work several forms of apparatus are described and their merits are compared. Then the effects

of the snow on the skin and the effect of varying the duration are referred to. A chapter is devoted to the microscopic changes induced, and some illustrations show the alterations that the tissues undergo. The therapeutic uses of the snow form the most important part of the subject, and Dr. Low speaks with a reasonable enthusiasm of the results obtained.

Bericht über die Ergebnisse der Konjunktivalreaktion mit Tuberkulin, sowie über die lokalen Tuberkulinreaktionen bei Tieren, speziell beim Rinde. (Report on the Results of the Conjunctival Reaction with Tuberculin, especially the Local Tuberculin Reaction in Cattle.) Von Dr. A. WOLFF-EISNER. Jena: Gustav Fischer. 1911. Pp. 49. Price M.1.20.

Dr. Wolff-Eisner's name is now well known in relation to the methods for the diagnosis of tuberculosis. The conjunctival reaction is more closely associated in England with the name of Dr. Calmette, although Dr. Wolff-Eisner must be accorded the priority of one month in publishing the method. Some discredit has fallen upon it as applied to man owing to results that have occasionally attended its use, and to the frequency with which a positive result is obtained in apparently non-tuberculous subjects. Dr. Wolff-Eisner in this paper fights strenuously for the retention of the test, more particularly in the domain of hygiene, for the diagnosis of tuberculosis in cattle. Writing of the conjunctival reaction in man, he states that whilst in healthy persons over 20 years of age the cutaneous reaction is positive in 50–80 per cent. of cases, only 5–10 per cent. show a positive result with the conjunctival reaction. Moreover, a considerable number of the latter cases show signs of tuberculosis in the course of one or two years. If both reactions are positive, active tuberculosis is present. If only the cutaneous reaction is positive the tuberculous affection is relatively inactive.

The paper is concerned principally with a research on the value into the conjunctival reaction in oxen. A 40–50 per cent. tuberculin is used in place of the 1–4 per cent. solution used in man, and the experimental results tabulated in the paper show the high value which is to be attached to the reaction as a means of eliminating tuberculous cattle which might otherwise be used for food.

Theory and Practice of Thyroid Therapy. By HERBERT EWAN WALLER, M.R.C.S.Eng., L.R.C.P. Lond., Honorary Anæsthetist, Birmingham Dental Hospital; Medical Officer, Balsall Heath Provident Dispensary. London: John Bale, Sons, and Danielsson. Pp. 154. Price 5*s.*

Mr. Waller first discusses the function of the thyroid gland, which enables the body to make use of calcium salts. He applies this principle to various conditions. He is of opinion that rickets in its worst form, starting as it does in the earliest months of life, is primarily caused by depriving the infant of the benefit of maternal thyroid activity, the infant's own thyroid secretion being invariably unequal to its requirements at birth. He supports this view with the statement that "the protective influence of breast-feeding against rickets has been placed beyond dispute." He applies the same arguments to dental caries, and maintains that this condition also is largely due to artificial feeding, the infant being thereby deprived of the benefits of maternal thyroid activity. Thyroid insufficiency, he points out, may be brought about in another way—namely, by the deprivation of calcium salts. Mr. Waller believes that calcium salts are the normal stimulus to thyroid metabolism, and without this stimulus secretion may become deficient. He considers that this fact explains the beneficial action of lime salts as a remedy in deficient nutrition. Considerable space is devoted to a consideration of the relation of iodine and arsenic to the thyroid activity. The reasoning adopted in these matters is rather involved and difficult to follow, and the conclusions arrived at are vague. Nevertheless, the subject would seem to be a promising one for investigation, and doubtless Mr. Waller has done good service in drawing prominent attention to it.

The whole book is certainly worthy of perusal. Mr. Waller has employed thyroid medication in a variety of conditions, and his remarks are suggestive. Inquiry founded on the lines which he has followed may lead to valuable results: more cannot yet be said.

Les Maladies de la Cinquantaine (Diseases of the Fifties). Tome I., L'Artériosclérose; Tome II., Clinique du Cœur; Tome III., Le Diabète; Tome IV., Les Albuminuries. Par Dr. ARTHUR LECLERCQ, Lauréat de l'Académie de Médecine. Paris: Octave Doin et Fils. 1908–1911. Vol. I., pp. 335; Vol. II., pp. 357; Vol. III., pp. 438; Vol. IV., pp. 264. Price, Vol. I., II., and III., 6 fr. per volume; Vol. IV., 5 fr.

DURING the decade of life comprised by the "fifties" degenerative processes, metabolic disturbances, and cardiovascular changes are liable to become manifest, particularly in those in whom hereditary tendencies have been helped by strain, toxic conditions, dietetic errors, and misuse of alcohol. Most of these conditions are insidious in their origin, slow and progressive in course, and too often come for treatment when advanced and irreparable. The hygiene and management of this period of life are therefore important, and the recognition of early stages of these conditions may be the means of prolonging life and of delaying or avoiding the usual sequels. Dr. Arthur Leclercq has subjected the more important of these diseases to a careful and exhaustive analysis, and has reviewed their causation, pathogenesis, and treatment in the four volumes before us. His views as to their essential nature and development are somewhat original and are given at considerable length and with no little repetition. His theories are interesting, but require confirmation. His observations on treatment are full and helpful, as he discusses the various procedures and drugs which have been recommended.

The first volume is devoted to arterio-sclerosis. This condition is regarded as a reaction on the part of the arterial system to visceral changes, particularly in the liver and kidneys. The liver, as a consequence of disturbed metabolism induced by alimentary errors and by abuse of alcohol, is first stimulated to an excessive activity of its functions—a condition followed by a diminution preparing the way for the so-called arthritic manifestations, such as gout, gravel, obesity, and diabetes. These are regarded as defensive mechanisms rather than as morbid states, their object being to protect the organism from waste products which would lead to sclerosis of the organs. Dr. Leclercq would therefore replace the term arthritism, so dear to French writers, by hepatism. Other organs, notably the kidneys, share in the sequence of hyperfunction and diminished function. The diminished activity is in all cases associated with degeneration of the parenchyma and sclerosis of the supporting tissue. In the case of the kidney, these changes react upon the blood-vessels, which in turn show hyperfunction and then degeneration with fibrosis, constituting the condition of arterio-sclerosis. Other conditions simulating this state of the vessels—e.g., the sequels of infective arteritis from any cause such as syphilis—are differentiated as false or atypical arterio-sclerosis. True arterio-sclerosis is thus regarded as a viscero-arterio-sclerosis, its only cause being "hepatism," its only origin alimentary errors, its only adjuvant alcohol.

The second volume deals with diseases of the heart, classified according to the disturbance of rhythm produced.

The rhythms are described as eusystole, comprising the normal; dyssystole and asystole, the abnormal ones found in disease. These conditions are subdivided into various groups and examined in detail. The pathological relations, clinical characters, and treatment of each one are discussed. The classification is so minute as to be tedious and confusing.

The third volume, which has been "crowned" by the Academy of Medicine with the Alvarenga prize, is devoted to diabetes and exophthalmic goitre. These two diseases are regarded by Dr. Leclercq as strictly analogous in nature and pathogeny. They are described as being the result of a primary "dysfunction," followed by dystrophy of the entire organism, and especially of the nervous and neuro-glandular systems. The primary defect is regarded as occurring in the bulbar region, and diabetes is considered as a disturbance of the functional interrelations of the liver with other glands, notably the pancreas and thyroid; exophthalmic goitre as an alteration of the synergic action of the thyroid gland with other structures—viz., the ovary, hypophysis, and suprarenal. These highly speculative and theoretical views are developed at considerable length and are applied to considerations of treatment as well as of pathogeny.

The fourth volume contains an analysis of the various conditions giving rise to albuminuria, and is not restricted to a consideration of those occurring during the fifth decade. Here, again, the classification is a very minute one, and Dr. Leclercq's own views are given in regard to some forms of nephritis and to uræmia. Considerations of treatment are fully discussed and in a practical manner.

Modern Methods of Water Purification. By JOHN DON, F.I.C., A.M.I.Mech.E., and JOHN CHISHOLM, A.M.I. Mech.E. London: Edward Arnold. 1911. Pp. 368. Price 15*s.* net.

THIS work is a valuable addition to the literature of the important subject of water purification. The authors have made a punctilious study of the different methods of water purification adopted in this country, in America, and in various continental countries, and these methods are carefully criticised. A concise and complete bibliography of books and papers on water purification is given in a useful appendix.

A feature of this work is that the subject is treated not solely from the public health aspect, but that special attention is paid to the engineering aspect of the subject. A chapter is devoted to sources of water-supply and another to the storage of water, wherein full consideration is given to the important work done by Dr. A. C. Houston in this respect. The use of copper sulphate in restricting the growth of algæ in stored water is fully dealt with. Sand filtration and the scientific explanations of this important part of water purification are gone into in great detail. The information as to the management of sand filters will be of great value and assistance to the water engineer. A special chapter deals with the purification of water by ozone, and gives the details of the process. Mention is made of the process of the sterilisation of water by means of ultra-violet light.

The various processes of water softening and the apparatus necessary for this procedure are carefully and fully described. "The Testing of Water" occupies two chapters and the conclusions to be arrived at from the results of analyses are set out. A short account of the bacteriological examination of water is given, but we think that this method of investigation must always be left in the hands of a competent bacteriologist. The water engineer should not attempt any detailed examination of the bacteria present in drinking water, since the investigations necessary can be satisfactorily carried out only by an expert.

Everyone faced with the problems of water engineering should possess this valuable contribution to the subject, and the book should also prove of great value to the analyst and the sanitarian, who have to consider the important subject of water-supply.

Thérapeutique des Maladies Respiratoires et de la Tuberculose Pulmonaire. By Drs. E. HIRTZ, RIST, RIBADEAU-DUMAS, TUFFIER, J. MARTIN, and KUSS. Paris: J. B. Baillière et Fils. 1911. Pp. 713. Price F.14.

THIS volume forms the third number of the *Bibliothèque de Thérapeutique*. The first article is by Dr. E. Hirtz, physician to the Necker Hospital, on the treatment of broncho-pulmonary affections. He describes at length the treatment of bronchitis, broncho-pneumonia, bronchiectasis, emphysema, asthma, pneumonia, and other diseases of the lungs. The directions given are clear and concise, and numerous prescriptions are suggested which will be found of value in actual practice.

The treatment of diseases of the pleura is discussed by Dr. Rist and Dr. S. Ribadeau-Dumas. The operation for thoracentesis is minutely described, and especial attention is drawn to the indications for, and the technique of, injections into the pleura of sterilised gas or air. This procedure is suggested in those cases of pleural effusion in which the fluid rapidly recurs; the results are stated to be encouraging, but further experience is necessary before a definite conclusion can be arrived at. With the aid of numerous illustrations Dr. Tuffier and Dr. Martin describe the surgical treatment of affections of the respiratory organs, including tracheotomy, intubation, pneumotomy, and pneumectomy.

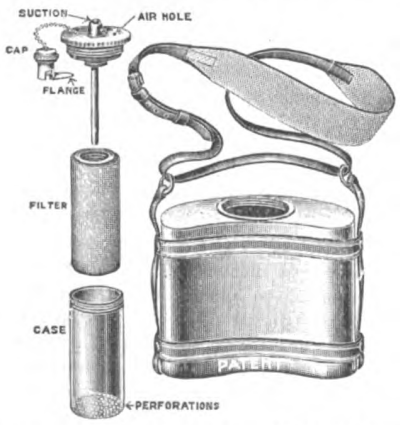
More than half the volume is occupied with a consideration of the treatment of tuberculosis, the article having been written by Dr. J. Kuss, physician to the Sanatorium at Agincourt. His remarks are characterised by the completeness and lucidity with which he describes the various therapeutic measures that have been introduced. He describes in detail the "open-air" treatment, and comments favourably on the usefulness of tuberculin if carried out with due precautions, but deprecates its use in inexperienced hands. He also refers to the artificial production of pneumothorax, and comes to the conclusion that in those cases in which extensive adhesions do not exist favourable results may be obtained.

We can speak in high terms of praise of this volume as being an excellent practical manual on the treatment of diseases of the lungs and pleura.

LIBRARY TABLE.

An Introduction to Experimental Psychology. (Cambridge Manuals of Science and Literature.) By CHARLES S. MYERS, M.D., Sc.D. Cantab., Lecturer in Experimental Psychology in the University of Cambridge. Cambridge: At the University Press. 1911. Pp. 156. Price 1*s.* net.—These little Manuals of Science are likely to fulfil a very useful purpose in the hands of those who use them in the right way. They are in no sense text-books, not even elementary ones, let alone "crams." They are intended to place before readers of ordinary intelligence and education, in terms that can be easily understood, a presentment of recent discoveries. The present volume aims to explain the methods of experimental psychology by describing typical themes of research therein, the subjects selected being touch, temperature and pain, colour vision, the Müller-Lyon illusion, experimenta æsthetics, memory, mental tests and their uses. This volume contains, by permission of Professor Ewald Hering and his

publishers, the instructive coloured diagrams representing the series of colour sensations, as given in the former's Grundzüge der Lehre vom Lichtsinn. The measurement of mental processes may arouse wonder even in those to whom scientific measurement of more concrete things is an ordinary task. Measurement is the first element of exactitude in most scientific studies, and its application to so elusive a subject as psychology is explained to the general reader in this little book.

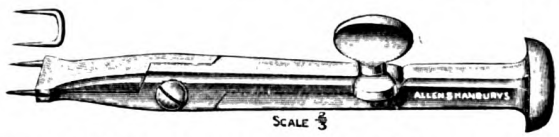


Queer Patients. By M. OSTON, M.D. Edinburgh: John Currie. Pp. 324. Price 3*s.* 6*d.* net.—This book contains 15 stories based on the more unusual incidents that have come in the author's way during his professional career. It is in a sense medical fiction, for while the main incidents, it is said, are all true, the circumstances and supposed personalities are fictitious. Some of the stories suggest valuable lessons to the practitioner, as, for instance, "A Mere Detail," in which an impending breach between husband and wife, owing to the latter's increasing irritability, is warded off through adopting the doctor's advice to change the wall paper in the dining room. "Lady Russel's Necklace" is a good, and by no means impossible, story. "The Letter D" is another good story illustrating the psycho-analytic method. We naturally referred to the Medical Register to see if Oston was the author's real name, but it is evidently an anagram. The book is decidedly readable.

Transactions of the Annual Conference of the National Association for the Prevention of Consumption and Other Forms of Tuberculosis at Caxton Hall, Westminster, July 19th–21st, 1911. London: Adlard and Son. 1911. Pp. 220. Price 2*s.* 6*d.* net.—The proceedings of this conference were reported in abstract in THE LANCET of July 29th, 1911. Those especially interested in the subject will do well to obtain the Transactions, in which all the papers read are reported at length.

New Inventions.

THE HAMILTON COMBINED CANTEEN AND FILTER.



THE illustration below shows the component parts of this well-thought-out arrangement, which provides the soldier with a store of water ready at hand and fit to drink. The canteen is a small curve-shaped cistern, in which is suspended a protected case enclosing a germ-proof filtering cylinder.

All parts are easily detachable and therefore cleaned, while the efficiency of the filtering material can be ensured by mechanical cleaning and by placing it in boiling water when that is available. An important feature consists in the provision made for drawing the water by suction. The soldier does not drink from it by tipping the apparatus to his lips as from an ordinary drinking utensil, but by drawing the water from a nipple at the top by suction. An air hole is provided by means of which air replaces the water withdrawn. There is thus nothing lost by spilling, and the canteen enables the soldier to drink in any position. Prone on the ground he does not need to raise his head. He is prevented from gulping the water, which is a source of danger in some circumstances; he must imbibe it at a moderate rate. Water filters through on its own account, but the flow of filtered water is, of course, increased by suction, which places a pressure upon the water in the canteen. The filter canteen is very light, the container being made of aluminium. It can easily be filled from any source, and the filtering medium is stated under severe bacteriological tests to be a barrier to disease organisms. We understand that the Hamilton combined canteen and filter may be obtained at the leading stores in London. There is also made a combined canvas water-bag and filter which are intended to allow as much extra water to be carried as possible. They are adapted to be carried round the necks of horses or camels, and appear to be made with due regard to the comfort and convenience of the carrier.

A COMBINED STAPLE HOLDER AND PUNCH.

IN performing Roux's operation for femoral hernia it is found that the staple cannot be easily controlled and fixed in position before being driven home. This is particularly noticeable in stout patients with a patulous femoral ring. The clamp punch here depicted renders the staple perfectly

manageable during the process of pinning the ligament and is then used as a punch, being removed when the staple has been driven home. The illustration clearly shows the detail of the instrument, which was made for me by Messrs. Allen and Hanburys, Limited, of 48, Wigmore-street, London, W.

C. M. PAGE, M.S. Lond., F.R.C.S. Eng.
St. Thomas's Hospital, S.E.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. Thomas Dwight, professor of anatomy in Harvard University.—Dr. H. C. Lutz, professor agrégé in the University of Paris.—Dr. Ostino, *privat-docent* of Laryngology and Otology in Turin.—Dr. Grandeau, professor of agriculture in the Conservatoire of Arts and Trades, Paris.—Dr. W. C. Phelps, professor of surgical anatomy in the Buffalo University.

LITERARY INTELLIGENCE.—The following new editions of well-known text-books are announced for publication by Messrs. Churchill:—"A Manual of Midwifery," by T. W. Eden, M.D., obstetric physician, Charing Cross Hospital. This book, in its third edition, has been thoroughly revised, 150 pages have been added to the text, and there are 60 new illustrations. "A Manual of Bacteriology," by R. Tanner Hewlett, M.D., professor of general pathology and bacteriology, King's College, London. This is the fourth edition of an admirable book for students. "A Handbook of Physics and Chemistry," by Herbert E. Corbin, B.Sc. Lond., and Archibald M. Stewart, B.Sc. Lond., headmaster of Alresford Grammar School. This also is a fourth edition, and now covers completely the extended syllabus of work required for the first examination of the Royal Colleges. "Quantitative Chemical Analysis, adapted for Use in the Laboratories of Colleges and Schools," by Frank Clowes, D.Sc. Lond., emeritus professor of chemistry in the University College, Nottingham, and J. Bernard Coleman, A.R.C. Sc. Dubl., head of the chemical department in the South-Western Polytechnic, Chelsea. This excellent book is now in its ninth edition.

THE LANCET.

LONDON: SATURDAY, OCTOBER 7, 1911.

The Medical Lord Mayor of London.

THE election of a medical man to the office of Chief Magistrate of the City of London is an event of considerable importance, as well as a proper source of gratification to the members of the new Lord Mayor's profession. It is fitting that the largest capital in the world, and the most wholesome, should have as its chief civic representative a member of that profession which has contributed so largely to its sanitary excellence, and consequently to its prosperity. If the way to be healthy, wealthy, and wise is not quite so simple as the words of the old jingle would have us believe, neither is that way so very complicated: it consists in studying the needful laws of life, and, having studied them, in sparing no reasonable expense to make the conduct of life possible according to those laws. This has been the spirit of our metropolitan administration now for many years, and we find in the appointment of a medical man to represent and to supervise the civic interests of the very heart of London an endorsement of that spirit.

Sir THOMAS CROSBY, who was elected Lord Mayor of London by the Liverymen of the City on Michaelmas Day, will enjoy the honour not only of being the first medical man who has occupied the chair, but also of being the oldest candidate for the position who has ever been elected. Born in Lincolnshire in 1830 he was educated at University College School and afterwards at University College, London, and subsequently became a student at St. Thomas's Hospital where he was later demonstrator of anatomy, and where he also enjoyed the advantage of having for one of his tutors the late Sir JOHN SIMON, the father of sanitary reform. After obtaining the Licentiateship of the Society of Apothecaries and the Membership of the Royal College of Surgeons of England in 1852 he commenced practice in the City; in 1860 he took the Fellowship of the College by examination, and in 1862 he graduated as Doctor of Medicine at the University of St. Andrews. His connexion with municipal affairs dates back to 1877. In that year he was elected a Common Councillor of the City of London, being Alderman for the Langbourne Ward. Thirty years later he served as Sheriff, and now despite his eight decades he becomes Chief Magistrate. The historical and professional ties between medicine and the City of London, to which this appointment forms a striking addition, are already close. The Royal College of Physicians of London, which dates from 1518, and whose foundation was purely medical from the beginning, for many years had its habitation under the shadow of St. Paul's. The Royal College of Surgeons of England grew out of letters-patent granted by EDWARD IV. to the "Freemen of the Mystery of Barbers of the City of London using the Mystery or Faculty of Surgery." The Society of Apothecaries of London, incorporated in 1617, is a City Livery Company, granting a registrable medical qualification. Many Lord Mayors of London by their vigorous advocacy of the Metropolitan Hospital Sunday Fund have advanced the cause of order in benevolence, which medical men know is so badly needed in medical charities. Many Mansion House Funds, again, have had their origin in catastrophes whose terror and tragedy have been largely medical. Again, to turn abruptly from grave to gay, the hospitality of the Mansion House to the medical profession has been conspicuously shown on such occasions as the dinner given by Sir WILLIAM MACARTHUR to the Seventh International Medical Congress which met in London under the presidency of Sir JAMES PAGET, and the dinner given by Sir HORATIO DAVIES "to meet the President of the Royal College of Physicians of London, the President of the Royal College of Surgeons of England, and other members of the medical profession."

The election of Sir THOMAS CROSBY to be Lord Mayor of London has, however, a broader lesson than any that is conveyed by remembering the association of the City with the profession of medicine. In all directions our calling has enlarged its boundaries, and in all directions it is seeking further to enlarge them. The presence of medical men in responsible municipal positions is a proof that this fact is obtaining public recognition, and this recognition will just now be most valuable to the public. Take one example only. The medical work of the Local Government Board, enormous as it is, is the growth of comparatively few years and assuredly will develop at an even greater rate than it has hitherto developed. But this sturdiness of growth, this irresistible tendency to annexation, has not been, and will not be, regarded complacently by all. Every extension of the work of State medicine means an invasion of provinces where private or, at any rate, non-sanitary interests have previously been paramount. Therefore, every extension is and must be regarded by certain sections of the population as an act of raiding, and may as a consequence provoke at the time a spirit of opposition to those entrusted with the duty of carrying it out. It is an invaluable thing that a medical man should have a voice in municipal counsels so that he may be present to explain sanitary proposals and remove from the public mind any apprehensions that they have been made for other than public purposes. The election of Sir THOMAS CROSBY as Lord Mayor of London emphasises in the most conspicuous manner possible the worth of medical counsel to a community.

Inter-Racial Problems.

WHILE not wishing to cavil at any of the soaring aspirations which have been set down as the objective of the first Universal Races Congress, nor to dispute the obvious good intention of a movement in support of which so many notable names have been enrolled, we feel bound to draw attention to certain dangers which we think have been passed over too lightly by speakers at that Congress, who dealt more especially with the sociological aspect of the racial question. This can be done conveniently now that

we have before us a report of the proceedings.[1] With the general objects of the Congress—viz., "a desire for a fuller understanding, the most friendly feelings, and a heartier coöperation between the white and coloured races of mankind"—we are in complete accord. Such a movement should bring credit to its originators. And it is no doubt doing them the barest justice to say that the advocates of this universal *rapprochement* between the nations are animated by a pure spirit of human benevolence. That the first congress of the kind should be held in London may be a coincidence, but it is quite in keeping with the view that the problems of racial intermixture fall finally to the Anglo-Saxon for solution. If there is one Power whose whole future is bound up in such solution it is ourselves. And because the interests at stake are so tremendous we must, in a political sense, walk warily, not sacrificing eternally to expediency, but certainly not following brightly imaginative ideals without due circumspection. Living in the future is often enough a harmless and an enjoyable form of recreation, but it is only a dweller in a fool's paradise who could suppose that mankind, of whatever race or colour, is ripe for changes so momentous as some of the speakers at the congress have been moved to suggest. We need not dwell on the probable political and economic effects on our modern civilisation of some of the proposals set out in this report; it is enough to refer only to the sociological side of the question.

Racial prejudice has existed always; the first dawn of civilisation saw its birth, and in many cases it has developed alongside of that civilisation as part and parcel of it. The attempt to preserve racial purity is natural and instinctive, and whatever may be said to the contrary by those who blindly advocate the total removal of those barriers, and who suggest cross-breeding as a means of solving the problem of racial antagonism, such an action, we affirm, would precipitate social disasters. It is true that the speakers at the Universal Races Congress, who dealt with the sociological side of inter-racial problems, did not, we believe, go so far as expressly to advocate indiscriminate miscegenation in support of their ideals, but some of the arguments brought forward do so, at least by implication. What is proposed is, in effect, that the black and yellow races of mankind should mingle with the white races under a universal charter of social, political, and economic equality. Whatever the future may have in store for us in this world the time for such a commingling has not yet arrived. The instinctive dread of the consequences of racial assimilation, which has made in the Western States of America miscegenation a worse offence than manslaughter, is founded upon sound political reasoning, however sad and terrible some of its immediate consequences may be. The same instinct has compelled our colonies to raise a barrier against the inflow of coloured races on their shores. White inhabitants fear that they will be engulfed in a torrent of alien humanity, while the hope that the stronger race with its higher ideals may raise such immigrants, by education, example, and law, to be fit subjects for miscegenation is felt not to take into consideration existing conditions. The hope is pious, not practical.

[1] Inter-Racial Problems. Edited by G. Spiller. London: P. S. King and Son. Pp. xlvi. + 485. Price 7s. 6d. net.

There is a field for national and racial coöperation, in which no bounds are fixed, where no racial antipathies need enter, where inter-ethnic relations of the most intimate kind may exist, and where the "better understanding" and "friendly feelings" so properly desired by the promoters of the Universal Races Congress may have full scope. Science is rapidly becoming the great healer of national and racial discord, for it knows no colour barriers, and no distinction of language or religion. It is, in a word, universal, and its beneficial discoveries have become the common heritage of mankind. No department of science has perhaps contributed so largely to this humanising process as the science of medicine. The history of medicine from the time of HIPPOCRATES shows that it has always borne a foremost part in the general diffusion of knowledge and the better understanding of nations. Scientific medicine has been a true international missionary. The discovery by KITASATO of the bacillus pestis is as well known and appreciated as the work of LISTER or KOCH. The common aim of all medical research, in whatever part of the world carried on, is disinterested inquiry into the laws that govern health and disease, so as by their better understanding to lessen the sufferings of humanity. It cannot be denied that this must prove a powerful factor in bridging the gulf of race, and every fresh discovery in the field of medicine fortifies the growth of that comity of nations and races which the members of the Universal Races Congress so eagerly await. In every branch of scientific medicine there is now an international congress, and apart from the contributions to medical science it would be difficult to over-estimate the value of these cosmopolitan gatherings in the removal of national and racial prejudices. We are in complete accord with the ideals which the Universal Races Congress would endeavour to promote, but until mankind shall have developed more the attributes of Deity we cannot believe that so close a bond of brotherhood as racial admixture would be other than provocative of disaster. To help the evolution of the peoples towards such an end is an admirable ideal for all scientific men, for the world will be a finer place when it is ready for such fusion of its various populations; but to press now for miscegenation is premature, and likely to obscure for serious persons the value underlying the purposes of those who promoted the first Universal Races Congress.

Women and Medical Research.

THE Introductory Address delivered on Monday last at the London School of Medicine for Women by Sir HENRY BUTLIN, the President of the Royal College of Surgeons of England, will attract the notice of all who are interested in medical research and in the future of medical education for women, two subjects which may be regarded as one to this extent, that the capacity for research, whatever its object, must usually be the finest development of education, whatever the sex of the worker. Sir HENRY BUTLIN'S words are always eloquent and to the point; nor does he flatter when criticism is called for. In his address he briefly surveys the field of medical research by way of preface to remarks on the fitness of women to labour therein. He compares and contrasts the two methods of research—the

method by observation and the method by experiment, and that the former is nowadays out of fashion, at least in medicine, seems to us to be a matter for regret. Experiment, of course, is more attractive to modern minds, impatient of interruptions and delay, but with all its rapid and striking results it is a two-edged weapon, and it cannot take the place of accurate and patient clinical observation. Its value as an accessory to the fruits of bedside labour is enormous. There is, in short, room for both methods; some problems are best suited to one, some to the other, and those who would approach all questions exclusively from one direction must in a short time appreciate their ill equipment. In the case of cancer research, for example, as Sir HENRY BUTLIN clearly shows, each method supplements the other and neither can replace the other. In view of modern tendencies this, we think, should be pointed out, while the restriction of research to such procedures as those which at first sight have an immediate utilitarian object is clearly impossible. Here we would quote the admirable words of Professor F. GOTCH, which, although spoken some years ago on scientific investigations in general, may well be applied to medical research in particular. He said that the scientific method demands of the worker "that he should deem no natural phenomenon too insignificant or too ignoble for investigation, that he should grudge neither time nor labour in making and repeating observations and experiments, that he should have the fear of error constantly before him, and that he should be unaffected by any consideration as to the immediate practical utility of his work." It is, of course, a fact that the man who works solely for an object so cramps his scope that, when the longed-for object is really attainable, he may not recognise his own success.

Turning to the past work and future prospects of women in medical research, Sir HENRY BUTLIN dwells on the qualities of mind and heart necessary for scientific investigation, and declares that in such important characteristics as humanity, patience, industry, cleanliness, perseverance, enthusiasm, and manual dexterity women are as well equipped as men. And here he plants a shaft of criticism: he suggests that women cannot be relied on to furnish accurate records of fact. This is indeed a serious allegation, for extreme and habitual accuracy in making and recording observations is vitally necessary in every branch of scientific research. If it be true that intelligent and highly-trained women cannot be trusted to make accurate records of simple business affairs, then clearly they cannot be trusted to conduct and record investigations, and so long as this is the case they are not fitted for research. We hope that this question of accuracy and sex, now that it has been raised by so eminent an authority, will be sifted without passion or prejudice. Women are challenging men in every intellectual field, and in so doing they invite criticism and comparison. The charge of inaccuracy should awaken, not resentment, but anxious thought and inquiry. If, so far at least as medical and scientific women are concerned, the allegation falls to the ground, then they will be the gainers. If impartial inquiry upholds Sir HENRY BUTLIN'S suggestion, we should be disposed to lay the blame upon the upbringing of women and not upon their sex. Between diligence and true accuracy there is a distinction which is not solely temperamental, but is largely a matter of education. Accuracy in science implies trained intelligence. The habit of accuracy cannot be acquired suddenly, but must be developed during youth as an integral part of the character. If women are inferior to men in this respect then their progress in research will wait upon the heels of reform in the methods of general education for women. OLIVER WENDELL HOLMES, when asked at what age we should begin to live aright, answered, "Two hundred years before we are born," an answer which took into consideration the influence both of a long heredity and a stable environment. As Sir HENRY BUTLIN points out, few women up to the present have taken up medical research, though the success of CAROLINE HERSCHELL and Madame CURIE in other lines of scientific investigation proves that the highest positions may be open to them. Mr. BUTLIN'S interesting and suggestive address ends on a note of inquiry. Granted all other requisites, have women the breadth of mind to originate and to organise independent research, or are they only suited to carry out work designed and directed by men? Can they lead in science or must they always be led? Sir HENRY BUTLIN does not know, he will not predict, but he would have them try. His hearers no doubt took this as qualified encouragement.

Pioneer women have fought long and bravely for equal rights and opportunities for their sex in the world of medicine, and bit by bit their claims have been recognised and conceded. It can scarcely be said that women are already on equal terms with men in every professional respect; but many harsh disabilities have been removed, and a woman can now receive an excellent medical education under conditions almost as favourable for developing skill, knowledge, and resource as those offered to male medical students. If the relative opportunities as between the two sexes are ever really equalised, it may then be possible to decide whether women are inherently fitted to rival men, not only as clinicians, but also as original investigators. At present the conditions are not alike, and we venture the opinion that the full handicap will not be lifted from medical women so much by throwing open demonstrations or degrees or appointments to them as by revising the environment and training of school-girls, and especially of those who show early aptitude and inclination for intellectual pursuits.

Annotations.

"Ne quid nimis."

JUSTICE FOR THE JUKES.[1]

WE welcome a reprint of this well-known work, the last edition of which was published in 1877. "Juke" is the pseudonym given by Mr. Robert L. Dugdale to a family whose environment and lineage he investigated through seven generations, beginning with one "Max," a descendant of the early Dutch settlers, who was born between 1720 and 1740, and lived the life of a backwoodsman in New York State.

[1] The Jukes: A Study in Crime, Pauperism, Disease, and Heredity. By Robert L. Dugdale. With an Introduction by Franklin H. Giddings. Fourth edition. London and New York: G. P. Putnam's Sons. 1910 Pp. 120. Price 5s. net.

Two of his sons married two out of six sisters named "Juke," and the descendants of five of these sisters, to the number of 540, as well as 169 related by marriage or cohabitation, have been traced. They include criminals, prostitutes, inebriates, and paupers, as well as respectable persons. Robert Dugdale was a man with great powers of observation and sound judgment. His views, put forward more than thirty years ago, are fully in accord with the modern tendency to attribute ever-increasing importance to environment at the expense of heredity. There is considerable irony in the fact that his book should be so often cited as supporting precisely the opposite view. For this record of the Juke family has been quoted over and over again as an instance of the force of heredity in relation to crime, inebriety, and social degeneration. Upholders of the eugenic movement have delighted to draw a moral from the supposed story of the Jukes, and have often done so in a prominent way in our own columns, where recently the following can be found: "Then there is the famous Juke family. Ada Juke, known as the 'mother of criminals,' left 1200 direct descendants, of whom nearly 1000 were criminals, paupers, inebriates, insane, or on the streets. The cost to the State directly in consequence of this inheritance was £260,000, while the indirect loss cannot be estimated." We have taken the same line, but if the original book is read in the light of Professor Giddings's preface it seems that the Juke family have been unfairly treated. The statistical summary shows that of the 709 descendants of the five sisters and those of "x" blood there were 76 criminals, 142 who received outdoor relief, and 64 in almshouses. No special investigation into the number of mentally deficient persons is recorded, but the tables show only one person of Juke blood as insane and one idiotic. The inferences in respect of inheritance cannot be justified. Professor Giddings points out in the introduction that the book is in no way a demonstration of hereditary criminality or degeneracy, and that the author never made any such claim for it, forgetting that a series of recorded facts might have a lesson which the recorder did not seek to convey. But he utters a caution against mistaking coincidence for correlation, which has clearly been needed, for wherever the facts appear to indicate the inheritance of vicious tendencies he points out that they can be explained as the result of a continuous bad environment. On the other hand, he quotes instances of children of vicious parents who under the influence of a new and good environment have become useful members of society. The general conclusion to be drawn from the book is that where the organisation is structurally modified, as in idiocy and disease, heredity is the preponderating factor in determining the career. In other cases the environment has more influence than the heredity. Pauperism and crime are to be overcome by training and education. The investigation into the Juke pedigree provides material for illustrating the fallacies which are frequently made when dealing with a "family" without having given a scientific definition to that word. Usually deductions are based on the assumption that a family consists of a number of persons who have descended from a single pair in a kind of ever-broadening stream. It is forgotten that were it not for the marriage of cousins an individual of the seventh generation would have 64 ancestors of the first generation all standing in precisely the same relation to him, and 126 ancestors altogether. In the loose statements made about the family of Juke the outside blood is always ignored, and the unfortunate "Ada" is made responsible for all the criminals, and this to an exaggerated number. In her detailed biography she is described as being "temperate and not criminal"; the worst things against her are that she was a harlot before marriage and was not industrious. Similar descriptions apply to most of her children. It is from those who married into the third and fourth generations that the worst strains seem to have been introduced. An interesting instance is given in the case of "Bell," the second sister. Her three eldest illegitimate children are described as being honest, industrious, and self-supporting. The fourth child was not a criminal, but he married outside the Juke blood, and among his children are found criminals. If any inference at all is justified, it is that the "x" blood and not the Juke blood was responsible for these particular criminals. Yet everyone believes, because we have been so often told it, that the Juke strain was the one at fault. A false impression once generally accepted is difficult to correct, but we hope that this new edition of Mr. Dugdale's book will be read by those who wish to use its lessons in their public pronouncements.

THE INDIAN RESEARCH FUND.

LAST year the attention of the Government of India was directed to the opinion expressed by its expert scientific advisers that the progress of public health in India might be greatly advanced by the establishment of a special fund devoted to defraying the cost of research work in connexion with public health and hygiene. After the question had received due consideration the Government accepted the views of its scientific advisers, and as a result it is now announced that a sum of 5 lacs of rupees has been set aside as an Indian Research Fund. The primary object of this will be to carry out the policy, which has already been adopted in India for some years, of making a direct attack upon certain of the more important epidemic diseases. It is very properly maintained that scientific investigations form the starting-point and basis of this policy, experience in other countries as well as in India having demonstrated that when the actual sources of infection and the mode in which it is transmitted have been definitely ascertained, the measures for preventing and controlling the disease become greatly simplified and are likely to prove far more effective than those recommended before such knowledge had been gained. From an editorial record in the recently published third number of *Paludism* (the organ of the Central Committee for the Study of Malaria in India) we learn that the organisation proposed for carrying out the objects of this newly established research fund is to be an association consisting of permanent and temporary members. The control and management will be vested in a governing body, of which certain members will be appointed to act as a Scientific Advisory Board, through whom proposals in connexion with the scientific objects of the association will be submitted. The proposals approved by the governing body will be carried into effect with the aid of working committees, of which the Central Committee for the Study of Malaria will be one. It is hoped to form committees to organise and carry on study in regard to the following: (1) medical entomology; (2) vital statistics and the more general problems of disease; (3) cholera; (4) plague; and (5) problems of practical sanitation and especially the preparation of schemes for model towns and other measures by which the efficacy of sanitation is demonstrated to the public. It will be seen that this programme includes further investigation of three at least of the most fatal but preventable diseases in India—malaria, plague, and cholera. Malaria annually carries off more than a million of the inhabitants of India, and in epidemic years a good many more. We have recently alluded to the terrible sacrifice of life caused during the last 14 or 15 years by plague in India, and this still continues; and as cholera has been epidemic in India for a long series

of years, and still slays thousands of the population every year, we rejoice to see that opportunity will be taken by means of the research fund to make further investigation with a view to lessen the serious mortality from it as well as from the two other diseases which at present are the scourges of India. It is particularly gratifying to find that general sanitation is to receive its due share of attention. The construction of sanitary works or buildings must lead to far-reaching and unexpected effects in benefiting the general health of the people. We also learn from *Paludism* that in anticipation of an allotment of money from the research fund the Central Malaria Committee has already formulated its proposals, which are to be submitted in due course to the governing body. These include research as to: (1) prevention of malaria among troops, (*a*) by experiments as to the best modes of protecting the soldiers, and (*b*) investigation into the efficacy of quinine prophylaxis among the military; (2) the institution of malariometric investigations; (3) inquiry into the bionomics of anopheles; and (4) inquiry into education propaganda. The carrying out of these and similar researches cannot fail to prove of benefit to the inhabitants of India, while contributing largely to the general stock of available knowledge. The money voted to the research fund we feel sure will prove a good investment, leading to the reduction of the high death-rate in India, besides preventing much unnecessary suffering.

PLEURAL EFFUSION WITH RIGIDITY OF THE PLEURA AND MEDIASTINITIS.

AT a meeting of the Société Médicale des Hôpitaux of Paris on June 30th M. Millardet reported a case of pleural effusion with an unusual complication which produced a puzzling combination of signs. A youth, aged 19 years, previously in good health, was seized with rigors and pain in the left side on Feb. 18th while in Paris. He did not seek medical advice, but returned home to Rennes, and was admitted to the Hôtel Dieu on the 24th. On percussion the left chest all over, in front and back, was absolutely dull, suggesting a large effusion with a lung so collapsed that air no longer entered it. But on auscultation M. Millardet heard to his great surprise well-marked double pleuritic friction, such as would be found in cases of a small effusion. As in the latter, he also found well-marked ægophony and whispering pectoriloquy. Vocal fremitus, which with so much dulness should have been abolished, was present, and scarcely less than on the right side. In certain cases of pneumonic consolidation of the lung a small amount of pleural effusion may, in consequence of the incompressibility of the lung, mount high in the pleural cavity. But in such cases there are dyspnœa, expectoration, tubular breathing or râles, and displacement of the neighbouring organs by the effusion, which is under pressure. In this case there was no dyspnœa, cough, or râles—a remarkable fact with an effusion reaching to the clavicle—though the heart was displaced two finger-breadths to the right of the sternum. Traube's space was not encroached upon and remained tympanitic. There was only one plausible hypothesis—infiltration of the pleura producing rigidity. Assuming this, the fluid could not push back the lungs or neighbouring organs; it would with difficulty separate the parietal from the visceral pleura, and, though in small quantity, might extend through the whole thorax. It would be necessary that the whole pleura, visceral and parietal, mediastinal and diaphragmatic, should be rigid. The only exception would be the layer covering the pericardium, as the heart would offer resistance to pressure; but in this case it would suffer compression, producing dyspnœa. As none was present the rigidity of the pleura must in the present case be general. The objection arose that such rigidity usually occurs in adults who have long been subjects of chronic rheumatism or chronic infection. In this case there was nothing to suggest syphilis or tuberculosis. Paracentesis was decided on, but its difficulties were foreseen. Fluid contained in a rigid cavity might not yield to aspiration unless the admission of air was provided for. A second needle was prepared for this purpose. The *interne* failed to pass the trocar into the pleural cavity, though forewarned of the difficulty and used to paracentesis. It was passed with difficulty by M. Millardet in consequence of the great resistance of the pleura. 1600 grammes of brownish sero-fibrinous fluid were withdrawn. Contrary to what usually happens in paracentesis, the lung was never once felt beating against the cannula. This was explained by the want of suppleness of the visceral pleura which held down the lung. After the paracentesis Traube's space was exactly as tympanitic as before and the cardiac apex remained two finger-breadths to the right of the sternum. Evidently the pericardium had contracted adhesions to the mediastinum. Cytological examination of the fluid showed some red blood corpuscles and numerous lymphocytes—a condition which was in favour of a tuberculous origin of the pleurisy, but did not exclude syphilis. It was intended to perform the Wassermann reaction, but the patient left hospital on his own initiative. He was seen again a month later. The heart had almost regained its normal position and pleural friction was present. The pulse was 126—a fact which was in favour of the diagnosis of tuberculosis in spite of the apparently robust appearance of the patient. The case not only offers an interesting problem in diagnosis but is important in regard to treatment, for it gives warning of the difficulties of paracentesis.

THE PHARMACIST OF THE DAY.

Dr. J. Macdonald Brown, at the opening of the session of the School of Pharmacy of the Pharmaceutical Society on Wednesday, Oct. 4th, delivered an interesting inaugural address with the above title. Disclaiming any intention to trace the history of pharmacy through the ages, he none the less dwelt humorously upon the evolution of pharmacy from alchemy and the gross quackery of the ancient nostra to its present position as a scientific profession. Of the National Insurance scheme he hoped good things, but while speaking of advances made, and still to be made, in the State recognition of pharmaceutical work, he alluded to a recent piece of legislation in severe terms. "One cannot but regret," he said, "the step taken by the Government when, in 1908, the legislature sanctioned a change in the poison laws, by which arsenic and the alkaloids of tobacco were liberated from the operation of the Poison Schedule, and it became enacted that certain classes of ordinary tradesmen (men who had received no education or training in the handling of poisons) might sell these dangerous poisons to the public, simply by the acquirement of a licence from the public authority in their particular town or district—a licence which appears to have been granted in most cases as a mere matter of form. To think that such looseness of action in a matter so important could have been sanctioned by any Government in the world is monstrous and incredible." Dr. Brown then described the course demanded of the pharmaceutical student, in the course of which he bewailed, as too many of those interested in medical education have had to do, the tendency of the present day to spoon-feed those in the state of pupillage. In addition, he said, to lectures, demonstrations, and text-books, coaches and crams of the most varied character abounded, and in

his opinion these flourished mainly because the tendency of the day was to work for the examination and not for the knowledge itself. This is certainly true, but it also is a position exceedingly hard to alter. Examinations are necessary; such tests must be rigorously applied for the protection of the public, and all that educational authorities can do is to see that the character of the examination is kept as practical as possible, that due stress is laid both in the papers and in the *viva voce* questions upon essential principles, and that the examiners are selected with regard to the responsibilities which they have to discharge.

WOODY PHLEGMON OF THE NECK.

IN 1893 Professor Paul Reclus described under the name of "woody phlegmon of the neck" a form of inflammation which he believed to have been previously unrecognised. He said that the condition occurred in men over 50 in broken-down health, but free from other disease. A slowly extending, board-like infiltration developed in the neck, sometimes in front, sometimes at the side. The skin gradually became of a wine-red, blue, or purplish colour. There was no fever or pain. At first cancer of the skin was simulated, but after five or six weeks œdema and fluctuation appeared, and pus was discharged spontaneously or after incisions. The phlegmon then slowly healed, but in one case the patient succumbed to œdema of the glottis. Professor Reclus thought that this form of inflammation might occur in other parts and be confounded with cancer, actinomycosis, or tuberculosis. He believed that it was due to microbes of low virulence. Cases were subsequently described by many other surgeons on the continent. In the *Journal of the American Medical Association* of July 29th Dr. Charles A. Powers has reported three cases. In the first a labourer, aged 50 years, in poor health, came under observation with a hard, fixed, bluish mass, something resembling a flattened apple, in the middle line beneath the lower jaw. The history was that he had suffered from a tender swelling in the floor of the mouth for one month. This had twice been incised with discharge of pus. The swelling beneath the jaw came on slowly, painlessly, and progressively. On examination it was of stony hardness and fixed to the deep tissues; the skin was adherent and slightly œdematous. A provisional diagnosis of carcinoma was made. Under local anæsthesia the swelling was deeply incised. The cut surface was hard and greyish-white; no pus was encountered. A piece was submitted to Professor J. A. Wilder of Denver for microscopic examination, and he reported it to be fibrous inflammatory tissue. Treatment consisted in local moist applications and tonics. In three weeks the mass greatly increased in size and small superficial foci of suppuration appeared. On incision they yielded thin pus containing staphylococcus pyogenes albus and aureus. After three or four weeks the mass began to diminish slowly, and the patient passed from observation. He was seen again four months after the onset. There was some thickening beneath the jaw, and its movements were somewhat restricted. During the height of the swelling deglutition was interfered with. In the second case a man, aged 45 years, was seen. Two months before he had suffered from infection round the left parotid gland, and on incision a little thin pus was evacuated. The inflammation did not subside, but extended to the left side and back of the neck, painlessly and without fever. On examination the whole of the left side and back of the neck showed a diffuse hard swelling which extended from the occiput and mastoid process above to the level of the spinous process of the fourth cervical vertebra below, and forward towards the jaw and across the median line. The swelling was fixed, and the overlying skin was attached to it and somewhat discoloured. It gave the impression of malignancy. On incision it was hard and whitish, and looked like carcinoma. Complete removal was impossible. Professor Wilder examined excised portions and reported that the condition was inflammatory fibrosis of muscles and fasciæ. At no time while the patient was under care was there suppuration. The patient died three years later, but the cause of death could not be ascertained. In the third case the woody phlegmon followed acute inflammation of the connective tissue of the neck (Ludwig's angina). In a recent letter to Dr. Powers Professor Reclus states that he does not consider woody phlegmon a definite morbid entity, but a reaction which can be provoked by any pathogenic germ, not only by the ordinary agents of suppuration but also by fungi (actinomycosis and sporotrichosis). The reaction is characterised by the formation of fibrous tissue and may occur in other regions than the neck, for example, around the abdominal viscera, especially in the right iliac fossa or around the kidney. The so-called perinephritic sclerosis is practically a woody phlegmon.

THE LONDON MEDICAL EXHIBITION.

THE London Medical Exhibition held annually in the Royal Horticultural Hall, Vincent-square, Westminster, continues to gain support from professional visitors. The exhibition, which was held this week, revealed a further development upon scientific lines, which proves that, apart from the commercial aspect of the meeting, a real opportunity is offered to the surgeon and physician and their assistants to become practically acquainted with recent advances in pharmaceutical preparations, special dietetics, surgical appliances, sanitary devices, and so forth. The exhibition attracts also the manufacturers who provide the profession with its armamentarium, and the result is that the medical man finds his visit interesting and instructive. The invitations to the demonstrations are sent to medical men only, a plan which secures an audience bent on seeing all that counts for progress in medicine and a class of demonstrator which issues no appeal to the layman. The increasing success which attends this exhibition year by year must be attributed to this policy, for it draws larger attendances on each occasion, and its professional character is well maintained. The exhibition this year has been marked particularly by the excellent demonstrations given of advanced therapeutics and of fine pharmaceutical products, while a further interesting feature was formed by the exhibitions given of the applications of radio-activity in medical practice.

LIGATURE OF THE SPERMATIC ARTERY IN THE OPERATION FOR VARICOCELE.

SOME eight years ago Dr. E. Styles Potter of New York advocated the treatment of varicocele by ligature of the spermatic artery as well as the veins, and now, in the June number of the *International Journal of Surgery*, he reports on 214 cases of the employment of his method, and the results which he has obtained have served only to strengthen his opinion of its value. It is generally held that it is important to avoid tying the spermatic artery when excising the spermatic veins, as otherwise atrophy of the testis is liable to occur. Dr. Potter, however, has never seen atrophy following his operation. He has been able to follow up 67 of the 214 cases, and some of these for several years, and in none of these was any atrophy to be seen. In one case orchitis appeared, but no cause for it could be found. Relaxation of the scrotum with ecchymosis of the scrotum and penis frequently occurred, but it passed off in a few days. Dr. Potter considers that when the spermatic artery is tied the blood-supply of the testis is carried

on by the artery of the vas deferens, so that he sees no reason why atrophy should occur. He has not yet tried ligature of the spermatic artery without at the same time tying the veins, but he hopes that it will be done, and he says that he expects that a gradual atrophy and absorption of the veins will occur. It is probable that the artery has been sometimes tied unintentionally, for it is not easy to distinguish the spermatic artery from the veins at an operation.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

DURING October a series of demonstrations of museum specimens will be given by Professor A. Keith and Mr. S. G. Shattock. The series commences on Friday, Oct. 13th, at 5 P.M., when Professor Keith will deal with specimens added to the museum during the last three years illustrating "Various Recent Discoveries in the Anatomy and Pathology of the Heart." The second demonstration will be given by Mr. Shattock on Monday, Oct. 16th, at 5 P.M., on specimens illustrating "Necrosis," a section of the museum which is being greatly extended at present. The other demonstrations will also be given on Fridays and Mondays throughout the month as announced in our "Diary of the Week." Recent additions to the museum provide Professor Keith with an opportunity of giving a very complete exhibition of the lesions seen in acromegaly.

THE PRESERVATION OF VACCINE VIRUS IN HOT COUNTRIES.

WE have received from Dr. J. Dickson Hunter, of Arequipa, Peru, the paper to which he alluded in our columns last week. This was originally published in the *Bulletin de la Société de Pathologie Exotique* by M. Pierre Achalme and Dr. Marie Phisalix, and gives details of what is described as a practical method of preserving vaccine lymph in tropical countries. They find that the glycerination of the lymph is less efficacious in hot climates than in temperate ones. The glycerine prevents the development of the bacteria present in the epidermal débris existing in the lymph. This bactericidal action is, however, apparently not directly produced by the glycerine, but by the soluble ferments present in the cells and extracted by the glycerine. It is found that the preservation of the vaccine in hot countries is more certain if glycerine is added to the crude material derived from scratching the vesicles than if this is previously rubbed up and triturated. The reason of this is that these procedures set free the intracellular ferments more completely, and that these are more powerful at temperatures near 37° C., and therefore attack the vaccinal agent as well as the extraneous organisms. After many trials M. Achalme and Dr. Phisalix have adopted the method of desiccation as the best means of preserving the vaccine at warm temperatures. They state that this observation is not absolutely new, since Wurtz of the Belgian Vaccine Institute has shown the advantages of the procedure, and Carini has demonstrated the increased resistance of powdered vaccine to raised temperatures. M. Achalme and Dr. Phisalix suggest that this process of rapid desiccation hinders the growth of bacteria and the activity of the soluble intracellular ferments, but they maintain that in order to obtain these effects it is necessary to secure complete desiccation and to preserve the dried material in sealed tubes because of its hygroscopic properties. The method they have adopted is to take 30 grammes of crude vaccine, obtained directly from heifers, and to dry it rapidly *in vacuo* on porous plates in the presence of sulphuric acid. After 12 hours the process of desiccation is complete and the vaccine is converted into a horny brittle mass. Some of this material they have preserved in sealed tubes in an incubator at a temperature from 37·5° to 38° C. for a year, and on inoculating it into heifers have obtained a typical eruption of vaccinia. They have also found that the vaccine keeps better in fragments than in powder, and better *in vacuo* than in contact with air. On investigating the effect of various temperatures they have found that after keeping the vaccine for six days at 57° C. it would still give a reaction, but that it was much weakened, that a temperature of 45° C. was also slightly injurious, but that those of 41° C. and 42° C. exerted no harmful action. They therefore recommend the adoption of this method for the transport of vaccine to tropical countries. The dried vaccine can be very readily prepared for use, since in virtue of its marked hygroscopic character it will readily absorb either normal saline solution, weak glycerine and water, or sterile water, any of which rapidly convert it into a pulpy mass very convenient for use. The supply of active vaccine for warm climates is an important matter. The method described has the merits of simplicity and convenience, and if it can be shown that the growth of extraneous organisms is equally well prevented by its use as by glycerination, it should prove a valuable help in the preservation of vaccine for these climates. Dr. Dickson Hunter's interesting letter sufficiently proves the need for a desiccated and efficacious vaccine.

HEMLOCK AS A STATE POISON.

IN ancient Athens the prisoner condemned to death was made to drink the juice obtained by the decoction of hemlock (κώνειον, the Latin *cicuta*), the seeds of which were pounded in a mortar as the first step in the preparation. The poison acted slowly, its efficacy consisting of its refrigerating power (the *vis refrigeratoria*, according to Pliny the Elder) —a process which spread from the lower extremities to the heart, when death ensued accompanied by spasm or convulsions, symptoms expressly noted by Plato in the case of Socrates. Its action was antagonised by wine, which was often used as an antidote, beating the patient, and so impeding its characteristic action, a result also obtained by the effort and excitement of discussion, as was stated to Socrates by the expert in whose charge he was, so that the dose had often to be readministered to a talkative subject once or even twice. Phocion, the great antagonist of Socrates (according to Plutarch), was put to death by the draught of hemlock as prescribed by the State, and before him, as narrated by Xenophon, Theramenes was executed by the same method. Of late years some doubts have been thrown on Plato's account of the drug's action, hemlock juice (it is alleged) producing symptoms of a quite opposite kind. These doubts, however, have just been disposed of by the professor of materia medica in the Medical School of Dundee, Dr. Charles R. Marshall, who, in a note communicated to Professor Burnet of St. Andrews, the most recent editor of the "Phaedo," maintains the soundness of Plato's narrative, the doubts referred to being, in his opinion, "unworthy of serious consideration." Although he admits that *Conium maculatum* is somewhat peculiar in its action, and that the symptoms ensuing on its exhibition may vary with the dose, and probably with the individual, still he is decidedly of opinion that the death of Socrates was due to the said conium and in the manner described by Plato. The whole subject of poison in antiquity as a means of State-execution or of suicide is deeply interesting and might well inspire a special treatise at the hands of the toxicologist. Bull's blood is said to have been taken with lethal purpose and effect by Themistocles, and Phocion's great rival Demosthenes,

according to Plutarch's dramatic account, took poison in the Temple of Poseidon, graduating the dose, which he sucked from the point of a writing-quill, so that it might not take effect till he was well out of the sacred precincts, which were thus immune from desecration by self-murder committed within them. Hannibal is said to have carried in a ring the poison by which he committed suicide; but what that poison was is still a matter of controversy, as is also that employed by Demosthenes. In mediæval times such methods of "cheating the gallows" were common enough—witness the cynical self-possession with which (in Scott's "Fair Maid of Perth") the mediciner Henbane Dwining baulked his executioners on the ramparts of Falkland Castle.

THE ASYLUMS OFFICERS BILL.

A BLUE-BOOK has been issued containing the special report of the Select Committee on the Asylums Officers (Employment, Pensions, and Superannuation) Bill. The committee, we are glad to note, shows a full appreciation of the very arduous and responsible duties imposed on asylum attendants, and recognises that the conditions under which these duties are carried out must be materially improved if a proper standard of excellence is to be maintained in the personnel of our institutions for the insane. At present, according to the estimate of the Lunacy Commission, the number of hours' work required of the asylum attendants averages for England and Wales 84 per week. This is obviously excessive, especially when regard is had to the nature of the work, much of which, as the committee justly observes, is tedious, monotonous, wearing, and not free from some personal risk. That a more reasonable system is quite practicable is shown by the example of the London County Asylums, in which the male attendants work on an average 66 hours on the day and 63 hours on the night staff, and the nurses 72 hours on the day and 65 hours on the night staff. Considering the demand which the nursing of the insane makes on tact and temper, these hours seem quite long enough, and this view, we may add, is to be urged not less in the interest of the patients than of the attendants themselves. The committee recommends that Parliament should impose a statutory maximum, and it suggests as a reasonable limit 70 hours a week for the day staff and 60 hours for the night staff. It deprecates, however, any attempt to introduce a stereotyped system, and it advises that within the statutory limits each visiting committee should be empowered to draft its own scheme of hours of duty and periods of leave. It is satisfactory to note that the committee disapproves strongly of the proposal to pay overtime, a system which in asylum work has obvious disadvantages as compared with the alternative method of allowing equivalent leave for extra duty. With regard to superannuation, it is very reasonably suggested that as the salaries of nurses are generally lower than those of male attendants, an effort might be made to redress the balance by granting pensions to nurses on a higher scale. The Bill, as amended in committee, should go a long way towards removing the very real grievances under which asylum attendants have laboured; it is therefore to be welcomed as a measure of justice to a very deserving body of public servants, and further, as a reform which must tend to promote the efficiency of the institutional care of the insane.

THE first Hunterian lecture will be delivered by Dr. T. B. Hyslop on Oct. 11th, at 9 P.M., on "Intracranial Murmurs in their Relationship to Tinnitus Aurium," at the London Institution, Finsbury-circus. The lecturer will deal with some of the more important of the anatomical and physiological problems of intracranial physics, including the pulsatile, respiratory, and peristaltic movements of the cranial contents. Examples will then be given of morbid affections of the vascular and lymphatic systems which may, in some instances, be attended by acoustical phenomena, which may be observed both subjectively and objectively. All members of the medical profession are invited to attend.

THE undermentioned gentlemen have received the authority of His Majesty the King to accept and to wear the decorations which have been conferred upon them by His Highness the Khedive of Egypt—viz., the Third Class, Imperial Ottoman Order of the Osmanieh, to Mr. Alexander Granville, of the Egyptian Ministry of the Interior; and the Third Class, Imperial Ottoman Order of the Medjidieh, to Dr. Reginald Gower Kirton, Chief Medical Inspector of Prisons, Cairo.

THE death has occurred of Dr. Joseph Bell, of Edinburgh, consulting surgeon to the Edinburgh Royal Infirmary, for many years editor of the *Edinburgh Medical Journal*, and admitted by Sir Arthur Conan Doyle to be the prototype of Sherlock Holmes.

THE Harveian Oration will be delivered by Dr. C. Theodore Williams at the Royal College of Physicians of London at 4 o'clock on Wednesday, Oct. 18th.

REPRESENTATION OF HONORARY MEDICAL STAFFS UPON BOARDS OF MANAGEMENT OF VOLUNTARY HOSPITALS.[1]

BY ERNEST S. REYNOLDS, M.D. LOND., F.R.C.P. LOND.,
PHYSICIAN TO THE MANCHESTER ROYAL INFIRMARY, AND CHAIRMAN OF THE MEDICAL BOARD.

SOME ten years ago, owing to an acute disagreement between the lay and medical elements of one of the London hospitals, a series of articles appeared in the *Practitioner*[2] on the question of hospital management from the lay and the medical points of view. The arguments in favour of medical representation on boards of management are so convincing that further discussion on the subject seems to me to savour of the profitless undertaking of flogging a dead horse; and I was unwilling to undertake the request that I should read this paper until I learned, with surprise, that there are still hospitals in this country in which such arrangements do not exist.

To shorten my argument, I take it for granted that every hospital possesses a lay board of management (composed entirely, or almost entirely, of laymen) and a separate medical committee (composed of the honorary medical and surgical staff), and these I will allude to below as "the board" and "the staff" respectively.

Now it is always well in dealing with an adversary in argument to consider as calmly as possible why it is he can persist in being so adamant as not at once to alter his opinion in accordance with the views you put before him, and so far as I can surmise the reasons for a purely lay administration of hospitals are: (*a*) the question of ownership, (*b*) the finding and spending of money, (*c*) business capacity, (*d*) possible censure of one or more members of the honorary staff, and (*e*) lay suspicion of medical hospital practice. I will consider these seriatim.

(*a*) *Ownership.*—I suppose that in law a voluntary hospital is owned by the trustees, who are entirely, or almost entirely, laymen, and it naturally seems to follow that they should manage their own property. This highly complex organism, a hospital, comprises not only buildings and paid lay and medical officers, but also as a most important and indispensable part of its working units an honorary medical staff; and

[1] A paper read at the Conference of the British Hospitals Association, held at Manchester, on Sept. 29th, 1911.

[2] Vol. xiii., 1901.

just as the paid officers have naturally no voice in the management, so it is supposed that the honorary staff should have no voice. But it should be remembered that a large number of hospitals in this country have been initiated by medical men in the district, partly from philanthropic motives, and partly, to put it broadly but in no sinister sense, for purposes of self-education and advertisement, and it seems somewhat arbitrary that having once started the hospital they or their successors should take no further part in the management. Secondly, the honorary staff are not paid except indirectly by the experience gained and the advertisement of being on the staff, and if owing to bad management the hospital is a failure the reputation of the staff may suffer enormously.

(*b*) *The finding and spending of money.*—The obtaining of money to maintain a hospital is largely the work of the board, but this does not seem to me to be a reason why the staff should not have a voice in the expenditure. I am sure the Chancellor of the Exchequer could not well object to the First Lord of the Admiralty and other members of the Cabinet having a "say" in the Naval Estimates. Moreover, it is by no means unknown for members of the honorary staff not only to contribute to the funds of the hospital, but also to obtain large sums from their richer patients.

(*c*) *Business capacity.*—It is frequently stated, and in the articles in the *Practitioner* already alluded to is rather insisted upon, that members of the medical profession are very lacking in business capacity. I admit that some of them are, but I have seldom known a successful medical man who was not businesslike in his habits. Want of business capacity is a fault which has been commonly associated for centuries with scientists and artists and has frequently been made the subject of mirth, and in spite of this, such unbusinesslike people have won the greatest renown, often, however, without making great fortunes. But taking the average run of successful doctors they are in my experience quite as businesslike as other members of the community. I have even known more than one unbusinesslike lawyer.

(*d*) *Possible censure.*—It may be urged that if it is deemed necessary to censure a member of the honorary staff either for irregular attendance or irregular conduct it would be difficult to do so if the member himself or one of his colleagues is sitting on the board. But, firstly, such occasions are very rare; and, secondly, it is exactly on such occasions that mistakes may be made by laymen which a word from a member of the staff will rectify at once and so prevent possible friction and misunderstandings.

(*e*) *Lay suspicion.*—Finally, it may be argued that the staff should not be represented on the board because of the suspicion which many of the lay public unfortunately have about medical work in hospitals, and especially in hospitals to which medical schools are attached. The idea is that "the doctors must be looked after." I do not believe there is the slightest foundation for this suspicion, but, knowing that it exists, I think it is in the highest degree desirable that hospitals should be managed by laymen, who should be in overwhelming preponderance in number on the board. But this is no reason why some of the board should not be drawn from the staff—rather, indeed, that they should be present, so that they may hear at first hand, and be able to correct at once, unjust allegations made against them or their colleagues.

The above are the only reasons I can think of for the exclusion of staff representatives from boards of management; possibly other reasons may be brought forward by the members of this conference.

Let us now consider reasons why the staff should be represented on the board. It is obvious that some means must exist by which the views and requests of the board and of the staff can be communicated one to the other. The three methods of intercommunication are: by resolutions placed on the minute book or forwarded by letter; by conference; or by direct representation of members of the staff on the board. A point arises here which may be at once disposed of. It may be argued that if the staff is represented on the board of management the latter should be represented at the meetings of the staff. But as a matter of experience, the meetings of the staff are taken up almost entirely with purely medical or teaching matters, and also (at any rate at the Manchester Royal Infirmary), in the rare event of the board wishing to discuss matters with the full staff, a conference is always most readily arranged.

In the method by resolution or by letter the communication may be ignored by the other parties, it may be misunderstood or may not be clearly and fully worded, and may thus require a whole mass of correspondence, thus causing a delay of weeks or months over a matter which a personal explanation would settle in a few minutes. The method by conference is better, but again involves unnecessary delay in arranging a time and place to suit all parties. By regular representation these delays and misunderstandings are at once done away with. Misunderstandings may and do arise first because of the different points of view from which lay and medical men look at certain questions, and, secondly, because of the somewhat extraordinary ignorance sometimes displayed by lay members of hospital boards about hospital matters, and not unfrequently even on matters relating to the very hospital on whose board they serve. This ignorance may be found more particularly in those members who may possibly attend quite regularly, but who are very busy public men who have already too many irons in the fire. Examples of misunderstandings because of a different viewpoint may arise on certain subjects which are principally professional but on which the layman sometimes thinks his knowledge is of great importance, such subjects as relate to the decoration, furnishing, ventilation, warming, and alteration of wards, the expense or utility of certain dietaries, the use of alcohol and the amount ordered, the necessity or otherwise for special medical and surgical appliances or methods of treatment proposed by the staff which some layman may consider to be a mere fad, or some method proposed by the layman which the staff know to be a fad; and last, but by no means least, letters which sometimes come, even in the best regulated institutions, complaining of the treatment which patients have received. By direct representation also matters which have been dealt with by the medical board and entered briefly on their minutes can be at once, if necessary, explained in full detail before the lay board. But in many other subjects which arise at the meetings of the lay board, such as those relating to pure finance, many legal matters, the management of servants (other than medical), the placing of contracts and similar purely business affairs, the layman is, and ought to be, paramount, and such matters are better left alone by the staff even if present at the board meetings.

I have worked at hospitals under lay boards both with representatives of the staff and without representatives. I was resident medical officer (and as such was also secretary of the medical committee) of the Manchester Royal Infirmary for the four years 1887 to 1890, and during this time I remember many differences of opinion between the board and the staff, some of these being of a somewhat acute nature; and at times each body, anxious to maintain its dignity, was as far apart from the other as the Lords and the Commons have lately been. This was a bad thing for the constitution of the hospital, but I was so used to this that I hardly knew there was a more perfect way. This I learned when as medical officer and visiting physician to the Manchester Workhouse Infirmary I was asked by the board of guardians to attend regularly at its fortnightly meetings. I then found how easy it was to straighten out in a few words what might otherwise, but for my presence, have been very crooked matters, and how as a result for the 16 years I was an officer of the Poor-law and in charge of a hospital of nearly 2000 beds practically no friction occurred, and certainly none of a lasting character.

About 11 years ago the board of management of the Manchester Royal Infirmary arranged to have representatives of the staff to sit with them, and as one of the physicians I have seen with the greatest pleasure the enormous improvement in the relationship between the board and the staff as compared with what I formerly knew, so that since this change I have never known any friction whatever to occur, and the utmost good feeling exists between the various members of the board and the staff. The system arranged seems to me to be so admirable that perhaps I may be permitted to describe it in a little more detail.

The board of management consists of certain lay trustees, 21 in number, elected by the general body of trustees at their annual meeting. This board meets once a month; exactly the same gentlemen meet once a week as a house

committee. The medical committee consists of all the members of the honorary staff, 23 in number, and meets regularly once a month to discuss any matters relating to the treatment and well-being of the patients, the diet sheets, surgical instruments, the sanitary state of the wards, the consideration of cases which have been over three months in the hospital, and all questions relating to the teaching of students. At the January meeting each year the medical committee elects by ballot four of its members to represent them on the board of management. As a rule—and it ought to be a rule—two of the elected members should be physicians and two should be surgeons, one of the four, however, being from time to time chosen from the honorary officers in charge of special departments, such as those of gynæcology, eye or ear diseases; and, as a rule—and again it ought to be a rule—no member should serve as a representative for more than two years in succession, for it is most important that no one member of the staff should obtain an undue influence on the board. These four elected members now become full members for the year of the board of management and are summoned by the general superintendent and secretary of the infirmary to all meetings of the house committee and the board of management and can take part in all discussions on any subject and can vote. As a matter of fact, they do not interfere as a rule with any subject with which they have no concern, such as finance, &c., to which I have already alluded as being purely lay in nature. They are there more to explain and, if necessary, to advise on points which I think all the members present would consider to be proper for them to deal with, and I do not know of any case in which the explanation or the advice has been resented.

As I have said, this system has worked in the most perfect way at the Manchester Royal Infirmary. At other hospitals, although the staff is represented on the board, its representatives are not allowed to vote. This is a point which does not seem to me to be of any great importance; the thing that matters is the actual presence of members of the staff with permission to explain and advise. At other hospitals the whole of the members of the staff sit on the board. If the staff is small in number and the lay members are preponderatingly large in their average attendance, I do not see any great objection, but otherwise I do, for if there is about an equality in numbers the public might think the staff was managing the hospital, and this is an idea which it is advisable should not exist. Another objection is that if the whole staff is allowed to attend then there may be occasions when no member of the staff is present, each depending too much on the others, for what is everybody's and anybody's work is nobody's work, whereas a few elected representative members of the staff have put upon them the duty of regular attendance. And it is very necessary that this attendance should be regular, for by experience I know how often at the end of some ordinary meeting, just as members are rising, some question is asked or some letter is read which at once fixes the members to their seats and keeps them there for another hour's discussion, and frequently such matters arise which involve and require medical advice and explanation.

I should like before closing to mention one comparatively small matter but which is important. At some hospitals, instead of, or in addition to, members of the active staff sitting on the board a member of the retired staff is present. This is to my mind undesirable, and especially so if he is the only medical member present, members of the active staff not being admitted. It is undesirable because members of the retired staff have a tendency to lose touch with or to lose sympathy with the work of younger men, and the advice they may give to the lay members of the board may be diametrically opposed to the views of the active staff and their presence on the board may become a hindrance to the progressive work of the hospital.

To summarise, I would suggest that in every hospital the staff should be represented on the board of management by some or all of its active members; that these members, if elected as representatives (which is the method I prefer), should be elected annually, should in no case serve for longer than two years in succession, and should be few in number, so that the lay members are always predominant. To those hospitals who have not yet tried this arrangement I would say, "Try it as soon as possible, I have seen the good results."

SOME ADMINISTRATIVE DEFECTS OF THE NATIONAL INSURANCE BILL.

BY GEORGE P. FORRESTER, F.C.S.

As is clear from a leading article in THE LANCET of Sept. 30th on the National Insurance Bill, medical and public opinion alike is a little in doubt as to the actual conditions prevailing in Germany. Therefore a consideration of the methods under which the German system is applied in practice may prove opportune, particularly in view of the absence in Great Britain of many measures upon which a scheme of this nature is naturally dependent, and which were in existence in continental countries prior to the introduction of this form of social reform.

A scheme designed directly to affect the vital interests of one-third of the entire population of the United Kingdom, and at the same time involving a fresh charge upon the national revenue in addition to the financial claims to be imposed upon an even greater proportion of the citizens of this country, represents a legislative measure fraught with far-reaching consequences which should be embarked upon only after a careful consideration of all the interests directly and indirectly involved, and after making due provision for safeguarding the legitimate claims of all persons coming within its scope. It is to be regretted that in the case of the National Insurance Bill these considerations have not prevailed more fully, for the framers of what is perhaps the greatest scheme for social reform ever presented to the British nation, a scheme fraught with vast possibilities for good and in its conception worthy of the highest praise, cannot be spared the reproach of having introduced a measure incomplete in many essential particulars. Especially they have neglected the creation of provisions absent in our country, but existent elsewhere, and of having disregarded the lessons taught by the experience of other countries. It was a comparatively easy matter to graft a measure of the nature of the National Insurance Bill on to the institutions and conditions in existence in Continental countries, and this fact has apparently been overlooked by our legislators, who in their endeavour to provide the British public with the kind of benefits enjoyed by these other countries have omitted to take into consideration the different conditions and customs prevailing at home, and have overlooked the imperative necessity of first providing similar conditions before adopting similar remedies. In their haste to rush the Bill through they avoided the inclusion of many essential administrative details, and by framing several of the clauses in vague terms they will invite disputes and frequent friction when an attempt is made to carry them into effect. This criticism applies particularly to the administration of the medical benefits, the supply of medicines, the future position of the hospitals, and the peculiar position and hardships awaiting a large section of the to-be-insured.

The unanimous and determined opposition of the medical profession which marked the introduction of the Bill affords an apt illustration of the mistake made in omitting more definite proposals for regulating the administration of the medical benefits. At the same time it shows that the framers were willing to commit the same error as their German colleagues, and instead of profiting from the lesson taught by the long years of strife that have marred the working of this scheme in Germany, and have led to the repeated occurrence of doctors' strikes in that country, they contemplate introducing practically the same, if not worse, conditions, after promising that the doctors were not to be sweated. It is the absence of any legal provision regulating the remuneration of the medical attendant that has proved the greatest source of dispute in the administration of the benefits of sickness insurance in Germany. The system of a capitation grant to be paid to the doctor represents a limited remuneration for an unlimited amount of work. The proposal first put forward by the Chancellor of the Exchequer that each doctor would receive a capitation fee amounting to 4*s*. per person insured presented no satisfactory solution of the problem; a 6*s*. capitation fee to cover the expense of drugs also did not make a favourable appeal. It must be remembered here that the Bill promises the provision of the best medical attendance, but makes no provision for the payment of special cases

requiring the assistance of specialists, such as major operations. True, in Germany the average rate of payment of the sick-club doctor works out at about 4*s.* to 5*s.* per head of the insured, or to about 12*s.* where free medical attendance is also extended to the insured person's family, but this represents his remuneration for ordinary contract practice work, including at the most small operations of minor importance.

In Great Britain there exists no standard scale of charges for medical services save the limited and unrevised Poor-law scale. In Germany the standing scale of charges, containing a minimum and maximum fee for each kind of service, becomes operative in the case of disputes arising between patient and doctor regarding the latter's fee, in the absence of any special agreement. This medical tariff also forms the basis of remuneration for professional work done on behalf of the authorities, for instance in certain classes of poor practice, prison work, &c., and is applicable to patients whose treatment is paid for by sick clubs. Generally, every German sick club, in addition to the club doctors, makes an arrangement with a number of specialists, including a surgeon, a specialist for diseases of the throat, an oculist, and so on, according to circumstances. These specialists are remunerated according to the scale of charges of the official tariff, possibly modified by private agreement to suit special cases. For years already the German doctors have been fighting to obtain a better form of remuneration than the system of capitation payment, and thanks to a splendid organisation which has not hesitated to carry into effect regular strikes of the medical attendants of sick clubs, they have succeeded in vastly improving their economic position. In many cases they have been successful in achieving their ultimate object—i.e., that the official scale of charges should alone form the basis of remuneration for sick-club work, thus substituting the capitation grant for a fixed payment for each service rendered. It would be obviously unfair to expect the British practitioner to start at a level that his German colleague has left behind, yet this would be the case were the Chancellor's scale of 4*s.* to hold good, with the important addition that in order to fulfil the promise to provide the best possible medical attendance provision would still have to be made to pay fees for services outside the province of the club doctor. If the medical benefits are to consist solely in ordinary medical treatment to the exclusion of surgical operations and special advice the German example is not being followed. Had Mr. Lloyd George fully comprehended the working of the German scheme he would have had the advantage of providing the doctors with a tangible subject for argument by embodying in the Bill a draft of a scale of charges for professional work, elaborated with the assistance of a number of doctors. The members of the profession at large would have been in a position to suggest useful amendments, and the vexed question of the free choice of doctors could have been readily solved to mutual satisfaction. It cannot be too strongly emphasised that the successful working of a scheme of this nature largely depends upon the soundness of its principles. It would be well for our legislators not to regard any apparent defects in the German scheme in the light of shedding an extra lustre on the advantages of the British measure; they should seriously consider whether these defects are not being reproduced in some different form.

In the matter of allowing medical men to do actual pharmacy work as well as to prescribe for patients, to act as physician and dispenser combined, Great Britain practically stands alone, with the sole exception of some Swiss cantons and the United States. Everywhere else the doctor writes out a prescription which the patient takes to a pharmacy to have made up, and the doctor is strictly forbidden to dispense his own medicines. Abroad the dispensing of prescriptions figures as the principal duty of the pharmacist, and it cannot be denied that the peculiar position of the "chemist" in Great Britain is largely the result of the anomaly created by depriving him so largely of his legitimate professional activity. Whilst an amendment has been carried, giving effect to the intention of the Bill, that the dispensing of medicines for the insured is to be done by pharmacists, in vain do we look for any mention of administrative details regulating the principles upon which this innovation is to be carried out. We are here again confronted by the absence of a provision existent in many continental countries, which fits in well with the provisions of a national scheme of insurance against sickness, a scale of charges for prescriptions. In Germany, Austria, Hungary, Russia, Scandinavia, Servia, and Bulgaria there exists an official tariff according to which every prescription for rich and poor alike has to be charged; in the case of club prescriptions the Government usually requires a rebate off the full charges, the pharmacist being required to grant a discount of 15 per cent., or even more, on the charges fixed by this tariff.

If the National Insurance Bill is to prove a successful measure of social reform its benefits must extend equally to all concerned, and in the public interest it is imperative to frame its provisions in such a way as to avoid on the one hand any injustice to those called upon to administer its benefits, and on the other hand to prevent any section of the community from reaping unearned profits through the same source. If the medical profession as well as the pharmacists are to participate in administering the medical benefits due precautions should be taken to ensure that each party will be in a position to fulfil his allotted share of work under satisfactory conditions. For this reason the greatest care should be taken to see that the standard of remuneration set up for both should be binding for all parties concerned. If a scale of fees for medical services is established it should be elaborated for the purpose in view and steps taken to ensure its proper application, and in the case of a national dispensing tariff this, too, should be so adapted to suit the requirements of dispensing on behalf of the insured, that its scale of charges will find a rigid application, while special precautions should be taken to prevent any unfair competition among the administrators of the benefits in order that even in its application this may prove a truly national scheme. The more evenly the whole benefits are distributed the smoother will the scheme work, and if this measure is to be enforced it cannot be too earnestly urged to provide the proper machinery in time by a greater attention and a more just appreciation of the details lacking than has hitherto been manifested.

The future position of British hospitals under the Bill is a subject of particular interest. British institutions depend for their maintenance wholly upon voluntary contributions, in distinction to continental hospitals, which are either supported by the State or municipality. In Germany, for instance, every hospital has a fixed tariff of charges varying with the class to which the patient belongs—that is to say, that a patient occupying a single room pays more than one content to share a room with another or even more persons, and all persons in a position to pay, and undergoing hospital treatment, have to comply with this rule. In the case of sick club patients, the club has to pay the hospital authorities for every patient undergoing treatment, payment being effected according to a fixed scale of charges varying according to the nature of the medical or surgical attendance required. The *per capita* rate of payment for hospital treatment in Germany amounted to 3*s.* 4*d.* in 1909; in all this item entailed a total expenditure of £2,085,325. Clause 17 of the British National Insurance Bill vaguely states that it shall be lawful for the clubs to subscribe to hospitals and other institutions in which the members receive treatment, but here again no basis of remuneration is even hinted at. Now, the Insurance Bill is a business proposition; employers and employees are forced to contribute towards the application of its provisions. On the other hand, voluntary contributions are solicited and generously given to keep up the hospitals. But as the Bill stands we may take it that the best possible medical attendance as far as hospital treatment is concerned is to be paid for out of the voluntary subscriptions of the general public, already called upon to participate in the cost of this scheme either in the capacity of employer, employee, or of a humble taxpayer. This is obviously grossly unfair, and in the first place will result in the withdrawal of subscriptions in many instances, and thus further jeopardise the existence of many institutions already in a precarious financial condition. In this case, too, a fixed basis of remuneration for patients undergoing hospital treatment would do much to place many of them on a sound foundation, and it is only necessary to apply the German figure of a payment of 3*s.* 4*d.* per head to our 14,700,000 insured to form an idea of the value of this annual contribution of £2,450,000 to institutions otherwise mainly dependent upon the public charity. The German scale of payment includes remuneration for food and attendance, medical or surgical treatment, and drugs, bandages, and dressings.

As regards the administration of the benefits, the British

Bill adopts a somewhat peculiar attitude. The insured must either become a member of a Friendly Society—i.e., of a voluntary association which has been found to deserve the appellation "approved," or if unsuccessful will be insured as a Post Office subscriber. When insurance was introduced in Germany there were no Friendly Societies equalling in importance the existing British associations, so that the few and unimportant societies could be treated as a *quantité négligeable*. The administration of the provisions of the German laws on insurance against sickness is entrusted solely to autonomous sick clubs, and beyond reserving to itself the right of supervision, the State does not interfere. These sick clubs are either local, formed to include the insured residing within a certain district or town, or establishments employing at least 50 hands are empowered to form their own sick club. In addition there exist a few associations resembling our Friendly Societies, and in some respects our trade unions, which recruit their members in all parts of the empire. A person liable to compulsory insurance and belonging to one of these is not required to enter the local club, as the German law allows all sick clubs to exist providing they comply with the legal requirements and grant their members the minimum benefits stipulated in the insurance laws. This is in marked contrast with the British point of view; in the first place, the existing Friendly Societies are required to adapt themselves to the new order of things, although in many instances their field of activity is by no means confined to the benefits set forth in the Bill, and, secondly, societies not approved of are not to be given an occasion of acting as administrators. The greatest hardship, however, will fall upon those workers for whom provision is already made, in several cases exceeding even the benefits to be enjoyed under the insurance scheme, as here they are to be compelled to comply with the letter of the law by joining some approved society or insuring through the Post Office. However, it stands to reason that the establishments which already voluntarily provide the funds for granting similar benefits will not feel disposed to pay in addition the contributions required by the new order of things, and thus we shall witness the peculiar picture of an avowedly beneficial measure bringing an actual loss to a section of its unwilling participants. To meet this objection, it would be well to permit the creation more freely of "approved" societies, without adopting the German plan which has led to the creation of no less than 23,279 sick clubs, with a total membership of 12,519,785. Latitude of this kind would enable many large establishments to continue their present satisfactory system of making proper and liberal provision for the care of their sick and disabled employees.

We should not lose sight of the fact that Great Britain is already in possession of a fully equipped organisation recently created to deal with another aspect of social reform—old age pensions. The introduction of the Insurance Bill will witness a second creation of posts for officials, and the question arises whether the machinery required to administer both statutes could not be united, in the interests of the taxpayer. It is significant that the Chancellor of the Exchequer himself estimates the cost of administration at a higher figure than is actually the case in official-ridden Germany; there the total outlay per head of the insured comes to 1*s*. 7*d* in the case of insurance against sickness, and to 1*s*. 8*d*. for insurance against invalidity, or a total expenditure of 3*s*. 3*d*. *per capita* (these two branches of insurance united in one measure in the British scheme form two distinct categories in Germany, each administered on different lines—invalidity insurance is under State, not under autonomous club, control); this still leaves a margin of 9*d*. to the good as compared with the 4*s* it is assumed will be spent on administrative expenses in Great Britain. The cost of administration in Germany is recognised as being unduly high, and the new law foresees a considerable reduction by reducing the number of existing sick clubs, and limiting the staff of officials. Presumably the quantity of officials required in Germany will be balanced by the quality to be provided in our country—as far as the salary attached to the position is concerned. It is interesting to note that in many respects the administration of the British insurance scheme will be carried out on considerably more bureaucratic and possibly less equitable lines than is actually the case in Germany, as will appear from a brief consideration of the more important fundamental principles underlying both measures.

In Germany two distinct forms of insurance are in operation; the one makes provision for sickness, and the other includes disablement and old age pensions. Both forms are strictly contributory, but the organisation and administration of each differ materially. Insurance against sickness, already mentioned, is enforced without State interference, and also without State assistance. Self-governing sick clubs are formed to meet local or other requirements, and the management of the club is vested in a board consisting of representatives of the insured and of the employers, two-thirds of which are elected by the former and the remaining one-third by the latter. The contributions depend upon the wage-earner's salary, and the total levied may not exceed 4 per cent. of the worker's earnings. Of this total one-third is contributed by the employer and the rest by the insured. For this the worker is entitled to free medical attendance, free medicines, including any appliances required, and free hospital treatment, and every care is provided to restore him to health, even to the extent of sending him, if necessary, to undergo treatment at a health resort. These benefits extend for a period of 26 weeks, and during this time he is entitled to sick pay amounting to at least half of his daily wage, or, if he undergoes treatment in a hospital, his dependents draw an amount equal to half the allowance he would be receiving were he to undergo treatment at home. The income limit for compulsory insurance is £100 a year. No distinction is made either as regards contributions or benefits in the case of women, and as the contributions are graduated according to the worker's salary the employer of unskilled labour is not compelled to pay the difference out of his own pocket, as will be the case in England with workers earning less than 2*s*. 6*d*. a day. As the sick clubs are absolutely autonomous, beyond, of course, having to comply with the provisions of the law, it follows that they are able to dispose of their surplus finances untrammelled by outside considerations, and thus it is that certain clubs in a flourishing financial state are able to go beyond the limits prescribed. Naturally, in the case of the independent sick clubs having the character of British Friendly Societies, the board of managers is composed solely of representatives of the members, and membership of one of these recognised societies complies with the compulsory insurance clause, and renders it unnecessary for the member to reinsure in another club should he change his place of work. A new law, which has raised the income limit of the compulsorily insured to £125, divides the contribution into equal shares for employer and employee alike, and effects a corresponding change in the composition of the managing boards.

It must be confessed that the German system is more equitable than the British proposal. Why should a woman be penalised for her sex in being granted a lower rate of benefits? In practice there are really more cases of women requiring assistance in illness or invalidity than of men, to mention only the widows with families, who certainly outnumber the widowers. Again, the fixed rate of contribution is not in harmony with the principle expounded by the present Government of suiting the burden of taxation to the strength of the shoulders by which it must be borne; 4*d*. a week to a man earning £3 figures differently on the budget of a household with but 18*s*. to call its own.

The second branch of industrial insurance in Germany is also contributory, and includes invalidity and old age pensions. In this the contributions are borne in equal parts by both parties, the amount being again dependent upon the wage-earner's salary, which is in this case divided into five classes, the total weekly contribution rising from 1½*d*. on salaries under £17 10*s*. to 4½*d*. on salaries over £55. In this case, however, the management of the benefits and the whole organisation lie in the hands of the Government, which contributes towards the cost of administration and supplements each invalidity or old age pension granted by a State allowance of £2 10*s*. annually. These benefits, both based on compulsory contributions, are regulated by the length of time that the applicant had been insured and by the wage class to which he belongs; the amount of an invalidity pension may therefore be anything between £5 16*s*. and £22 10*s*. per annum, while the old age pension, which becomes operative at the age of 70, ranges from £5 10*s*. to £11 10*s*. In Great Britain invalidity insurance is included with sickness insurance in a single measure, while old age pensions form a direct charge upon the national revenue; the sum granted in both cases amounts uniformly to 5*s*. a week, or a fixed annual allowance of £13, irrespective of the

recipient's former salary or of the number of years during which he has contributed towards this benefit.

In comparing social legislation at home and abroad, the Briton is nowadays prone to belittle his own institutions, and to forget that no country possesses so highly developed and well organised a system of voluntary and humanitarian associations for rendering assistance in sickness as Great Britain. The importance, as well as the financial soundness of her friendly societies and their admirable work, are universally recognised as worthy of the highest praise; they are the outcome of voluntary thrift, and a striking symbol of the sound common sense inherent in the British working classes. As a number of these societies extend their field of activity even beyond providing for their members during sickness or incapacity, it would be a mistake to seriously imperil their existence, and instead of drawing distinctions likely to lead to the extinction of many excellent bodies in establishing too narrow limits for inclusion in the magic circle of approved societies, it would be well to grant an even greater degree of autonomy in the question of administering the benefits prescribed in the Bill. On the other hand, it is evident that the State should in this case reserve itself the right to take the necessary steps to ensure an equitable application of the minimum benefits to which the insured are entitled, and at the same time to safeguard the interests of those called upon to participate in the administration of these benefits by providing certain fair standards of remuneration for services rendered. A guarantee of some kind could be required to insure the solvency of each society, somewhat on German lines. In Germany every sick club is required to accumulate a reserve fund amounting to an average year's expenditure, based on the expenses incurred during the three previous years; in addition a portion of the yearly surplus must be set aside to form a special reserve fund, to meet unforeseen contingencies such as an unprecedented incidence of sickness, epidemics, &c. The example afforded by the latter country in divorcing sickness insurance from invalidity and old-age pensions might be adopted to some advantage, if only for the resulting saving in the cost of administration. In many respects the payment of an invalidity pension is merely a clerical matter, the claim itself is based on the doctor's verdict consequent on a period of sickness. Therefore, why not relieve the approved societies of this task, a burden new to many, as hitherto several societies have limited their work to providing only for their members during sickness, or during a fixed period of incapacity, and transfer the payment of disablement benefits to the machinery already provided for the payment of old age pensions. A step of this kind would do much to simplify the administration of the other portion of the benefits provided in the scheme, already rendered unnecessarily cumbersome by the creation of two distinct classes of the insured—members of approved societies and Post Office contributors. Administrative costs have a disagreeable tendency to rise, and as they represent a totally unproductive expenditure every precaution should be taken to keep this item within the lowest possible limits.

Much positive work will have to be accomplished before the National Insurance Bill will be an efficient working measure, capable of application in practice, and while rendering tribute to Germany for the assistance afforded, the framers of this measure would do well to further study many of the foundations upon which the continental schemes are based, and after due consideration of the different conditions prevailing in our country elaborate similar provisions suitable to our peculiar requirements. Until then it cannot be regarded in the light of a carefully prepared proposal; indeed, the widespread opposition voiced against certain of its provisions proves that not sufficient care was taken to obtain the unbiased opinion, as well as the active coöperation, of members of the various interests eventually affected. Instead of attempting to rush the measure through in its present unfinished state, regardless of the chaotic conditions which may result from its vague phraseology, it would have been better to treat the Bill merely as a draft, and before submitting it for discussion invite an expression of opinion on its contents. The actual Bill presented to Parliament would embody the essential points raised in an impartial criticism by the nation at large. This course has been adopted in Germany with all measures vitally affecting the interests of a large section of the population; surely this scheme is revolutionary enough to merit a thorough discussion before the forum of the people, for whose benefit it is primarily intended, and, a more important consideration, who will ultimately be called upon to make good any financial loss resulting from a too optimistic estimation of the relationship between income and expenditure as foreseen in the Bill. A measure wholly influenced by so uncertain a factor as human health, intended to remedy any deviation from its full enjoyment, should not be introduced without a thorough consideration of its financial as well as economic aspects. To illustrate the huge sums involved in a scheme of National Insurance the principal items from the balance sheet for 1909 (the latest available official statistics) of the German insurance against sickness are appended:—

	£	Per person insured. s. d.
Total number of persons insured	12,519,785	
Contributions from employers	5,079,350	8 1½
Contributions from employees	11,448,180	18 3½
Cost of medical attendance	3,516,762	5 9
Cost of medicines, &c.	2,223,509	3 7
Sick pay to members and dependents	6,722,821	10 9¼
Payments to hospitals	2,085,325	3 4
Maternity grants	305,350	—
Cost of administration	961,306	1 7
Total reserve funds of all sick clubs	12,271,010	19 7½

MEDICINE AND THE LAW.

Hospital Witnesses and Fees at Inquests.

Dr. F. J. Waldo recently at an inquest held at the City coroner's court drew attention once more in forcible terms to the unjust provision in the Coroners Act, 1887, depriving of their fees witnesses who are medical officers of hospitals. In the case in question the medical witness asked to be relieved from waiting longer than was necessary in the coroner's court because he was due as a witness in the Clerkenwell county court. The position was thus created, and the coroner rightly called attention to it, that a medical man was compelled through being a member of the staff of a voluntary hospital to be a witness in two courts in the same day, a sufficiently onerous duty when the amount of time wasted is taken into account, as well as the importance of the issues as to which his evidence was probably essential. In one of the courts in question he would receive a fee for his attendance and in the other none. The injustice in connexion with inquests is an old cause of complaint, and the departmental committee which reported on the law relating to them in 1910 recommended that it should cease. No fresh legislation, however, has followed, but when any takes place it is probable that witnesses' fees at inquests will become the subject of rules to be made by the Home Secretary, and that fees for medical officers of institutions debarred from receiving them under the present law will be prescribed.

The Danger of Dogs not under Proper Control.

The prosecution of the owner of a dog for not keeping it under proper control, which was heard recently at the Portsmouth police court, although it failed through the inherent weakness of the case for the police, illustrates nevertheless the fact that many owners of dogs, not necessarily savage or dangerous, expose their neighbours to alarm and annoyance, and themselves incidentally to trouble and expense. The case in question had features almost of a humorous character. The animal was a Great Dane, stated to be of considerable value, and one of the chief witnesses against the character for tractability and gentleness which it had before enjoyed was a constable at whom, according to his story, it had barked and growled through the railings of a garden, where it was then safely confined, its mistress adding insult to injury by laughing at the policeman's nervousness. This incident by itself would hardly have constituted grounds for a summons, but upon another occasion a post-office messenger, when delivering a telegram at the house where the defendant lived, opened the garden gate and was the victim of an onslaught by the same dog, which evidently frightened him and possibly hurt him a little. The extent of his injuries proved to be the doubtful feature in the case. He claimed to have had some blue marks or bruises on his left arm when he returned to the post-office, and said that he was thereupon directed by "the authorities" to go to a neighbouring druggist for treatment. The druggist's assistant "cauterised the wound," that is to

say, he rubbed an ordinary caustic pencil over marks which, as the boy admitted, were not wounds at all, for there was no penetration of the skin, and whatever virtue there may have been in this operation the lad's father paid 6*d.* for its performance. We may mention here that a correspondent referring to this case informs us that druggists are very frequently asked to cauterise alleged dog-wounds, and appears to think that the marks thus produced are used to frighten dog-owners into paying compensation to avoid being made the victim of legal proceedings. Of this there was no suggestion in the case upon which we are commenting, but the druggist's assistant was not called as a witness, and as the father refused throughout to allow his son's arm to be examined by a medical man there was no evidence whatever beyond that of the boy to show whether the marks to which caustic had been applied were originally inflicted by the dog or not. In these circumstances the police may fairly be said to have instituted a prosecution upon evidence not likely to secure a conviction, and after several neighbours and friends of the defendant, including the postman, the milkman, and the dustman, had given evidence that they had found the dog quiet and harmless, the magistrates declined to make any order. They expressed, however, the opinion that the telegraph boy had told the truth, and although they attributed the dog's behaviour towards him to playfulness, they advised the defendant to control it better, lest upon some future complaint they might be obliged to deal differently with her. This appears to be an eminently sensible conclusion for the magistrates to have arrived at. If the lad's parent had been seeking to secure compensation for him in a civil court he would no doubt have called a medical witness to describe his injuries, or failing to do so would have been unable to prove that they existed. Perhaps, however, he was satisfied that the "cauterisation," at the cost of 6*d.*, of the bruises inflicted through the lad's coat was a sufficient precaution, and that "wounds" so easily and inexpensively dealt with were hardly serious enough to form the basis of litigation. However, although we may smile at the time and industry of a bench of magistrates being expended over the hearing of a charge of the nature indicated, we may also be allowed to endorse the observations made to the defendant as to the control of her dog, applying them generally rather than to her particular case. We need hardly say that the person who knows a dog to be savage towards strangers and allows it to be at large so that it may fly at passers-by on the highway, or at those who in the performance of their duties have to call at the owner's house, is guilty of a particularly cruel kind of negligence, for which he is likely to suffer financially sooner or later. There are such persons, and they are often allowed an undesirable amount of freedom from interference owing to the difficulty of proving that they know their dogs to be dangerous. There are, however, other owners who are also in their degree careless of the fear and annoyance that their animals cause, although they have no intention to neglect their duty towards their neighbours. These persons own dogs that cannot well be classed as dangerous, and in keeping them run little risk of allowing the infliction of serious injury on anyone. To take, for example, the animal made the subject of prosecution at Portsmouth. The Great Dane is known to most people as one of the largest dogs kept as pets, and its appearance is not calculated to reassure any nervous stranger with whom in play or otherwise it may desire to become familiar. As a matter of fact, but to speak generally, Great Danes are acknowledged by those acquainted with their habits to be very quiet, harmless dogs, not over-courageous or very intelligent, and certainly not, as a rule, likely to fly at anybody. Kept in confinement with insufficient exercise many big dogs become exuberantly demonstrative when released, and not everyone wishes to be the object of canine affection, still less of canine excitement and possibly of temporary irritability or nervousness. Moreover, not many people make a sufficient study of dogs' peculiarities to know whether they are savage or merely excited and over-friendly, and whether they belong to a treacherous or to a peaceful and naturally timid species. No one can expect such knowledge as this to be general or has any right to condemn those as foolish and cowardly who have not acquired it. Old ladies and children may be frightened with serious consequences by dogs who have no intention to bite them, and they have our sympathy when they are barked at and terrified by ill-disciplined animals whose owners neglect their duty to keep them in order, and thus show that they have no right to keep them at all. Offenders of this class are of both sexes, and an amount of toleration is extended to them that they do little to deserve, for the amount of trouble necessary to prevent a dog from becoming a source of annoyance is not great.

A Druggist and a Case of Poisoning.

At an inquest held recently at the City coroner's court by Dr. Waldo evidence of an incident of an unusual character was given. The deceased, a clerk in the office of a publisher and bookseller in Paternoster-row, informed the occupant of another office in the same building that he had taken spirit of salt, which he had no doubt done, and in consequence of which he soon afterwards died. This gentleman, Mr. Richard Greenacre, appears to have acted with humanity and promptitude, for he summoned police assistance and took the youth to a neighbouring druggist's shop where he asked for "an antidote," which was refused, the druggist saying apparently that it was not his duty to prescribe and that the deceased should be taken at once to a hospital. The policeman who was present asked definitely for a little chalk and water, and also meeting with refusal hurried next door, where he obtained some whitening which he used for the purpose indicated, immediately after which the electric ambulance arrived and conveyed the patient to St. Bartholomew's Hospital, where he died. Mr. A. W. Stott of St. Bartholomew's Hospital, who gave evidence, expressed the opinion with regard to what had taken place, that if chalk and water had been administered to the deceased promptly his life might possibly have been saved, but admitted that the druggist probably acted within his legal right in refusing to "prescribe." Whether it would have been a case of "prescribing" to supply something selected for the purpose by another does not seem to have been discussed. The jury expressed no opinion on the subject, but added to their verdict, which ascribed death to the self-administration of spirit of salt, a commendation of the action taken by the police constable. The druggist was placed in a difficult position, but he could have no reason to know that the policeman's diagnosis and treatment were correct.

REPORT FOR 1910 ON THE HEALTH OF MANCHESTER.

AMONG the various local contributions to the literature of Public Health the reports which reach us annually from the city of Manchester are exceptionally instructive and complete. Dealing as they do with the sanitary progress of one of our largest and most important industrial centres, these records possess a national in addition to their local interest, while they afford evidence of praiseworthy energy and public spirit on the part of the municipality. Sanitary reform in Manchester is of comparatively recent growth. By the grant of a charter in 1853 the City Corporation became responsible for the guardianship of the health of the citizens, and for the removal of the mass of adverse conditions which under the misrule of the borough reeve and constables had accumulated for years to the imminent danger of the public. A glance at the earlier reports of the first medical officer of health will suffice to show the nature and extent of the evils prevailing amidst the homes of the poor, and will give some idea of the magnitude of the task devolving on the health committee of the day for their abatement. Happily for Manchester, the reforms carried out by the corporation have generally been supported by public opinion, and under the guidance of successive medical officers of health the sanitary condition of the city has steadily improved down to the present time.

Vital Statistics.

The report before us contains the ordinary statistics respecting natality and mortality, from which it appears that the health of the community in 1910 was maintained at a high standard. The death-rate was estimated at only 15·9 per 1000 living, which is less than half the rate prevailing at the time when Manchester acquired the dignity of a city.

The subject of infantile mortality continues to receive particular attention in Manchester. "It has come to be felt," writes the medical officer (Dr. James Niven) "that if

a vigorous race is to be reared effort must be made to ensure that the care of the individual shall start at the commencement of life." Owing to the failure of the city council to adopt the Births Notification Act, Manchester is at a disadvantage in its efforts to regulate the care of infants from the earliest days of life; nevertheless, substantial progress is being achieved by the efforts of the local Midwives Supervision Committee and the Infant Life Preservation Subcommittee. At present infantile mortality is at the rate of 132 per 1000 births, against 187 per 1000, the average rate in 1891–95.

Enteric Fever.

Among topics of more than local concern Dr. Niven directs particular attention to the behaviour of enteric fever and tuberculous phthisis, both of which diseases have always caused high mortality in the city. With respect to the death-rate of enteric fever in Manchester we learn that it is higher than in England and Wales generally, and is more than twice the rate prevailing in London. And, what is of even greater importance, the mortality has not decreased so rapidly in Manchester as it has done elsewhere in this country. Possibly this is due to the persistence of some local cause, such as the consumption of infected shell-fish. The etiology of enteric fever has long been systematically studied in Manchester, and quite recently a connexion has been suspected between the ingestion of ice-cream and excessive incidence of the disease, but in the absence of exact data it has not as yet been possible to indicate the actual cause or causes of its local prevalence.

Tuberculosis.

Of all causes of death tuberculous diseases are economically the most important. In Manchester these diseases in the aggregate account for one-third of the total mortality in the span of life intervening between the fifteenth and the forty-fifth year. In the year 1910 tuberculous phthisis caused a mortality of 14·9 per 10,000 of the population, showing a reduction on the rate obtaining in 1881–85 equal to 38 per cent. From diseases of the lung other than phthisis there has also been a reduction equal to 31 per cent., so that there is no doubt as to the reality of the life saving in respect of phthisis, which is represented by a fall in the recorded death-rate from 24·2 per 10,000 in that quinquennium to 14·9 in the year under notice. The death-rate from tuberculous peritonitis and tabes mesenterica has declined since 1881–90 by 57 per cent. Other diseases of the tuberculous class have likewise declined, but in a less degree.

For many years past the campaign against tuberculosis has been prosecuted in Manchester with remarkable vigour, and recently with increased success. It will be remembered that under the Public Health (Tuberculosis) Regulations of 1908, by which notification of phthisis was introduced throughout the country, all cases of pulmonary tuberculosis occurring in Poor-law medical practice must be notified within 48 hours to the medical officer of health. Under the further regulations of the following year respecting tuberculosis in hospitals, all cases of phthisis coming under treatment in hospitals and dispensaries supported by charity must similarly be notified to the same officer. By these means the majority of phthisical cases, including those of paupers, are now compulsorily notifiable in Manchester.

The administrative measures of control now carried out in the city are set forth in this report. They include domiciliary visitation by inspectors or health visitors; the giving of advice and assistance by way of appliances; the disinfection of houses and clothing; the distribution of cautionary circulars concerning the disposal of sputa and the avoidance of unnecessary contact between the sick and the healthy. Dr. Niven holds that the provision of sanatoriums is only a part of the campaign against tuberculosis, which, in order to be effectual, must be supplemented by other preventive measures rendered possible under general notification. Public feeling has grown rapidly during the last year; and as a result the South Manchester guardians have purchased an estate of 285 acres in Wales for the treatment of their consumptive cases. Moreover, the Manchester education authority is about to establish, on an estate recently presented for the purpose, a school for the treatment of incipient cases of phthisis; and, further, a scheme of definite preventive action against tuberculosis has already been approved by the sanitary committee, and after sanction by the city council will probably be carried out at no distant date.

MEDICINE IN THE ENCYCLOPÆDIA BRITANNICA.

VII.[1]—MEDICINE.—SURGERY.—NEUROPATHOLOGY.

WE continue below our series of articles upon the medical aspects of the new edition of the Encyclopædia Britannica. Our object has been to furnish a brief review and commentary upon the various articles in the Encyclopædia which deal with medical topics, rather indicating what has been the treatment of the subjects in the Encyclopædia than suggesting that this, that, or the other might have been added or omitted. For the scope of an article in an encyclopædia must always be to large extent the matter of definite arrangement between editor and contributor. The articles on medicine and on surgery as a whole, which we have to consider among others in the issue of the later volumes, are supplementary to a number of articles scattered throughout the volume which discuss the causes, symptoms, and treatment of individual diseases.

Medicine.

The article Medicine in Vol. XVIII. of the present edition is divided into two portions. The first, which deals with the subject from the earliest times down to the year 1840, is the work of that learned historian of medicine, the late Dr. J. F. Payne, and is a revised reprint of the article written by him for former editions. The second, which deals with modern progress, is from the pen of Sir Clifford Allbutt. Dr. Payne's masterly survey of ancient and of early modern medicine has only to be well known to be rightly appreciated. To anyone who wishes to obtain a comprehensive and accurate knowledge of the history, the mistakes, the successes, and the progress of the medical profession no better short manual can be recommended than this article, although in saying this we by no means wish to minimise the value of longer treatises, such as Freind's "History of Medicine," Withington's "History of Medicine from the Earliest Times," or the works of Pagel, Le Clerc, or Neuberger.

Sir T. Clifford Allbutt, whose contribution recounts the handing on of the torch throughout the period extending from 1840 to the present day, writes, it seems to us, with acute consciousness of the vastness of his subject. And despite his great equipment he may well be so, for the discoveries, the inventions of new methods, and the modern application of old ones which have come to the fore during the past forty years alone have revolutionised both our conceptions of many diseases and our theories of treatment. And yet, with all this, the marked character of modern medicine may be said to be unity; unity in that disease is coming to be recognised as the result of varying forces operating upon a complex organism, which although it responds in apparently varying ways, yet is using fundamentally the same methods of defence, diversified, however, in accordance with the method of attack. It therefore follows that, as Sir Clifford Allbutt well says, "One of the chief lessons of the latter moiety of the nineteenth century was the unity of medicine in all its branches—a unity strengthened rather than weakened by special researches, such as those into 'medical' and 'surgical' pathology, which are daily making more manifest the absurdity of the distinction. Surgeons, physicians, oculists, laryngologists, gynæcologists, neurologists, and the rest, all are working in allotments of the same field, and combining to a common harvest." And again: "Medicine and surgery are but two aspects of one art; Pasteur shed light on both surgery and medicine, and when Lister, his disciple, penetrated into the secrets of wound fevers and septicæmia he illumined surgery and medicine alike, and, in the one sphere as in the other, coöperated in the destruction of the idea of 'essential fevers' and of inflammation as an 'entity.'"

Sir Clifford Allbutt gives a necessarily superficial review of the progress made in all departments of medicine. Omissions can of course be found. Thus he says nothing about serum therapy, and hardly anything of the principles of immunity. Again, in the section upon methods of investigation no mention is made of the various endoscopes,

[1] Articles I., II., III., IV., V., and VI. were published in THE LANCET of Feb. 25th (p. 530), March 4th (p. 609), 11th (p. 692), and 25th (p. 828), and April 1st (p. 897) and 15th (p. 1026), 1911, respectively.

such as the cystoscope or bronchoscope, while in his remarks upon the ophthalmoscope he is perhaps over-modest. For though hardly anyone has done more than he himself to link up ophthalmoscopy and medicine, he makes no allusion to his own work in this field. But taken as a whole Sir Clifford Allbutt's contribution is a worthy sequel to that of Dr. Payne, and with such a subject to write upon whatever limitations an author laid down for himself some one would be found to say that he had been too inclusive or too exclusive.

Surgery.

The article on Surgery, like that on Medicine, is divided into two sections contributed by different writers. The historical section is by Dr. C. Creighton, and that on modern practice by Mr. Edmund Owen. Of these the first portion is by far the longer, for, unlike medicine, the progress in surgery which has been made during the last forty years, great and widespreading though its effects have been, is due almost entirely to one thing—namely, Listerism.

Dr. Creighton's historical summary is of extreme interest and should be read in company with that of Dr. Payne on the medical side by all practitioners who wish for a knowledge of the history of their profession. An interesting précis is given of Susruta's practice of surgery, though as the date assigned to the work attributed to him ranges "as widely as 500 years on each side of the Christian era" the question as to whether it is one of the earliest works of the Eastern branch of the European stock on surgery must be held, as Dr. Creighton remarks, insoluble. Chinese surgery follows, and then Egyptian. Passing to Western Asia and Greece a reference is made to Homeric surgery, and an account is given of Hippocratic practice. Celsus and Galen follow and ancient surgery is brought to a close with Paulus Aegineta (A.D. 650). Throughout the dark ages—i.e., during the next 500 years—surgery was mainly kept alive by the Arabs and the Jews, although the school of Salerno sustained Hippocratic and Galenic tradition from the tenth century nearly to the thirteenth, Montpellier being the centre of Arabic medicine in Europe. In his review of mediæval surgeons Dr. Creighton curiously enough omits any mention of John Arderne (b. 1307), the well-known English surgeon, and the first in this country at any rate who acted on the sound principle that meddlesome surgery is bad surgery. Passing on to Paracelsus (1493–1541) and Paré (1510–1590) he allows full credit to both for their reforms in surgical practice, but in one place he gives the latter more than it would seem that he deserves. Dr. Creighton says: "Instead of treating gunshot wounds with hot oil according to the practice of the day, he had the temerity to trust to a simple bandage ....." If we remember rightly Paré's temerity arose from the fact that on one occasion his supply of hot oil ran out, and he had to trust to a simple dressing, on account of which he records that he passed a most uneasy night. But on finding on the following morning that his patients, over whose enforced neglect he has been making himself miserable, were much better than those who had been treated with the hot oil, he was led to substitute in future a simple dressing in the place of the irritating application. Dr. Creighton concludes his section, which may be taken to end with the middle of the nineteenth century, with a *résumé* of improvements in surgery during that period. Among others he mentions the introduction, or possibly revival, of lithotrity, but without referring to the improvement in this operation, introduced by Bigelow, by removing the débris at the time of crushing.

Mr. Edmund Owen's section upon modern surgery is, as might be expected, almost entirely confined to the rise and progress of Listerism and the gradual evolution of antisepticism into asepticism. It is an excellent essay. A short account of Bier's passive congestion treatment is given, and the article concludes with some wise words on the X rays and radium. Mr. Owen bids his readers remember that too much is not to be expected from these two forms of energy.

Neuropathology.

The article on Neuropathology, by Dr. F. W. Mott, extends to ten pages and forms, so far as such a condensed account can, an admirable introduction to this subject. A large proportion of the article is devoted to the causation of changes in the nervous system. Dr. Mott's classification of causes into "internal" and "external" has the difficulty of causing some confusion between those external or internal to the body and those external or internal to the nervous system only. A short space has been given to the numerous and important varieties of auto-intoxication of the nervous system, but all the more important conditions are glanced at, and a summary in a few words is supplied of the most recent theories. The effects of muscle-fatigue products, such as sarcolactic acid, the results of excess of uric acid, oxaluria, and glycosuria, are all noted, as well as the connexion between the graver forms of anæmia and degenerative changes in the spinal cord. To the clinician the importance of nervous symptoms indicating auto-intoxication is very great.

Incomparably the most interesting section of the article is that on poisons produced by micro-organisms, but it is short, space having been found for recent work on protozoan disease to the exclusion of other well-known conditions. The nervous sequelæ of the acute infective fevers are dismissed with an enumeration of their names, while not even that recognition, as far as we could see, is given to acute anterior poliomyelitis.

The importance of the protozoa in the production of disease in general is becoming yearly greater, and in no sphere of pathology more than in that of the nervous system. The more chronic protozoal invasions tend to produce profound changes in the nervous system characterised broadly by a formative hyperplasia of the fixed cell tissues, whether endothelial or epithelial, and there is a close similarity in the defensive reaction of the tissues to all forms of infection by protozoa. There is therefore a great advantage in studying in one article, such as that before us, the effects of the trypanosomata which have been most studied, syphilis (spirochæta pallida), sleeping sickness (trypanosoma gambiense), dourine, or *mal de coit* of horses; and to these Dr. Mott adds rabies, on the assumption that the "bodies" or cells recently described by Negri indicate a stage in the growth of a protozoon taking place within the nerve cells, comparable to the endocellular growth of the hæmatozoon malariæ within the red blood corpuscles of its host. The present position of the pathology of rabies is admirably indicated, but it is doubtful if a pathological question still *sub judice* should be introduced into an article in such a general work. It took 20 years to build up a complete knowledge of the life-history of the malarial parasite, and the general public might well wait for a few years for complete knowledge on that of rabies and variola.

Another field of recent exploration is very well surveyed. We are given here an excellent summary of the huge mass of investigation recently carried out on the cerebro-spinal fluid, which is proving of value in the diagnosis of cerebro-spinal meningitis and sleeping sickness.

Dr. Mott has attempted a difficult task in condensing into a few lines the distinction between true syphilitic lesions and the premature degenerations of nerve substance commonly known as parasyphilitic. The former are the result of the reaction, protective in character, of the tissues to the living virus, the latter are due to a bio-chemical change in the body induced by this reaction. In true syphilis there may be nervous symptoms of the gravest kind, but they are focal, selective, or limited in area; the parasyphilitic affections appear to be due to destruction of neural elements. Such breakdown of neurons is characterised, as Dr. Mott remarks, by the production of "lipoid" substances, but no hint is given as to the nature of "lipoid substances," though the author considered it necessary to explain their nature in his admirable paper on Syphilis of the Nervous System[2] before a specially informed audience. They are found in all animal and vegetable cells and fall into three groups: (1) the fatty group, such as cholesterin; (2) the nitrogenous group, such as kerasin; and (3) the lecithin group containing phosphorus and nitrogen.

It is essential in a general article to handle such a thorny question as chronic alcoholic poisoning with judgment, knowledge, and care; all three are displayed. While the importance of alcohol as a frequent cause of nervous degeneration is allowed, it is here recognised that in only 10 per cent. of the cases in the London Asylums was it the direct cause, though 20 per cent. were admitted with a history of alcoholism. Cirrhosis of the liver is so rare in asylum cases that Jane Cakebread was the only example found. This rarity of cirrhosis indicates that lapse from temperance has

[2] Proceedings of the Royal Society of Medicine, Jan. 27th, 1910.

not been of long duration in such mental cases, and is an indication of the final breakdown rather than its cause.

There is no new information to be found on the important subject of focal injuries to the brain, such as embolism, hæmorrhage, &c., but an admirably lucid sketch is given of such conditions, and of the variations in symptoms produced by variations in locality. Some excellent photographs of pathological states of the brain are appended.

The section dealing with the Microscopical Changes in Degeneration of the Neurone begins with a survey of the trophic dependence of the nerve fibre upon its cell of origin established by A. V. Waller's experiments made about 1850, and concludes by an interesting reference to the researches of the author, in conjunction with Professor W. D. Halliburton, into the chemical changes which occur during the degeneration of peripheral nerves after section.

HOSPITAL DINNERS.

St. Bartholomew's Hospital.—The annual old students' dinner was held this year as usual in the beautiful great hall of the hospital, and over 175 past and present members and guests assembled under the chairmanship of Mr. W. H. H. Jessop, senior ophthalmic surgeon to the hospital, on Oct. 2nd. Amongst those present were the treasurer, Lord Sandhurst; Sir William Church, the Presidents of the Royal Colleges of Physicians of London and Surgeons of England, the Vice-Chancellor of the University of London, the Master of the Society of Apothecaries, Sir T. Clifford Allbutt, Professor Howard Marsh, Sir Malcolm Morris, Sir James Porter, Sir William Gubbins, Sir Francis Champneys, Sir Lauder Brunton, Sir Anthony Bowlby, and the treasurer of the Foundling Hospital. The chairman, in proposing the toast of "The Hospital and Medical School," appealed for an endowment fund to ensure a living wage for lecturers. The year 1881 was the high-water-mark of prosperity of the school. Since then many new departments have been created, and work has increased in all directions, but the income has diminished. There is now a prospect that a charter for the medical school will be approved by the governors and the Privy Council, which will enable reversions to be left for the endowment of teaching and research. Mr. Jessop offered congratulations to the seven old students who have received Coronation honours, and concluded with feeling references to the great loss which the hospital had sustained by the deaths of Mr. Henry Power and Dr. Samuel Gee. Lord Sandhurst responded in a short and interesting speech, in which he touched on the National Insurance Bill and the present heavy demands upon hospital resources. Dr. Norman Moore proposed the toast of "The Guests" in the learned, witty, and graceful manner of which he is a master, and Sir William Collins, in his reply, insisted that medical men should now take an active part in public affairs. The chairman's health was proposed by Mr. W. Bruce Clarke.

Middlesex Hospital.—The annual dinner took place at the Trocadero Restaurant on Oct. 2nd. The chair was occupied by Dr. F. J. Wethered. Among those present were Prince Alexander of Teck, Sir Richard Douglas Powell, Sir James Kingston Fowler, Sir Alfred Pearce Gould, Fleet-Surgeon R. Hill, R N., Mr. James Boyton, M.P., the Mayor of Marylebone, Mr. Andrew Clark, and Mr. J. Bland-Sutton. In proposing the toast of "The Hospital and Medical School," the chairman referred feelingly to the death of Prince Francis of Teck, and eulogised the personal service rendered by him to the hospital. A large sum, he said, had been obtained through the Prince Francis of Teck Memorial Fund, but the board of the hospital was still faced by a lack of money. Prince Francis's place had been taken by his brother, Prince Alexander of Teck. The chairman congratulated Sir Alfred Pearce Gould and Sir James Kingston Fowler on their new honours. He announced that the Queen had promised to open the new cancer wing on her return from India. The new research department had been taken possession of by Dr. Lazarus-Barlow and his colleagues. A new medical ward of 15 beds was to be made by certain alterations, and to this Queen Alexandra had consented to give her name. New out-patient rooms were badly needed. Prince Alexander of Teck, in responding to the toast, thanked the chairman for his kind references to Prince Francis, and said that whatever his brother had done had been entirely actuated by a sense of public duty and a desire to be of service to his fellow creatures. He referred to the proposed scheme, which had been accepted by the weekly board and approved by King Edward's Fund, of establishing special wards for diseases of the skin, eye, and throat, and said there was every probability of this ideal being realised next year. He had lately seen enough to convince him of the value of the connexion of medical schools with hospitals even to the patients themselves, through the progress they maintained and the stimulus they afforded. A new site must be found for the out-patient department, and if some donor would provide £50,000 he would guarantee as fine an out-patient department as could be found anywhere. While the hospital expenditure last year had been exceptionally heavy the improved sanitation that had resulted from it was a permanent gain. Dr. H. Campbell Thomson, Fleet-Surgeon Hill, and Mr. E. L. Pearce Gould also replied. The Chairman of the council, in proposing a vote of thanks to Dr. Comyns Berkeley, the lecturer of the day, urged a more efficient means of communication between the weekly board and the medical staff. Sir James Kingston Fowler proposed the toast of "The Guests," and regretted the absence of Commendatore Marconi, who was to have replied. Mr. Debenham, in replying, referred to his long family connexion with the hospital. Mr. Boyton, M.P. for East Marylebone, said that in the discussion on the Insurance Bill in Parliament he had pointed out that his constituency contained about 1000 medical men. For the most part they were not of the class whose own personal interests would be affected by the Bill, so that their criticisms could not be accused of self-interest, but must be ascribed to a keen sense of what was due to their profession. Dr. D. R. C. Shepherd proposed the toast of "The Chairman," who replied. The following message was read in reply to a wireless sent to the King from the hospital in the afternoon: "Please convey to the chairman, governors, staff, and students of the Middlesex Hospital the sincere thanks of the King, Patron of the hospital, for their kind message of greeting on the occasion of the seventy-seventh anniversary of the foundation of their medical school at the hospital." In the course of the evening some excellent vocal and instrumental music was supplied.

University College Hospital.—The dinner for old and present students of the hospital was held at the Imperial Restaurant on Oct. 2nd, with Sir William Allchin in the chair. Over 120 sat down to dinner. After the loyal toasts, Sir William Allchin proposed "The Prosperity of the Medical School," and in an eloquent and thoughtful speech compared the rôle of the physician of the time of Sir William Jenner, when he was a student at the hospital, with that of the present day. The Dean, Mr. Raymond Johnson, replied in a lighter vein, expressing the gratification that all must feel at the very large increase of entries, and commending to the notice of old and present students the hospital magazine and the endowment of a bed in the hospital. The students have already collected £830 of the £1000 required for this excellent object. The speeches were interspersed with songs and instrumental music of exceptional merit.

Charing Cross Hospital.—The dinner to the past and present students was held in the evening of Oct. 2nd, in the new Adelaide Hall, at Gatti's Restaurant, opposite the hospital, under the chairmanship of Dr. Cuthbert Lockyer. The dinner was largely attended. The toast of "The Hospital and School" was proposed by the chairman, and in responding to it, the Dean, Dr. William Hunter, said that he had just received, by special messenger, a letter from H.R H. Princess Louise (Duchess of Argyll), the President of the hospital, who had opened the session and distributed the prizes in the afternoon, conveying her congratulations to the students on the reorganisation of their school, which will in every way give them greater facility and comfort to carry on their studies and research. Her Royal Highness anticipated that the zeal and enthusiasm shown by the dean and his colleagues in bringing the college to its present state of efficiency would stimulate the students to an even keener desire for success and a wish to send out the ablest men who would leave their mark on the world in the future, bringing lasting fame to the college. She wished the public would realise the great and difficult work of keeping up the efficiency with inadequate means. If they would reflect that it was all for

the benefit of the general public they would be ready to help.

St. George's Hospital.—The annual dinner of past and present students of St. George's Hospital was held at Princes Restaurant under the chairmanship of Sir Isambard Owen, Vice-Chancellor of the University of Bristol, and formerly physician to the hospital and for many years dean of the school. There was a good attendance both of the present medical staff and teachers and of the past and present students, while among the principal guests were Dr. H. A. Miers, D.Sc., Principal of the University of London, who had previously delivered the introductory address, and Professor W. D. Halliburton. Sir Isambard Owen, after the usual loyal toasts, outlined in an interesting speech the growing importance of universities to communities because of the promotion in them of the growth of the corporate spirit, and while he indicated that this spirit had always been present in the medical school at St. George's Hospital, he hoped that it would soon become manifest in all the students of the University of London. He concluded by expressing his conviction that the University of London would in the end become organised to fill the great future which it obviously should have before it. The text of Sir Isambard Owen's remarks was to wish prosperity to St. George's Hospital, and in reply Mr. A. W. West, the treasurer of the hospital, in a vigorous speech, deplored the divorce of medical schools from hospitals and criticised the action of the King Edward's Hospital Fund for London arising thereout. He spoke in a gloomy vein of the probable effects upon voluntary hospitals of the working of the National Insurance Bill, and appeared to express the sentiment of the company when he described the Bill as a most dangerous threat to the voluntary principle. Mr. H. S. Pendlebury having also replied, Dr. E. I. Spriggs proposed the health of Principal Miers in the character of the Orator of the Day. Professor Miers, in an interesting and happy speech, referred to his student days when he was a frequent visitor to St. George's Hospital, while with reference to his present charge, the University of London, he described it as possibly suffering from too much reform. Dr. Llewellyn Powell, anæsthetist to the hospital, speaking as a representative "of the most important branch of medicine," was delightfully humorous in a speech proposing the toast of "The Past and Present Students," replies to which were entrusted to Mr. C. M. Fegen and Mr. Tindall Atkinson. Mr. Clinton Dent proposed the toast of "The Chairman," whose career had for many years been run side by side with his own, as they had been students together at Cambridge, had sat for examinations simultaneously, and for many years worked together on the staff of St. George's Hospital. Sir Isambard Owen having replied, the proceedings terminated.

St. Thomas's Hospital.—The annual dinner of the past and present students was held on Oct. 3rd at the Hotel Cecil and was largely attended. Among those present were Sir Thomas Crosby, the Lord Mayor-elect, Sir Thomas Barlow, and Sir Anthony Bowlby. The chair was taken by Mr. G. H. Makins, C.B. In proposing the toast of "The Hospital and Medical School," Mr. Makins gave some interesting reminiscences extending over the past 40 years, and referred to the changes in the hospital that had taken place during his time. His reminiscences of the very remarkable staff of his time, containing sketches of Dr. Peacock, Dr. Bristowe, Dr. Ord, Dr. J. Harley, Dr. Murchison, Dr. Clapton, Sir John Simon, Mr. Sydney Jones, Mr. Croft, Sir William Mac Cormac and Mr. Mason, were delivered in a humorous vein that caused great amusement. He considered the work of the hospital and school for the past 40 years thoroughly worthy, and he referred with pride to the fact that the next Lord Mayor came from St. Thomas's. The toast was suitably acknowledged by the treasurer, Mr. Wainwright, and the Dean, Dr. H. G. Turney. Referring to Sir Thomas Crosby, whom he designated as the Grand Old Man of the dinner, Dr. Turney said that he was first medical Lord Mayor of London. On turning back to the school records for the year 1851, he found that Sir Thomas Crosby had in that year taken the several prizes for physiology, descriptive anatomy, medicine, and surgery. In 1852 he had again taken the physiology prize, and had added thereto those for forensic medicine, practical chemistry, comparative anatomy, and the Cheselden bronze medal for surgery and surgical anatomy. Others who had gained distinctions were Inspector-General Sir T. D. Gimlette; Sir H. B. Donkin; Acting Surgeon S. W. Grimslade, gold medallist at Haslar; Professor Leathes and Professor W. E. Dixon, new Fellows of the Royal Society; Dr. W. W. C. Topley, Murchison scholar and physiologist to Charing Cross Hospital; Dr. S. J. Sharkey, medical referee to the Treasury; and Mr. A. Lawson, President of the Ophthalmological Society of the United Kingdom. He also commended the cricket club and congratulated the school on securing the Inter-Hospital Sports Shield. Dr. T. D. Acland proposed the toast of "The Chairman," which was suitably acknowledged by Mr. Makins. Mr. J. H. Fisher proposed "The Health of the Guests," which was acknowledged by Sir Thomas Barlow in a manner that evoked great applause.

London Hospital.—The old students' dinner was held on Oct. 3rd at the Hotel Cecil under the chairmanship of Mr. Douro Hoare, who was supported, among others, by Mr. Otto Beit, Sir Edward Mann, Sir Frederic Eve, Sir Frederic Hewitt, Dr. Percy Kidd, and Mr. E. Hurry Fenwick. The chairman spoke of the work of the hospital and medical school, and announced with satisfaction the inauguration that day of a dental school in connexion with the London Hospital. His sharp criticism of the National Insurance Bill was endorsed by the audience. He regarded the scheme as a step towards the State control of hospitals. Mr. Fenwick proposed the health of the guests, and Sir Edward Mann and Mr. Otto Beit replied, while the toast of "The Chairman" was entrusted to Sir Frederic Eve, who deplored the general falling off in the numbers of medical students throughout the country.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 77 of the largest English towns, having an estimated population of 16,157,797 persons in the middle of this year, 7528 births and 4804 deaths were registered during the week ending Sept. 30th. The annual rate of mortality in these towns, which had steadily decreased from 21·2 to 17·0 in the five preceding weeks, further declined to 15·5 per 1000 in the week under notice. During the 13 weeks of the quarter just ended the annual death-rate in these towns averaged 16·6 per 1000, while in London during the same period the mean annual death-rate did not exceed 15·5 per 1000. The recorded annual death-rates in the 77 towns last week ranged from 5·7 in King's Norton, 8·0 in Hornsey, 8·3 in Devonport, and 8·9 in Croydon, to 22·5 in Dewsbury, 24·9 in Bury, 25·8 in St. Helens, and 28·3 in Walsall. The 4804 deaths from all causes in the 77 towns last week were no fewer than 462 less than the number returned in the previous week, and included 1056 which were referred to the principal epidemic diseases, against numbers decreasing from 2900 to 1559 in the five preceding weeks. Of these 1056 deaths from the principal epidemic diseases, 886 resulted from infantile diarrhœa, 51 from whooping-cough, 46 from diphtheria, 35 from enteric fever, 19 from measles, and 19 from scarlet fever, but not one from small-pox. The mean annual death-rate from these epidemic diseases last week was equal to 3·4 per 1000 against 5·5 and 5·0 in the two preceding weeks. The deaths of infants under 2 years of age attributed to diarrhœal diseases, which had steadily decreased from 2714 to 1377 in the five preceding weeks, further fell to 886 last week, and caused the highest annual death-rates of 6·8 in Tynemouth, 6·5 in West Hartlepool, 6·6 in Smethwick, 6·8 in Walsall, and 7·5 in Rotherham. The deaths referred to whooping-cough, which had been 55 and 61 in the two preceding weeks, fell to 51 last week, and included 13 in London, 6 in Sunderland, and 3 in Walsall. The fatal cases of diphtheria, which had been 40, 27, and 42 in the three preceding weeks, rose last week to 46; 16 deaths occurred in London and its suburban districts, 4 in Newcastle-on-Tyne, and 3 in Portsmouth. The deaths attributed to enteric fever, which had been 41 and 40 in the two preceding weeks, fell last week to 35, and included 5 in London, 4 in Liverpool, 4 in Hull, 3 in Bristol, and 3 in Bolton. The deaths referred to measles, which had decreased from 59 to 26 in the six preceding weeks, further fell last week to 19, which was the lowest number registered in any week of the current year; 4 deaths were recorded in London, 3 in Manchester, and 2 each in Stoke-on-

Trent, Wolverhampton, and Bolton. The 19 fatal cases of scarlet fever were 6 in excess of the number registered in each of the two preceding weeks, and included 4 in London, 3 in Liverpool, and 2 in Stoke-on-Trent. The number of scarlet fever patients under treatment in the Metropolitan Asylums and in the London Fever Hospital, which had increased from 1327 to 1532 in the four preceding weeks, had further risen to 1666 on Saturday last; 333 new cases of this disease were admitted to these hospitals during the week, against 217, 264, and 240 in the three preceding weeks. These hospitals also contained on Saturday last 894 cases of diphtheria, 226 of whooping-cough, 157 of enteric fever, and 83 of measles, but not one of small-pox. The 1349 deaths from all causes in London last week were 7 fewer than the number in the previous week, and included 149 which were referred to diseases of the respiratory system, against 97 and 113 in the two preceding weeks. The deaths attributed to different forms of violence in the 77 towns, which had been 169 and 160 in the two previous weeks, further fell to 134 last week, and 301 inquest cases were registered. The causes of 30, or 0·6 per cent., of the deaths registered in the 77 towns during the week under notice were not certified either by a registered medical practitioner or by a coroner after inquest. All the causes of death were duly certified last week in Leeds, Bristol, West Ham, Bradford, Newcastle-on-Tyne, Nottingham, Portsmouth, and in 57 other smaller towns. The 30 uncertified causes of death last week included 9 in Liverpool, 5 in Birmingham, 3 in Gateshead, and 2 each in St. Helens, Preston, Sheffield, and South Shields.

HEALTH OF SCOTCH TOWNS.

In eight of the principal Scotch towns, having an estimated population of 1,710,291 persons in the middle of this year, 798 births and 499 deaths were registered during the week ending Sept. 30th. The annual rate of mortality in these towns, which had been 16·4, 15·7, and 16·7 per 1000 in the three preceding weeks, declined to 15·2 in the week under notice. During the 13 weeks of the quarter just ended the annual death-rate in these Scotch towns averaged 15·2 per 1000, and was 1·4 per 1000 below the mean rate during the same period in the 77 large English towns. The annual death-rates in the Scotch towns last week ranged from 13·0 in Paisley and 13·4 in Aberdeen to 17·2 in Edinburgh and 19·0 in Dundee. The 499 deaths from all causes in the eight towns were 48 fewer than the number in the previous week, and included 78 which were referred to the principal epidemic diseases, against numbers decreasing from 134 to 95 in the four preceding weeks; of these 78 deaths, 52 resulted from diarrhœa, 13 from diphtheria, 8 from whooping-cough, 3 from scarlet fever, 1 from enteric fever, and 1 from measles, but not one from small-pox. The mean annual death-rate from these epidemic diseases in the eight towns last week was equal to 2·4 per 1000, and was 1·0 below the death-rate from the same diseases in the 77 large English towns. The deaths attributed to diarrhœal diseases, which had declined from 113 to 65 in the four preceding weeks, further fell last week to 52 and included 47 of infants under two years of age; 25 deaths were recorded in Glasgow, 9 in Dundee, 7 in Edinburgh, and 4 in Greenock. The deaths referred to diphtheria, which had been 10 and 5 in the two preceding weeks, rose to 13 last week, and included 5 in Glasgow and 2 each in Edinburgh, Aberdeen, and Perth. The 8 fatal cases of whooping-cough were 4 fewer than the number in the previous week; 3 deaths were recorded in Glasgow and 3 in Edinburgh. The 3 deaths referred to scarlet fever were equal to the average in the three preceding weeks, and included 2 in Glasgow and 1 in Edinburgh. The fatal cases of measles and enteric fever were registered in Glasgow. The deaths referred to diseases of the respiratory system, which had been 41 and 57 in the two preceding weeks, further rose to 62 last week, and were 1 in excess of the number in the corresponding week of last year. Of the 499 deaths from all causes in the eight towns last week, 181, or 36 per cent., were recorded in public institutions, and 14 deaths were attributed to different forms of violence. The causes of 9, or 1·8 per cent., of the deaths in the eight towns last week were not certified; in the 77 English towns the proportion of uncertified causes last week did not exceed 0·6 per cent.

HEALTH OF IRISH TOWNS.

In the 22 town districts of Ireland, having an estimated population of 1,149,495 persons in the middle of this year, 669 births and 396 deaths were registered during the week ending Sept. 30th. The annual rate of mortality in these towns, which had been 19·4 and 20·4 in the two preceding weeks, declined to 18·0 per 1000 in the week under notice. During the 13 weeks of the quarter just ended the annual death-rate in these Irish towns averaged 18·3 per 1000; in the 77 English towns during the same period the mean annual death-rate was equal to 16·6, whilst in the eight Scotch towns it did not exceed 15·2 per 1000. The annual death-rate last week was equal to 19·9 in Dublin (against 15·6 in London), 16·9 in Belfast, 22·5 in Cork, 19·2 in Londonderry, 23·1 in Limerick, and 11·4 in Waterford; whilst in the 16 smallest of these Irish towns the mean annual death-rate did not exceed 13·6 per 1000. The 396 deaths from all causes in the 22 Irish towns were 48 fewer than the number returned in the previous week, and included 95 which were referred to the principal epidemic diseases, against 134 and 122 in the two previous weeks; of these 95 deaths, 81 resulted from diarrhœal diseases, 6 from enteric fever, 4 from scarlet fever, 2 from whooping-cough, and 2 from diphtheria, but not one from measles or from small-pox. These 95 deaths from the principal epidemic diseases were equal to an annual death-rate of 4·3 per 1000. The mean rate from the same diseases in the 77 English towns was equal to 3·4, while in the eight Scotch towns it did not exceed 2·4 per 1000. The deaths attributed to diarrhœal diseases, which had been 117, 121, and 111 in the three preceding weeks, declined last week to 81, and included 76 of infants under two years of age; 29 deaths occurred in Dublin, 26 in Belfast, and 8 in Cork. The deaths referred to enteric fever, which had averaged 2 in the four preceding weeks, rose to 6 last week, and were all recorded in Dublin. The 4 fatal cases of scarlet fever were 1 in excess of the number in each of the two preceding weeks and included 2 deaths in Belfast. The deaths referred to whooping-cough, which had been 5 in each of the two preceding weeks, declined to 2 last week, which were registered in Dublin and Belfast respectively. The 2 fatal cases of diphtheria were equal to the average in the three preceding weeks, and were recorded in Belfast and Cork respectively. The deaths referred to diseases of the respiratory system, which had been 42 and 43 in the two preceding weeks, were 42 last week. Of the 396 deaths from all causes in the Irish towns last week, 113, or 29 per cent., were recorded in public institutions, and 9 deaths were attributed to different forms of violence. The causes of 14, or 3·5 per cent., of the deaths registered in the 22 towns last week were not certified either by a registered medical practitioner or by a coroner after inquest; the proportion of uncertified causes of death in the week under notice did not exceed 0·6 per cent. in the 77 large English towns, or 1·8 per cent. in the eight Scotch towns.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments have been notified:—Fleet-Surgeons: T. T. Jeans to the *Yarmouth*, temporary, on commissioning; and J. Whelan to the *Doris* on recommissioning. Surgeon: R. N. W. W. Biddulph to the *Pembroke*, additional, for disposal on *Doris* paying off.

ROYAL ARMY MEDICAL CORPS.

Colonel R. I. D. Hackett, principal medical officer of the Karachi Brigade, has taken up duty as Principal Medical Officer of the Abbottabad Brigade. Lieutenant-Colonel M. L. Hearn, medical inspector of recruits in the Irish Command, has been selected for appointment as Senior Medical Officer in Ceylon, embarking early in October. The War Office has approved an exchange of positions on the roster for service abroad between Lieutenant-Colonel E. A. Burnside and Lieutenant-Colonel J. C. Morgan, serving at Golden Hill and Dublin respectively. Colonel Morgan has been posted in consequence to Glasgow, with effect from Oct. 1st for duty in Charge of the Military Hospital at that station, in succession to Lieutenant-Colonel F. W. G. Gordon-Hall. Major P. J. Probyn, D.S.O., on return from a tour of duty in Hong-Kong, has been appointed

for duty at Londonderry. Major B. F. Zimmermann, who has been stationed at Topsham, has been appointed to the Medical Charge of the troops at Lancaster. Major G. St. C. Thom, who is serving in India, has taken up duty as Staff Officer of Medical Mobilisation Stores in the Second (Rawal Pindi) Division. Major W. E. Hudleston has been transferred from Parkhurst to the Military Hospital at Portsmouth. Major G. B. Carter, from Rangoon, has taken up duty at the Station Hospital, Maymyo, Burma Division. Major M. P. Corkery has been granted leave of absence home from India for eight months. Major H. S. Roch has been detailed for a tour of service in South Africa. Major J. S. Gallie has been posted to the London District and appointed Medical Officer of the Tower of London. Major A. L. A. Webb has taken up duty as Sanitary Officer at Sierra Leone, West Africa. Captain R. K. White, serving at Fermoy, has been directed to join the course of instruction for promotion to the rank of Major at the Royal Army Medical College, London, commencing on Oct. 31st next. Captain J. H. Robinson, Military Hospital, Curragh, has been placed under orders to embark for India about Oct. 11th for service with the Northern Army. Captain D. S. Skelton has been appointed to the Northern Command, England. Captain R. C. Wilmot, from the Portsmouth District, has taken up duty at Colchester as a Specialist in Ophthalmology to the district. Captain R. J. B. Buchanan has been selected for appointment as Clinical Pathologist to the Queen Alexandra Hospital at Cosham. Captain J. G. Bell has joined for duty at Seaforth. Captain J. E. H. Gatt has been transferred from Allahabad to Benares. Captain A. E. B. Wood has been posted to the Woolwich District. Captain H. B. Kelly has been appointed Specialist in Advanced Operative Surgery to the Dublin District, with headquarters at the Royal Infirmary, Phœnix Park, Dublin. Captain T. S. Dadding has taken up duty at the Military Hospital, Colchester. Lieutenant F. B. Dalgliesh, from the Station Hospital at Mhow, has been granted six months' leave of absence home from India on medical certificate. Lieutenant H. V. Stanley, from Dublin, has taken up duty at Kilbride Camp. Lieutenant T. J. Hallinan has been transferred from Cork to Kinsale. Lieutenant G. P. Taylor, from Glasgow, has joined at Irvine.

INDIAN MEDICAL SERVICE.

Lieutenant-Colonel P. Hehir has been selected to officiate as Principal Medical Officer of the Burma Division. Lieutenant-Colonel A. W. T. B. Buist has relinquished charge of the duties of superintendent of the Ambala District Jail. Lieutenant-Colonel B. C. Oldham, medical inspector of colonial emigration, has been granted 15 months' leave of absence home from India by the Home Department. The services of Lieutenant-Colonel C. F. Fearnside, senior medical officer at Fort Blair, have been replaced at the disposal of the Government of Madras. Lieutenant-Colonel P. Carr-White, agency surgeon, Madras Presidency, has been granted privilege leave of absence for 30 days. Major H. A. Forbes Knapton has been succeeded in the charge of the duties of Deputy Sanitary Commissioner of the Central Registration District, Bombay, by Captain A. F. Hamilton. Major P. Dee has been selected for appointment as First Class Civil Surgeon, Mandalay. Major P. St. C. More has relinquished charge of the Campbellpore Jail. The services of Major V. H. Roberts, medical officer in charge of plague preventive measures in the Rohtak District, have been replaced at the disposal of the Educational Department of the Government of India. Major C. F. Weinman, officiating resident physician at the Medical College Hospital, Calcutta, has been appointed a Second Class Civil Surgeon, and posted to Purnea in succession to Captain H. R. Dutton, transferred. Captain J. D. Sandes, probationer in the Chemical Examiner's Department of Bengal Presidency, has been appointed to officiate as Resident Physician at the Medical College, Calcutta, during the absence on deputation of Captain W. V. Coppinger. Captain R. B. Nicholson has been appointed to the Medical Charge of the 36th Horse. Captain H. Halliday has been posted to Lyallpur as Civil Surgeon on return to India from leave of absence. Captain W. S. Nealor has been appointed to the Substantive Medical Charge of the 123rd Outram's Rifles. Captain J. Husband has been selected for appointment as Medical Officer in Charge of the 30th Mountain Battery and the Frontier Royal Garrison Artillery. Captain H. B. Steen has taken up duty as First Resident Surgeon at the Presidency General Hospital during the absence on deputation of Captain J. W. D. Megaw. Captain W. C. Ross, deputy sanitary commissioner of the Bihar and Chota Nagpur Circle, has been granted three months' privilege leave of absence. Captain J. Masson, officiating civil surgeon of Serampore, has been appointed second resident surgeon at the Presidency General Hospital, Calcutta, in succession to Captain H. B. Foster. Lieutenant A. L. Sheppard has taken up duty as medical officer in charge of the 23rd Pioneers. Lieutenant W. O. Walker has been selected for appointment as medical officer in charge of the 27th Light Cavalry.

DEATHS IN THE SERVICES.

Deputy-Surgeon-General Sir Henry Jules Blanc, K.C.V.O., aged 80 years, at Paris on Sept. 30th. He served in the China War, 1860–62, as assistant surgeon with the Jagir Corps. In 1866–68 he accompanied a mission to Abyssinia on special duty, and was taken prisoner and kept in chains for nearly two years by the Emperor Theodore. He subsequently received the thanks of the British Government, and was awarded a gratuity of £2000 with the medal. Later he joined the British troops and was present at the storming and capture of Magdala (medal). After acting as senior surgeon and professor of surgery at the Grant Medical College, Bombay, he retired in 1887. He was created a K.C.V.O. in 1901.—Surgeon-Major John Raby, retired pay, late Bombay Medical Service, on Sept. 22nd, at Devonia, Paignton, aged 70. He joined the Bombay Medical Service as assistant surgeon in 1866, and in the following year accompanied the Bombay troops to Abyssinia, and took part in the expedition under Sir R. Napier. He retired in 1879.

VENTILATION IN THE NAVY.

The *Naval and Military Record* of Sept. 27th published a letter purporting to come from a chief petty officer, the highest grade on the lower deck, complaining of the bad ventilation of the newest ships in the navy and of the consequent wetness of their decks all through the winter, and asking that some officer should be directly responsible for the proper and unobstructed use of the ventilating machinery on board at all times. The new principal medical officers of the fleets have here at once employment worthy of their position. We shall expect to hear quite a different tale next winter, for those officers know as well as we that "a dry ship is a healthy ship," and they now have power to make their representations to the highest authorities.

NAVAL MEDICAL DINNER.

It is proposed to have the naval medical dinner in London about the third week in November, and further details will be given when the date is decided upon.

THE HEAD-DRESS OF THE ARMY.

The Army Council has decided that the service dress-cap is to be the head-dress for wear by all ranks in the field in temperate climates for all branches of the Expeditionary Force. The present pattern of service dress-cap is a modification of what used to be known as the "Brodrick" cap with the addition of a peak. It is a comfortable and in many ways a very suitable cap, but it does not give any protection to either the head or neck from the sun or from missiles such as stones when troops are on strike duty. A good head-dress for troops should provide protection to the head and eyes from the heat and glare of the sun, should be waterproof and afford little resistance to wind, should be possible of ventilation, light, durable, and comfortable, and should not press unduly on the scalp. The solution of these difficulties remains to be effected, as it is almost impossible to combine all the above advantages in a head-dress appropriate to all climates and at the same time suitable for peace and war.

ENTERIC FEVER AT WHITTINGTON BARRACKS.

The *Times* states that two deaths have taken place as the result of the outbreak of enteric fever amongst the men of the 2nd Battalion Royal Warwickshire Regiment, who are stationed at Whittington Barracks, Lichfield.

THE JAPANESE NAVAL MEDICAL DEPARTMENT IN THE RUSSO-JAPANESE WAR.

THE second instalment[1] of the translation of the Japanese naval medical report of the late war by Dr. Chemin, staff-

[1] The first appeared in THE LANCET of Sept. 23rd, p. 914.

surgeon in the French navy, appears in the September number of the *Archives de Médecine et Pharmacie Navales*. It should be read by every naval surgeon. This month he recounts the medical experiences associated with the sinking of ships by submarine mines, and rules are given for dealing with such emergencies. The less freeboard a rescuing boat has the better, for to get a half-drowned man over the high side of a big boat like a launch is a matter of great difficulty and takes up much time, time which is then very valuable, for the more quickly each man can be got on board the more men will be rescued. When a ship is sinking, men who jump into the sea, especially in cold weather, should not remove their clothing, for the air within it is only gradually displaced by water, and until that occurs it goes on acting as a non-conductor of heat, and so for the time delays and diminishes chill and shock. A man in the water should not try to swim except for a definite purpose, but be content to float, and be satisfied if he can just keep his mouth above water. The best life-buoy is a lashed-up hammock; it does not turn over and over like a cask, and there is always the lashing to hang on to; and a man, especially if exhausted, should never let go of his hammock, however near the boat he is, till his rescuers have hold of him. When a man has been rescued get his wet clothes off, wrap him in dry blankets (have some ready in the boats), give him a hot drink, and lay him down in a warm part of the ship (flats or ammunition passage). When the *Hatsuse* (three surgeons and seven nurses she had) was lost, 340 men were taken out of the water by boats from other ships. It was noted that when the boats came no man asked for help for himself, but they all eagerly hailed their rescuers, telling them where to find the officers.

"THE MILITARY SURGEON."

The *Military Surgeon* (Washington, D.C.) for September has as its first paper an article on Cholera by Dr. J. M. Hurley, who served through the Civil War and several cholera epidemics. He sketches the history of the cholera epidemics of Canada and the United States in detail and gives an excellent clinical account of the disease. He notices particularly the movements which occur from post-mortem contractions of muscles. He has known them to continue even for 24 hours. They often make watchers doubtful if the patient be really yet dead. Major J. H. Ford, Medical Corps, U.S.A., declares that in the manœuvre camp at Galveston 4000 men, all inoculated against typhoid fever, had not one case of the disease during the three months of the camp, while the incidence on 4000 persons living in the closely adjacent Galveston was in the same period 19. The most prevalent diseases were venereal; fortnightly inspections were made and prophylactic packets were issued, but in insufficient numbers. Captain E. B. Vedder, of the same corps, recommends ipecacuanha with the emetine left in for the cure of amœbic dysentery. The official U.S.A. army regulations for the use of salvarsan by intravenous injection and for antityphoid inoculation are given.

UNIVERSITY OF LONDON.—Professor E. A. Minchin, M.A., professor of protozoology in the University, will give a special course of about 15 lectures on "Trypanosomes and Allied Flagellates" at the Lister Institute of Preventive Medicine at 5 P.M. on Tuesdays and Fridays during the second term (January to March, 1912). These lectures, which are free, will be addressed to honours B.Sc. students and to medical men, and will be followed by exhibits of preparations as occasion requires. Further details will be published at a later date. A course of four lectures on "The History of Plague" will be given by Dr. Charles Creighton at the University, South Kensington, on Fridays, Oct. 20th, 27th, Nov. 3rd and 10th, at 4 P.M. Lecture I. will deal with "The Great Plagues of the Sixth and Fourteenth Centuries"; Lecture II. with "The Breeding-places of Plague"; Lecture III. with the "History of Plague in India"; and Lecture IV. with the "History of Preventive Measures and their Theory." A course of eight lectures on "The Manipulation and Theory of the Microscope" will be given by Mr. J. E. Barnard, F.R.M.S., at King's College, on Wednesdays, at 5 P.M., beginning on Oct. 11th. The lectures are addressed to advanced students of the University and to others interested in the subject. Admission free, without ticket.

Correspondence.

"Audi alteram partem."

THE NATIONAL INSURANCE BILL.

To the Editor of THE LANCET.

SIR,—May I be allowed to refer to a few of the points raised by Mr. Albert Benthall in his letter published in THE LANCET of to-day's date. To deal with his second paragraph. When and where has the Chancellor offered "to grant a very much higher scale than at present in force in contract practice"? The ordinary scale is about 4*s.* per head per annum *for examined lives*. The Chancellor said in Parliament that 8*s.* 6*d.* was a most extraordinary demand; he also intimated that £4,500,000 would be set aside to provide medical aid for 15,000,000 people. This works out at 6*s.* per head, and may be presumed to include drugs, appliances, serums, vaccines, &c. These 15,000,000 will include all lives, not examined, even chronic invalids so long as they are not too bad to do some kind of work. In my opinion the present club pay is the better bargain of the two. I can nowhere find evidence that the Chancellor's "offer to relieve the profession of the expense of drugs" has been declined. On the contrary, Clause 14 (5) provides for dispensing as a separate charge from treatment.

I quite agree that the neglect to adequately safeguard club doctors, the leaving the whole matter of payment an open question, the constitution of health committees, and their substitution for Friendly Societies, are very weak points in an already weak position. I would go farther and say that in my opinion the six-point programme is in itself a confession of weakness; a compromise which has been still further compromised. I gather from the tone of his letter that Mr. Benthall thinks gravely of the present position of the profession. So do I. I think that the opening rounds of the fight have left us in a worse position than before. I think, apparently with Mr. Benthall, that our present tactics will not carry us to victory. But when Mr. Benthall comes to the remedy I am bound to say that I consider it worse than the disease.

Chief among Mr. Benthall's arguments is the perfectly true one that under the new *régime* we shall be at the mercy of Friendly Societies, lay committees, work-people's representatives, *et hoc genus omne*. His remedy is that we should all become State servants, at the mercy of Parliamentary officials, under the absolute control of a Government which, whatever colour it may be, depends for its life on the votes of the very classes we would escape from. The justice of our plea for relief from Friendly Society control was recognised in Parliament by the vote, 387–15. The expediency of conciliating these societies was proved by the Harmsworth amendment, accepted by Government without demur. And it will always be so. The rights of thousands will weigh as nothing in the eyes of any Government when compared with the votes of millions. Our servitude will be far greater as State servants than as club doctors. A State servant is a dumb, muzzled servant, who cannot speak his mind on any public question; he has no politics; he is no longer a citizen; his independence is gone. I think that the establishment of a State medical service would be a calamity for the public and the profession. But Mr. Benthall says that this is the only alternative. Here again I must differ. The alternative to club slavery and to State slavery is independence. Abolition of contract practice is the only logical outcome of the frequent complaints uttered against contract practice by doctors, Poor-law Commission, Chancellor, &c.

The worker up to now has been a poor man whom we have readily recognised as being unable to pay adequate fees, and whom we have been glad to meet much more than half way by attendance at a nominal sum. As a State beneficiary he will be a rich man, and therefore in a position to pay us proper fees. For many years we doctors have been underwriting the insurance risk, because the man has been poor. Now the State should take the burden from our shoulders and undertake their own insurance risk.

Mr. Benthall asks: "Is it possible to secure the best medical service to the people without undue expense to the State, and with honour and sufficient emoluments to medical

men?" My answer is, Yes, it is possible, but not with a State service, which will probably not be efficient, nor will it be honourable of us to give up our birthright of independence. The highest efficiency of medical practice is an adequately paid private practice. If the highest efficiency be gained the expense will not be undue. If the State wants the highest efficiency, the State, not the profession, must pay for it.

It is possible to get out of the present imbroglio with honour, to secure an efficient service to the workers, and to secure acceptable terms of service for the profession, but, in my opinion, this can only be done by adopting the policy of "payment per attendance." This policy has been endorsed by an immense number of practitioners in this country, and only now the German insurance doctors have given notice that they have had enough contract practice and will not have any more of it. Can we not profit by the experience of our German brothers? Can we not say this contract system stands condemned in this country and in Germany, and we will not take service under it? Our terms are: No insurance risk and payment per attendance. If you do not like them you can leave them.

I am, Sir, yours faithfully,

H. F. DEVIS.

Bristol, Sept. 30th, 1911.

To the Editor of THE LANCET.

SIR,—I have read with great interest Mr. Benthall's letter in your last issue. With most of his remarks I am in perfect agreement, and I think he shows clearly the disastrous effect the present Bill is likely to have on the future of the profession. Although personally a strong opponent of Friendly Society control, there is much in his contention that control by the Local Health Committees may not be one whit better, but only Friendly Society control "writ large." With regard to a "strike" being "an insult to the profession, and impracticable," unless Mr. Benthall has in his mind a medical strike on all fours with one of the recent industrial strikes, I cannot agree with him. No strike of that nature has ever been contemplated. There would be nothing impracticable in the great body of the profession refusing to undertake any of the medical duties laid down by the Bill, if passed in opposition to its demands. Unless the British Medical Association is to stultify itself, some such step must be taken if the requirements of our profession are surrendered to the clamours of the Friendly Societies.

With regard to a State Medical Service, that is a matter for further consideration, and there is, in my opinion, another alternative, which would still leave open the question of the formation of such a service. In Ireland the Irish Parliamentary Party is going to demand that medical benefits be excluded from the Bill. It is said the profession in Ireland is opposed to this; but if any such policy could be carried out here I cannot help thinking that it would be heartily welcomed by the great majority of the profession. Whatever evils exist now, few, I think, would wish to change the present state for the uninviting prospect offered by this Bill or its probable developments. The evils instanced by Mr. Benthall are appalling enough, and he does not mention the profound blow that must be given to the welfare of the profession, in the practical absence of an income-limit, by changing the greater part of the present private practice into club practice. A State Medical Service for those unable to pay, which might after all be only a reformed Poor-law Medical Service, would be a small evil compared with such a revolution. With the Friendly Societies and medical profession diametrically opposed on fundamental principles, which do not admit of compromise, it is next to impossible to expect that any system of medical benefits can be usefully included in the Bill, and the best alternative is that the Bill —if it is to pass at all—should restrict itself, as I believe was the original intention of its promoters, to benefits other than medical.

I am, Sir, yours faithfully,

London, Sept. 30th, 1911. MAJOR GREENWOOD.

To the Editor of THE LANCET.

SIR,—I am in a good deal of agreement with Mr. Benthall's remarks in your current issue regarding the minimum capitation grant; but the profession seemed to be almost unanimous in excluding any amendment to the Bill for effecting this purpose. For instance, at a meeting of the local profession here I brought this matter forward but failed to find a seconder for my proposal. I do not, however, remember to have read any speech or statement by the Chancellor in which he offered a "much higher scale" than the present average. No definite minimum scale was laid down in introducing the measure; and afterwards on many occasions, especially at the special meeting of the British Medical Association, he advised the doctors not to try for the insertion of such a provision in the Bill. Rightly or wrongly, his desire seemed to be that we would not be tied as to our future action, and that by our own solid and unbroken combination we would be able to safeguard ourselves as regards our duties and remuneration. Personally, I think that Mr. Lloyd George, since he properly understood representative medical opinion, has had a sincere desire to do us justice, and that the more satisfactory and fair our payment eventually would be the better he would like it. But the profession does not seem to see it in this light. Again, Mr. Benthall raises the question of the "free choice of doctor." But, at every branch meeting of the British Medical Association, to which all practitioners in the area, members and non-members, were invited, this provision was carried with practical unanimity. If the views of the profession are thus put forward and afterwards repudiated, how can any statesman enter into negotiations with us in the future? It is unfair to assume that the interests of those holding club appointments have not been properly considered.

Now, when a comparison is instituted between the present medical attendance under the Friendly Societies and that contemplated under the National Insurance Bill, and a choice asked to be made between the two, I have little doubt on which side the bulk of the general practitioners would be found. Nor can I agree with Mr. Benthall that the control of the Local Health Committees, for which the united profession has asked, would have nearly as many objectionable features as that of the Friendly Societies. On this head, indeed, no acknowledgment is made of the Chancellor's repeated promises to give the profession increased representation on the Insurance Commission, the Advisory Committee, and the Local Health Committees; nor is mention made of the Local Medical Committees which it is proposed to set up in each area, and which will directly represent the medical men on the panel. Fair-play demands that these concessions should be acknowledged. It is, of course, true that the Friendly Societies may have a majority on the Health Committees, but even then much of the control of the doctors will be carried out by well-defined rules made by the Insurance Commissioners. But even from the point of view of the general practitioner's interests it would be better for the Friendly Societies to have such a majority than the public health authorities who, from the introduction of the Bill, have wished to get the service into their hands and appoint whole-time medical officers to the great detriment of the interests of the general practitioners.

We have thus a medical service with doctors discharging "very responsible public duties," strictly regulated by the rules of the Insurance Commissioners, guarded by the ethical rules of the Local Medical Committee, and with the insurance doctor more independent, paid a better capitation fee, and having more security of tenure. And such being the case it is difficult to understand why malingering should increase; and from my own experience of nearly 25 years' work, including club and other forms of practices solely amongst the working-classes, I hold that a much greater check will be kept on these evil practices under the National Insurance Act than under the Friendly Societies.

In his letter Mr. Benthall pleads for a State medical service, and certainly this might have its advantages for the present generation of medical practitioners; but I think such a system is much more likely to be evolved from the medical service under the National Insurance scheme than to be immediately proposed by any practical statesman, taking into account present experiences. Lastly, as Mr. Benthall has entered a plea for the present club doctors, I hope I may be allowed to plead for those practitioners who believe in the beneficence of the amended National Insurance Bill. More than three-fourths of the work under the Act will fall to the lot of those practitioners who practise in the great industrial and working-class centres. To those, then, threatened on one flank by ever-increasing hospital abuse and on the other flank by Socialistic Poor-law reform and an extension of the present club system, and daily having their incomes reduced to almost vanishing-point from other causes too numerous to enumerate, I think the Bill will bring an enhanced income and substitute security for precariousness. It

is exactly those struggling practitioners, before whom Mr. Benthall would not spread temptation, who will be made more secure financially, and therefore more independent to discharge their duties under the Act. It is only doing bare justice to the heads of the British Medical Association to say that, since the introduction of the Bill, their policy has been to get from this measure the greatest good for the greatest number; but whilst I admit this, I believe that criticism of the Bill, both lay and medical, has been often one-sided and unfair, and frequently of the blind-alley kind. No attempt seems to have been made to consider the Bill in an impartial, calm, and reasoned manner, and from the point of view of the present position of the general practitioners who, as I have stated above, will attend the largest number of patients under the scheme. No acknowledgment is made of the fact, admitted by hospital managers, that the out-patient departments of the hospitals will be depleted by reason of the number of patients who will then be the paying patients of the insurance doctor instead of the recipients of charity; or of the number of present parish patients who will in the future be placed under the insurance scheme. And then we are told nothing, by those critics, of the one or two millions of money for maternity benefit which may, if we wish, go into our pockets.

And are we to forget the "Battle of the Clubs" (so graphically described in THE LANCET), or, to come to questions more immediately connected with the present crisis, are we to leave out of count the undoubted fact that in any case, even if the Bill is lost, there will be a large accession in numbers of the members of the Friendly Societies, partly due to the increased business stimulus given by the discussions on the Bill, but, even more due to the fact that the industrial insurance companies, the dividing and collecting societies, &c., may, Bill or no Bill, start Friendly Society work on their own account, safeguarding themselves, if necessary, from any hostile action of the General Medical Council by the adoption of a system based somewhat on the lines of the National Deposit Friendly Society. By this means it is said that, including women and children, the number of club patients in the kingdom will soon reach a total of 10 or 12 millions—a figure nearly approaching that contemplated under the Insurance Bill. And who will say that the present club doctors and others will not continue to give attendance to those new members in the future as they have attended the old members in the past, especially when we are informed that even recently men were working against each other to secure a club appointment with a 3*s.* 6*d.* per annum capitation fee?

In conclusion, I am fully aware that many medical men would kill the Bill and use some polite word about the consequences. But I will not be "in at the death," because I believe in the scheme, and I think the profession will make a huge blunder if by unreflective action this disastrous result is brought about.

I am, Sir, yours faithfully,

Mile End-road, E., Oct. 2nd, 1911. M. S. HARFORD.

To the Editor of THE LANCET.

SIR,—From the almost universal dissatisfaction expressed regarding the Insurance Bill, it is now evident that failing its withdrawal it will secure at most a reluctant acceptance in the House of Commons. The present is therefore, I think, an opportune moment for the profession to come forward and proffer its assistance in framing a measure which would be in its best and truest sense a State Medical Service. Each of the three parties concerned—the State, the public, and the medical profession—are now cognisant of each other's difficulties as well as of the advantages and disadvantages in such a scheme; indeed, the ignorance of Mr. Lloyd George on these matters was the primary cause of the present *impasse*.

Should such a proposition be accepted by those concerned, the medical element in such a conclave needs some guarding. Grateful indeed as we are to the British Medical Association for its action in the later negotiations with the Government, there is a feeling amongst many of us that in the earlier stages it was the *vis a tergo* of the justly irate general practitioner that saved the situation by strengthening the resistance of that Association.

Following the recent precedent of a Royal Commission on Railway Disputes the Chancellor of the Exchequer may perhaps see his way to appointing a commission comprised of delegates from Friendly, Dividing, and Insurance Societies, hospital officers, chemists, and, last, but not least important, general practitioners, who, after all, are the mainspring of the machine. While maintaining those points which we have hitherto deemed vital to our existence, I think in many other directions from no other source could Mr. George obtain more valuable help and wider experience in making straight the way to the loyal and lasting acceptance by the entire medical profession of a very necessary measure of social improvement.

I am, Sir, yours faithfully,

Norbury, S.W., Oct. 3rd, 1911. FRANCIS MURPHY.

THE HUNTERIAN SOCIETY'S MEDAL.

To the Editor of THE LANCET.

SIR,—The Hunterian Society awards annually a silver medal for the best essay by a general practitioner embodying the results of his own observations. May we remind intending candidates that the last day for the present competition is Dec. 31st, 1911. Any further particulars may be obtained from us. Thanking you,

We are, Sir, yours faithfully,

A. P. GIBBONS,
A. C. JORDAN, } Honorary Secretaries.

17, Finsbury-circus, E.C., Oct. 3rd, 1911.

THE THERAPEUTICS OF SCARLET RED.

To the Editor of THE LANCET.

SIR,—A recent search in its literature inclined me to think that scarlet red was almost unknown in this country, and your annotation on its properties may possibly bring it into commoner use. My introduction to it was through a letter from Mr. J. E. R. McDonagh, which appeared in your columns on Nov. 27th, 1909, and suggested its employment for ulcers. I have had no opportunity of trying it in this condition, although since April last I have prescribed it in almost 80 cases in this hospital. In the great majority of these it was given for intertrigo of the ears or of the napkin area, and certainly seemed to produce marked improvement in even 24 hours. One case in which I used it had an irregular raw area (measuring about 10 by 6 cm.) on the scalp over the left parietal bone due to a burn. This was treated with scarlet red and in 19 days was completely covered with smooth, supple skin, on patches of which hair is now growing. To set off such a satisfactory result I may mention one case of suppurating hip-joint disease the wound of which had completely broken down, and one case of fæcal fistula with much skin irritation. In both these scarlet red failed, and in the latter made the condition worse in the short time it was applied. This emphasises the necessity of having the surface clean, as you quote from Schmieden. My experience is limited to one form—that procurable from Zimmermann. I have noticed that after a time a gritty sediment forms in the preparation. This seems to show that it is preferable to make it up frequently in small quantities at a time.

I am, Sir, yours faithfully,

Park Hospital, Hither Green, Lewisham, S.E., Sept. 30th, 1911. JAMES RAE.

UNPAID MEDICAL ASSISTANCE ON BOARD SHIP.

To the Editor of THE LANCET.

SIR,—I should like an expression of opinion on the following. On board the steamer in which, as a passenger and not as a medical man, I recently returned to England, the surgeon sought my advice as to a stoker who had been in hospital some days. I at once volunteered to see the case and advised immediate surgical intervention. The surgeon then asked me if I would give the anæsthetic. I did so, and intimated that, while quite willing to help a *confrère* on a point of diagnosis, I considered I was entitled to a fee from the shipping company for the administration of the anæsthetic.

The surgeon was in agreement with my view and promised to arrange the matter with the captain of the ship. The latter, however, ridiculed the idea, and on my speaking to him stated that the services were rendered to the ship's surgeon personally and not to the company. He sent for the surgeon, and on his reply that he had asked for my services

said: "Then you must pay the fee." The captain's view, as he stated it, was that he or the mate could have given the anæsthetic. The manager of the company in London takes the same view and refuses remuneration. The surgeon himself offered me a fee, which, of course, I declined to accept.

The question arises: Can a ship surgeon pledge the credit of his company to secure the services of a qualified anæsthetist for urgent operations on board?

I am, Sir, yours faithfully,

London, Sept. 26th, 1911. C. J. S.

*** We cannot say what view would be taken in a court of law of this claim. That a ship's surgeon ought to be able to provide himself with the services of an anæsthetist, if one is available, without having to pay the fee personally is clear. It is equally clear that no passenger, because he happens to be a qualified medical man, ought to be allowed to give anæsthetics to a steamship company's servant without remuneration. The lesson is that medical passengers asked to assist in an operation on board ship, the patient being one of the ship's company, should state their fee to the captain and learn that they will receive it. By the way, what would happen if a captain or mate administered chloroform to a stoker and killed him, having refused to pledge the company to pay for the help of a qualified medical man? The course of modern litigation suggests that the company might have to pay say £200 to a widow instead of 2 guineas to a practitioner.—ED. L.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

The British Hospitals Association and the National Insurance Bill.

THE second annual conference was held in the Town-hall, Manchester, on Sept. 28th and 29th. Of the three subjects set down for discussion by far the most important was the question of the National Insurance Bill and its probable practical effects upon the voluntary hospitals and their work. The whole of the morning of the first day's meeting was devoted to this subject.

The chairman of the conference, Sir William Cobbett, who is also chairman of the infirmary board, delivered a long and closely reasoned address. He said that the effect of the Bill in the main would be financial. It had been suggested that it would make a considerable difference to the amount of work that hospitals would have to do, and that it would curtail the work of the out-patient department. It seemed safe to assume at present that the work of the out-patient department, though it might be diminished to some extent, would not be enormously affected. All those persons who were at present treated as in-patients would hereafter be insured persons, and all insured persons would be eligible as in-patients. On the other hand, there seemed no reason for supposing that in-patient work would be diminished, and the in-patient work was the expensive work of hospitals; therefore he thought that the Insurance Bill would not diminish the work of the hospitals in future, and their expenditure would be just as large. As to the effect of the Bill on the finances of the hospitals, it would lessen the amount of their subscriptions through the taxation for an allied purpose of the people who at present voluntarily supported them. He controverted the opinion of the Chancellor of the Exchequer that the Bill did not touch the hospitals, but designedly left them alone. The Chancellor, he said, had tapped and diverted two of the sources from which voluntary hospitals obtained a very large proportion of their donations and subscriptions—the working man and the employer, and it did not follow that the opinion which the Chancellor had formed was the correct one. As to the effect on subscriptions, almost without exception the opinion of the administrators of hospitals was that the Bill must necessarily have a serious and injurious effect on the finances of hospitals. Was it not a reasonable thing for hospitals to ask that some precautionary provision should be inserted in the Bill, so that in two or three or four years the hospitals should not be found in a crippled condition, so that they should not have to close their doors? The association had proposed to the Chancellor that he should amend his Bill in such a way that the voluntary hospitals should receive proper payment in respect of each in-patient treated within their walls.

Mr. Lupton, chairman of the Leeds Infirmary, discussed the effects of the Bill on the hospital system itself, as apart from the effects of the Bill on the finances of the hospitals. The great hospitals were in the great centres of population, and it was only in such centres that sufficient pecuniary assistance could be obtained for their institution, and where men qualified to devote themselves to the highest type of medical work could afford to group themselves. If they were to retain the great benefits of the present voluntary system, they must take care that if subventions from the public purse proved necessary such subventions in the case of the larger hospitals should come, not from the funds of the localities where such hospitals were situated, but from the National Exchequer. If the hospitals were municipally subsidised and controlled the tendency would be to close them to people living outside the municipality. In that case he failed to see how such help was to reach the people who lived in remote villages and hamlets.

Dr. D. J. Mackintosh, superintendent of the Western Infirmary, Glasgow, suggested that the Bill might be amended to prevent anyone whose income was over the insurance limit from admission to a voluntary hospital, and by making provision in the Bill for the Insurance Commissioners to defray the cost of treatment of each person admitted to hospital. The alternatives, he said, were for the Government to make such amendments as would not only safeguard the voluntary hospitals but render them increasingly efficient, yet less liable to abuse, or for the State to take them over, finance them, and see them carried on.

Amongst the other speakers were Mr. Howard J. Collins, of the General Hospital, Birmingham, and Mr. J. C. Buchanan, secretary of the Metropolitan Hospital, London, who urged that the British Hospitals Association should combine with the British Medical Association to draw up a scheme which should define the work that the hospitals would do best in relation to other agencies, and thus assist the Government to carry out its repeatedly expressed intention of maintaining the voluntary system. Sir Henry Burdett urged that more time should be allowed the country for the consideration of the Bill. He strongly favoured the Bill. He was of opinion that it would be a grave peril and a bitter wrong to substitute State aid for the voluntary system. The financial effect of handing voluntary hospitals to the control of the State would mean a difference of 8*s.* 6½*d.* per head of the population. He desired to see Clause 15 of the Bill, which provided for sanatorium benefit, altered to provide for hospital benefit.

On the second day of the meeting the following resolution was passed:—

That this association of hospital managers and administrators is convinced that the National Insurance Bill, if passed in its present form, will seriously prejudice hospitals all over the country, not only financially, but in their relation to the medical profession, and unites in calling on the Government so to amend the Bill that the continued existence of voluntary hospitals may be safeguarded financially, and their efficiency as curative institutions and schools of medicine may be maintained and developed.

Papers were contributed by Mr. Charles Hopkinson on the Distribution of Hospital Saturday and Sunday Funds, and by Dr. Ernest S. Reynolds on the Representation of Honorary Medical Staffs upon Boards of Management of Voluntary Hospitals.[1] The latter urged that the purely business affairs of a hospital should be left entirely to the lay members. Retired members of the medical staff should not act as representatives. The representatives should be relatively few in number, so as to be in a minority. They should attend regularly, should not serve for more than two years in succession, and their function should be to advise or to explain on matters relating to the well-being and treatment of patients, or to the teaching of students. The council of the association was invited to hold the next meeting of the association in Birmingham.

Report of the Medical Officer of the Grammar School.

The annual report to the governors of the Manchester Grammar School by their medical officer, Dr. Alfred A.

[1] Dr. Reynolds's paper is published in full at p. 1028 of the present issue.

Mumford, for the year ending July, 1911, gives as complete a record as possible of the facts of physical growth. These facts are compared with progress in the school. The comparison is placed before the special form masters responsible for particular groups of boys. Each boy has a card on which the details are entered. Actual physical measurements have been efficiently carried out in the school since 1881. Every new boy is medically examined on entry as to eyesight, hearing, teeth, past and present states of health, condition of lungs and heart. Comparing the physical development during the last five years with that of a generation ago—i.e., during the period 1881–86—there has been a remarkable gain in nearly all directions, especially as regards height and weight, amounting to more than one inch in height between the ages of 13 and 16, and to an average increase of more than 4 lb. in weight. At the age of 16 the boys are 1½ inches taller and 8 pounds heavier than a generation ago. The improvement is less marked at 17 and 18 years of age, and disappears in those who stay till 19. These calculations are based on 6000 measurements. This remarkable change has more than school significance and has many causes, chief among them being the steady diminution or postponement of early infectious diseases in childhood, due to the progressive operation of the Public Health Act of 1873. A second factor has been the changed attitude towards physical exercise, particularly during the younger ages, that prevails throughout the school to-day. Other causes conducing to the general improvement in physique are the better housing, the increased knowledge and use of foods, and a greater realisation of parental responsibility for the child's health. Dr. Mumford urges that 13 years is the best age for a boy to come to the city school, for then the brain is still in the plastic and receptive stage. He should stay a minimum of four years. It appears, however, that more than 31 per cent. of the boys stay only two years or less.

Post-Graduate Lectures in Manchester.

A series of post-graduate lectures and demonstrations will be given at the Ancoats Hospital, Manchester, throughout the coming year on Thursdays, at 4.15, commencing on Oct. 12th. All members of the medical profession are cordially invited to attend.

Ancoats Healthy Homes Society.

The report of the Ancoats Healthy Homes Society for 1910–11 states that during the 22 years in which the society has been in existence "a vast improvement has taken place in the condition of the district. Whole insanitary areas have been cleared away by the health authorities, the death-rate has been considerably reduced, and Ancoats generally has been made a more tolerable place for those who live there." During the coming winter the society will arrange for lectures on health topics on such subjects as whooping-cough, enteric fever, measles, and consumption. The chief object is to reach the mothers in the district. Each neighbourhood is visited in turn, and fathers and mothers are invited to attend at the hall "just as they are" and bring their children. The lecture is followed by a concert.

Sunstroke as an Employment Accident.

A case of considerable importance has just been decided by the arbitrator at the Preston county court—a claim on behalf of Margaret Wignall for £171 compensation for the death of her husband, a carter in the employ of a firm of hay and straw dealers. Wignall died from meningitis the result of sunstroke. The applicant contended that the sunstroke occurred during the time the deceased was carrying trusses of hay from a stack to a lorry. Wignall carried 72 trusses of hay, each weighing five stones, in one hour and twenty minutes. The arbitrator, Mr. Mansfield, considered that in Wignall's work there was something substantially beyond the ordinary normal risk, that the injury he suffered was largely the result of his work, and that it was thus an accident arising out of the man's employment. An order was made for the sum claimed.

Oct. 3rd.

GUILD OF ST. LUKE.—The eighth annual festival service of the Birmingham Ward will be held in Gloucester Cathedral at 4 P.M. on Thursday, Oct. 26th, when the sermon will be preached by the Bishop of Gloucester. All practitioners are invited to attend, and further particulars respecting the Guild can be had on application to Dr. W. T. Elliott, 65, Temple-row, Birmingham.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

New Medical Chairs in Connexion with the University of Glasgow.

IT will be recollected that in connexion with the clinical teaching at the University of Glasgow a scheme was put forward to reorganise the whole arrangement of affairs, and to try to make use of the abundant clinical material at the Royal Infirmary. The fact that the Western Infirmary is within a stone's throw of the University buildings naturally made it more convenient for medical students to take out their clinical work there. The tendency for students to remain there for all their clinical teaching was perhaps naturally increased by the knowledge that many of their teachers there, owing to the fact that they held university chairs, were, in some instances at least, their examiners at the final examination. Owing to the overcrowding at the Western Infirmary cliniques it was decided to bring out a scheme which would help to divert part of the stream of students to the Royal Infirmary, which, although at some distance from the University, is being rebuilt with all the facilities necessary for the training of students. Hitherto all students at the Royal Infirmary have been practically drawn from St. Mungo's College, an institution in close proximity to the infirmary, governed by its own board of directors, and laying itself out more especially for the training of dental students and those who were aiming at the triple qualification granted by the faculties at Glasgow and Edinburgh. The only feasible scheme to make the Royal Infirmary a clinical training ground which would attract students going up for a university degree was to put it as much as possible on the same footing as the Western Infirmary by founding chairs of medicine, surgery, pathology, and midwifery, the occupants of which would have wards at the Royal Infirmary, would conduct all their teaching there, and at the same time would have seats in the Senate and be examiners at the University. To find money for the founding of these chairs approaches were made to the governors of St. Mungo's College and also to the trustees under the Muirhead trust, who administer money left by the late Dr. Muirhead for the furthering of medical education in Glasgow. After some difficulty an arrangement was come to, and a provisional order was carried through Parliament to allow of the necessary alterations being made. The last step in the process was carried out last week, when the curators appointed various medical men to the new chairs. To the St. Mungo chair of Surgery Dr. Robert Kennedy was appointed, Dr. J. Munro Kerr to the chair of Obstetrics and Gynæcology, Dr. Walter K. Hunter to the Muirhead chair of Medicine, and Dr. John H. Teacher to the St. Mungo (Notman) chair of Pathology. These arrangements have all been made before the opening of the winter session, and it remains to be seen whether the scheme will have the desired effect of distributing the medical students more or less equally between the two institutions. If the Senate decrees that all clinical classes are to be absolutely limited to a certain number, and fixes the number at such a figure that a proportion of the students will find it impossible to get their training at the Western Infirmary, then the scheme will accomplish what it was intended to do. If, on the other hand, no such rule is made by the Senate and it is left to the free will of each individual student which hospital he will attend, it is probable that, partly from the nearness of the Western Infirmary to the University and partly also from tradition, the bulk of the students will still remain at the Western Infirmary.

Legacy for Scottish Hospitals.

Considerable satisfaction has been aroused in those more intimately associated with hospitals in Scotland over the will of Mr. Edward Davis, a native of Glasgow, who died last month at Cheltenham. The residue of the estate, which is a large one, has been bequeathed to charitable institutions in Scotland. It is expected that a sum of £75,000 may be at the disposal of the trustees, and hospitals should benefit largely.

Scarlet Fever in the Mearns.

There has been an outbreak of scarlet fever in Gourdon, with one death, in consequence of which the public school has been closed. At Bervie, also, the two schools have been closed for the same reason by order of the medical officer.

Banff and Medical Inspection of School Children.

A meeting of the Banff school board was held on Sept. 22nd, when the adjourned consideration of the county scheme for medical inspection of the schools was taken up. The position of the matter, as explained by the chairman, was that at the last meeting the adoption of the scheme sent down by the county committee on secondary education was moved and seconded, and a direct negative was moved by Dr. Murray. Fifteen out of 25 schools had agreed to the scheme, and no school had objected. Referring to the criticism by the board of the action of the secondary committee in getting the approval of the department to this scheme before sending it down to school boards, the chairman, on behalf of the committee, explained that this was the only scheme the department was likely to approve of, it being the scheme the department recommended, and it was a mere formality sending it for approval to the department. After some discussion, Dr. Murray said it was the school boards who were required by the department to provide for the medical examination of the pupils attending their schools, to such an extent and subject to the requirements as may from time to time be prescribed. The school board may employ a medical officer and a nurse. It was not the secondary education committee who had the appointment at all. It was the school board. Regarding the cost of the scheme, Dr. Murray said it was stated as £600 for the first year; but it would be very much more. Dr. Murray said they could carry on a scheme of their own at an equally low cost and it would be better done. He wished to say this final word, that if the board departed from what they had previously done they were flinging an insult on the medical profession in this district. Eventually the scheme was carried, the chairman expressing the opinion that any board could withdraw on a year's notice.

Oct. 3rd.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Sixtieth Report of the Inspectors of Lunatics (Ireland).[1]

THE total number of the insane in establishments and in unlicensed houses upon Jan. 1st, 1910, was 24,144. On Jan. 1st, 1911, the total number was 24,394. These figures do not include the insane wandering at large or those residing in private dwellings who are not certified. The figures show that there was an increase of 250 during the year—the increase for the previous year having been 213. The increase was, however, 78 less than the average increase for the preceding ten years, which was 328. The ratio of the increase in the number of the registered insane from year to year, in proportion to the population, is somewhat greater owing to the fact that the general population has been decreasing. From Dec. 31st, 1880, to Dec. 31st, 1910, there was an increase of 11,412 in the total number of lunatics. The inmates of district and auxiliary asylums increased by 11,936; the inmates of private asylums and institutions increased by 287; while the criminal lunatics in Dundrum Asylum decreased by 9, and the lunatics in workhouses decreased by 942. The decrease in the numbers in workhouses is continuing satisfactorily. The admissions numbered 3576, and of these, 2844 were admitted for the first time, while 732 had previously been under care. The total number of patients discharged was 1759, and of these 1307 were recovered, being a percentage of recoveries on the admissions of 36·5, and on the daily average number resident of 6·4. The number of deaths during the year was 1479. The death rate per cent. of the daily average number resident was 7·2. The rate varies from 10·2 in one asylum to 4·4 in another. In 197 cases only were necropsies performed. The number of examinations made, small as it is, tends still further to decrease, the numbers for 1910 being 25 less than for 1909, while the numbers for 1909 were less than those for 1908. The Commissioners again draw attention to the overcrowding which they find in so many asylums and to the consequent necessity for further accommodation. Year after year the same reports and recommendations are made, but apparently they fail to make much impression upon the local authorities.

[1] The Sixtieth Report of the Inspectors of Lunatics (Ireland) for the year ending Dec. 31st, 1910. London: Published by H.M. Stationery Office. Pp. 168 + xxxviii. Price 10½*d*.

Financial Position of the National University of Ireland.

The Dublin Commissioners under the Irish Universities Act, 1908, in a recent report have made clear the necessity for further endowment if the National University is not to meet with disaster. The income of the part of the property of the late Royal University which was conveyed to the National University is not sufficient at present to meet the charges on it, so that the University has as its annual income only the £10,000 a year awarded under the Act and the fees received from its students and graduates. The expenditure of the University in 1910 was, however, £15,534, a sum which exceeded by £1640 its total income for the year. With regard to the finances of University College, Galway, one of the constituent colleges of the National University, the Commissioners make some strong remarks:—

> We felt it our duty to state in our former report that the scheme proposed in the statute for that college did not in any degree conform to our conception of even a passable equipment for a constituent college of the University; that it represented in our opinion merely a makeshift, which we had found to be at the moment practicable, but which was regarded by us not only as unsound, but as constituting an anomaly in the framework of the University system, and from an educational point of view in many respects inadequate. We regret to say that these observations continue to apply to the College. There has not been any increase in its income, and we continue to regard with much apprehension its dangerous pecuniary condition.

Jubilee of the Mater Misericordiæ Hospital.

The golden jubilee of the Mater Misericordiæ Hospital was recently celebrated. The foundation-stone was laid in 1852, and the building was opened, with 40 beds, in 1861. A wing was added in 1872 and another in 1886, so that at present there is accommodation for nearly 350 patients. It was founded and is still maintained by the Sisters of Mercy. One of the original staff of the hospital, Sir Francis Cruise, is still attached to the hospital as consulting physician, and to his constant attention and high reputation much of the success of the institution is due. An interesting point regarding the members of the present staff is that, with the single exception of Sir Francis Cruise, they have all been students of the hospital, which has also supplied teachers to more than one of the other Dublin hospitals. The jubilee was celebrated by the saying of solemn High Mass in the chapel of the hospital, followed by the Benediction of the Blessed Sacrament and the *Te Deum*. A large company was entertained at luncheon, and the Bishop of Canea, who presided, conveyed the Apostolic Benediction from the Pope to the institution, its staff and benefactors. The hospital, though the youngest, is one of the largest in Dublin.

Hospital Supplies and the Strike.

Several of the Dublin hospitals have suffered from their inability to receive supplies during the railway strike. Eggs for the Royal Hospital for Incurables were held up at one station for several days, but were eventually rescued by amateur efforts. Dressings for Sir Patrick Dun's Hospital were similarly held up until a party of the students rescued them. Last week the bakers in the employ of several of the most important bread firms in Dublin went out on strike, while the unaffected firms found themselves unable to supply any but their regular customers. As a result many private houses and public institutions found themselves without enough bread, and several hospitals suffered severely. The Master of the Rotunda, for example, announced publicly that the hospital was entirely deprived of its bread-supply. The matron of Sir Patrick Dun's made a similar announcement, while the Mater Misericordiæ, Mercer's, and Dr. Steevens' hospitals were all in the same painful plight. It was generally held that the action of the strikers was unjustifiable. Within a few hours of the public appreciation of the position of the Rotunda offers of help and parcels of bread began to arrive. From Dublin itself, from the country towns round, from Belfast, and even from London, consignments of bread arrived, while a working baker offered his services to the institutions gratis during the continuance of the strike. Arrangements have now been made to safeguard the supply of the hospitals, which have in the meantime received a remarkable proof of the public feeling of gratitude towards them.

County Down Medical Officers and the Insurance Bill.

A meeting of the North County Down dispensary medical officers was recently held to consider their position under the

National Insurance Bill. The following resolutions were passed unanimously:—

1. That we object to any conditions as to service or remuneration being forced upon us by virtue of our office as dispensary doctors which should not be acceptable to medical men outside our service.
2. That we pledge ourselves to resist any such tyrannous and unjust attempts, by every legitimate means in our power, to try to compel us to accept such terms, and to deprive us of the same freedom of contract as other members of our profession.
3. That we approve of Poor-law legislation being undertaken on the basis of the able and exhaustive report issued by the Poor-law Vice-regal Commission as likely to be more effective and more just than any other scheme before the country, and more suited to its needs and the genius and circumstances of the Irish people.

The Water Famine in the North of Ireland.

At a meeting of the waterworks committee of the urban council of Monaghan, held on Sept. 27th, it was decided to cut off the supply of water to the public institutions—which includes the Monaghan and Cavan Asylum, where there are over 900 patients—and to supply the water to the ratepayers alone for a limited period. The Monaghan water-supply has almost completely failed, the reservoir being nearly empty, and the only water available is some which is being pumped at much expense from Greagh Lake. In Londonderry it is believed that at the present rate of consumption the quantity of water in the reservoirs cannot possibly hold out more than a month. It has been decided to take steps to procure an additional supply. In the meantime, the supply of water was cut off from last Saturday to Monday, and the chairman of the water commissioners stated at the last meeting that the next expedient would be to shut off the supply on four or five days each week.

River Pollution.

One of the linen industries at Portadown has demanded from the Portadown town council the right to the free flow of water of a river into which town sewage passes, an abatement of the nuisance in the river, a supply of water from the Portadown town supply, a clearing out of the sewage from the river opposite their premises, and a payment of £120 to cover their liquidated damages and costs up to the present. If this is not done, an injunction is threatened. The chairman of the town council of Portadown says that to comply with the requirements would mean that the council would have to undertake a main drainage scheme costing £40,000 to £50,000. Certainly these demands raise the question, Should a free supply of town water be given to every factory-owner who complains? The whole problem, a very serious one, is to be considered by the Portadown council in committee. It has already obtained a good water-supply, and will in the end be wiser, despite the great cost, to obtain a main drainage scheme.

Salaries for Urban Councillors.

At the Dungannon urban council, on Oct. 2nd, the following resolution, extraordinary in every way, was unanimously adopted:—

That we call upon the Government to pass an Act of Parliament to demand State payment for all municipalities in Ireland, and to place us on the same terms as the Members of Parliament in England, as I (i.e., proposer of the motion) consider that we, the county councillors, rural district councillors, and urban councillors, are a greater service to the State than most of the Members that are getting £400 a year.

Oct. 3rd.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The Consumption of Alcohol in France.

FOR many years the consumption of alcohol increased to an alarming degree in France. Physicians and hygienists especially were disquieted, for the results speedily became visible as much in a predisposition to contract different diseases in an aggravated form, as in the fatal influence that alcohol gradually exercises on the mind and in the indolence that its abuse induces. Dr. Jacques Bertillon, however, has now made reassuring utterances in a communication on the Diminution in the Consumption of Alcohol in the Larger French Cities to the Academy of Moral and Political Sciences on Sept. 30th. He exhibited to the Academy 33 diagrams relating to as many cities, from which it appears that the consumption of brandy has considerably diminished since the application of the law reducing the tax on wine and beer and increasing that on distilled beverages. The history of alcohol in France shows that a moderate increase of a tax has no sensible influence on the consumption. As a consequence, however, of the enormous imposts placed on distilled drinks, the consumption of alcohol has greatly diminished in the towns, but not in the country. This is due to the fact that the increase of the town toll is there added to that of the tax; while the duty on wine being lowered, the retailers are interested in selling wine rather than brandy. Formerly the consumption of brandy was almost the same in all the groups of cities—namely, from 7 to 8 litres of absolute alcohol per head—while in the country districts it was only 2·84 litres. It has now fallen to 6 litres in the small towns of from 4000 to 10,000 inhabitants, and to a still smaller figure in the more important towns; while in towns of more than 90,000 inhabitants it has fallen to 4·23 litres. The fall has been most marked in the large towns; in the country districts it has been negligible or absent.

The Effect of the Drought on the Eyes.

Among the numerous inconveniences entailed by the great heat of the past summer has been the great dryness that has prevailed everywhere. In the large towns, particularly where the principal streets, avenues, and boulevards are paved with wood, a serious and unexpected consequence has appeared. The transit of numerous vehicles over this wood pavement, inoffensive though it may be in normal times, ceases to be so in periods of prolonged dryness. The constant friction of the wheels on the wood paving disperses through the air minute particles which get into the eyes. These particles are the more painful in that, being pointed, microscopical though they are, they cause minute abrasions. Numerous cases of eye-trouble have been thus produced. This great heat is naturally accompanied by a more glaring light, due to the excessive brilliancy of the sun, which reflects most painfully on the eyes. On all hands, therefore, oculists have been recommending for eye-glasses the use of yellow glasses which allow some light to pass through; they give a considerable sensation of comfort and allow of a clear appreciation of distances and increase the relief in which objects stand out.

Oct. 2nd.

UNITED STATES OF AMERICA.

(FROM OUR OWN CORRESPONDENT.)

The Thirteenth Annual Conference of the American Hospital Association.

THE Thirteenth Annual Conference of the American Hospital Association, held in New York from Sept. 19th to 22nd under the presidency of Dr. W. L. Babcock of Detroit, was highly successful. The audience was largely composed of women, mostly superintendents or matrons of hospitals, or nurses. They took their part in the papers and discussions with great ability. As speakers they compared favourably with the men. The programme was long, so it must suffice to refer to only some papers of outstanding public concern. Mr. George McAneny, president of the Borough of Manhattan, in welcoming the members to New York, took as his subject hospital reform. He sharply criticised New York's divided system of hospital supervision and advocated a centralisation of the hospitals of the city. He deprecated the action of the city authorities in amending the provision included in the new charter for centralising the control of some of the city hospitals, asserting that it had put the situation back into its former position.

The first, and perhaps the most generally interesting, paper read was by Dr. J. N. E. Brown, of Toronto, until recently superintendent of the Toronto General Hospital. Dr. Brown had just returned from a tour of inspection of hospitals in Great Britain, Germany, France, Austria, and Holland. He referred to the various systems of hospital support, and considered that State or municipal support of such institutions, as in vogue on the continent, was superior to the voluntary method of Great Britain and the partially voluntary method of America. Dr. Brown also appeared to be favourably prepossessed with the European method of hospital administration, and stated that in his opinion "a medical man, *cæteris paribus*, makes the best sort of director of a large hospital, but when appointed to fill such a position he should be relieved of work which belongs to the medical staff. The proper administration of a large hospital demands the sole attention

of the head." He briefly described the organisation of European hospitals, and expressed himself in favour of the European system generally. As to hospital construction, Dr. Brown thought that the architects of the best of these institutions in Europe had little to learn from their American and British *confrères*. He was especially impressed with the situation of many of the large continental hospitals, placed in large and beautiful grounds, affording plenty of fresh air and secluded from noise. Another feature of some of the Dutch and German hospitals which greatly struck Dr. Brown was the ample provision of bath-houses and of disinfection-houses. Finally, the much-vexed question of ventilation was dealt with, and many of the methods, elaborate and otherwise, for securing a constant supply of fresh air in the wards of hospitals were described at length.

Mr. Edward F. Stevens, A.A.I.A., of Boston, Mass., Dr. Brown's companion during his European pilgrimage, dealt at considerable length with the details and equipment of British and continental hospitals, and compared these with the details and equipment of American hospitals. Mr. Stevens showed on a screen illustrations, exterior and interior, of numerous hospitals visited.

Another excellent paper was read by Mr. J. M. Cosgrave, manager of the Winnipeg General Hospital, on the Development of Typhoid Fever among Hospital Workers. It really was a vindication, if such were needed, of preventive anti-typhoid vaccination. Mr. Cosgrave said that until anti-typhoid vaccine came into use it had been almost impossible to prevent the spread of the disease among nurses and hospital employees; but since its use became general typhoid fever among hospital employees had almost ceased. Dr. H. W. Austin, of the United States Public Health and Marine Hospital Service, also eulogised the efficacy of the vaccine, and said it was being used more and more in the navy hospitals, and with success. Dr. Morrell of Baltimore told of the results of its use in the United States army camp at San Antonio during the manœuvres, and said that among 1200 men who submitted to the treatment only one contracted the disease, and that in a mild form. Dr. Willie G. Neally, assistant superintendent of the New York Hospital, emphasised the importance of properly administering anæsthetics, which was frequently as essential to operative success as the work of the surgeon.

Mr. Robert W. Hibberd, secretary of the State Board of Charities of New York, complained that the hospital facilities of New York city were woefully inadequate to the needs of the population. He further stated that the system of management was far too complicated, and he also was of opinion that centralisation of the hospital organisation was required. The plans of the State Board of Charities, the great hospital department of the city, which cares, probably, for three times more patients daily than the other hospital departments, he said, contemplate that Blackwell's Island shall eventually become a great hospital park for the care of the adult sick poor, that Randall's Island shall be made into a park for sick children, that the King's County Hospital property shall be dealt with in a similar manner, and that the relatively able-bodied poor, who are really the ones cared for by the department, shall be maintained at the Farm Colony on Staten Island, where they may be given plenty of work suited to their strength and capacity. Mr. Hibberd concluded that New York was a generation behind the age in its public hospital and ambulance facilities. To bring it up to date it urgently required a unified hospital and ambulance system.

Mr. Abraham Flexner, of the Carnegie Foundation, one of the authors of the report on the medical schools of America, read a paper on hospital organisation and research, wherein he reiterated the charges made in his report against small and inefficient medical schools. Mr. Flexner pointed to the satisfactory fact that 20 medical schools of this class had gone out of existence during the past year, owing to the campaign among the hospitals which permitted them to flourish. Mr. Flexner concluded by naming several medical schools which, he said, ought to be closed. Mrs. Margaret Engelhart, president of the Association of the Frances Willard Hospital of Chicago, took exception to Mr. Flexner's strictures on certain of these medical schools, and stated from personal knowledge that at least one of them produced as fine a student body as could be desired, and that a graduate of that school would be welcome on the staff of the Frances Willard Hospital. The Rev. A. S. Kavanagh, superintendent of the Methodist Episcopal Hospital, Brooklyn, read the report of the committee on hospital efficiency, hospital finance, and economics of administration, and incidentally paid a well-merited tribute to the work done by Dr. Doty as health officer of the port of New York. This expression of the gratitude of the citizens of New York to Dr. Doty was peculiarly fitting, in that recently Dr. Doty has been fiercely assailed with charges of neglect of duty by political opponents.

Sept. 25th.

Medical News.

EXAMINING BOARD IN ENGLAND BY THE ROYAL COLLEGES OF PHYSICIANS OF LONDON AND SURGEONS OF ENGLAND.—At the First Professional Examination of the Conjoint Examining Board held on Sept. 26th, 27th, 28th, and 29th, the following candidates were approved in the under-mentioned subjects:—

Chemistry and Physics.—William Fletcher Barrett, Birkbeck College; Christopher Frank Good, London Hospital; Frederick John Good, London Hospital; Elma Jamilla Ishmael, London School of Medicine for Women; Reginald Jenner-Clarke, London Hospital; Paul Rustat Ellis Kirby, Brighton Technical College; Louisa Margaret Lister, Bristol University; John Frederick Munton Payne, London Hospital; Thomas Melville Payne, University College, Cardiff; Nirendra Mohan Sen-Gupta, London Hospital; Violet Annie Shaw, Birkbeck College; and Cecil Pembrey Grey Wakeley, Dulwich College.

Chemistry.—Hugh Stanford Bryan, London Hospital; Joseph Adrian Hart, London Hospital; Reginald Fitzroy Jarrett, London Hospital; Thomas William Le Mesurier, London Hospital; William Dundas McRae, London Hospital; Dudley George Pearce, Guy's Hospital; Walter Davies Pearman, Birmingham University; and Ernest Wayte Terry, Manchester University.

Physics.—Henry Searle Baker, St. Bartholomew's Hospital; Gauri Dayal, Bombay and Manchester Universities; Eldon Munro Litchfield, Otago University; George Samuel Bousfield Long, Guy's Hospital; Gerald Richardson Sharp, London Hospital; and William Walford Salisbury Sharpe, St. Mary's Hospital.

Biology.—Richard Ambler, Middlesex Hospital; Henry Searle Baker, St. Bartholomew's Hospital; William Fletcher Barrett, Birkbeck College; Christopher Frank Good, London Hospital; Ernest Gwyn Howell, University College, Cardiff; Reginald Jenner-Clarke, London Hospital; Theodore Louis Kan, King's College; Percy Gunn Russell, Middlesex Hospital; and Violet Annie Shaw, Birkbeck College.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—At the Preliminary Science Examination for the Licence in Dental Surgery, held on the same dates, the following candidates were approved in the subjects specified:—

Chemistry and Physics.—Ernest Bailey, Harris Institute, Preston; William Milton Bull, West Ham Technical School; Arnold Court, Banbury Municipal School and Birmingham University; Frederick Andrew Craine, Middlesex Hospital; Herbert Ronald Cullwick, Wolverhampton Grammar School; Launcelot Machin, Guy's Hospital; and David Stewart, Salford Royal Technical Institute.

Physics.—Ellis Larner Cooke, Battersea Polytechnic; John Langley Garrard, Guy's Hospital; William Henry Churchill Gordon, Guy's Hospital; Sidney Francis Greenfield, Northern Polytechnic Institute; and Edgar William Smith, Charing Cross Hospital.

Chemistry.—Walter Lawton Cocker, Halifax Municipal College; Tom Geoffrey Melsome Parker, Middlesex Hospital; and William John Ross, Salford Royal Technical Institute.

GUY'S HOSPITAL MEDICAL SCHOOL.—The following entrance scholarships and certificates have been awarded:—Junior science scholarships: £120, Leonard Snowden Debenham, St. Paul's School, West Kensington; £60, Peter George McEvedy, preliminary science class, Guy's Hospital; certificate: James Gayner Jones, preliminary science class, Guy's Hospital. Entrance scholarship in arts: £100, Thomas Albert Victor Wood, Wolverhampton Grammar School; £50, F. Gilbert Scott, B.A., Merton College, Oxford; certificate: Douglas A. Dyer, Berkhamsted School. In the Dental School the following entrance scholarships were awarded:—Dental mechanics: open scholarship, G. L. Cutts; pupils' scholarship, A. F. Rook.

NATIONAL UNION OF PUBLIC HEALTH AUTHORITIES.—A conference of Public Health authorities, under the auspices of the above union, will be held in the Council Chamber, Caxton Hall, Westminster, at 10 A.M., on Friday, Oct. 13th, to consider: (1) the urgent need for dealing immediately, on national lines, with the question of the prevention and treatment of tuberculosis; and (2) the provisions of the National Insurance Bill, in so far as they affect Public Health authorities, especially those relating to the proposed Local Health Committees. In order to influence

legislative action on both these questions the executive committee feels that it is of vital importance that any resolutions or recommendations submitted to the Government should reflect the united opinion of Public Health authorities throughout the country. The conference will therefore be open to the representatives of all Public Health authorities, whether members of this union or not.

Dr. Watson Williams will deliver the inaugural lecture on the Influence of the Upper Air Tract on Respiration, illustrated by lantern slides, at the Central London Throat and Ear Hospital, on Friday, Oct. 27th, at 3 P.M.

A MEMOIR of Sir John Burdon Sanderson is on the eve of publication by the Oxford University Press. Lady Burdon Sanderson had completed four chapters when she died, and the work has been finished by Mr. J. E. Haldane and Miss E. S. Haldane, who have added some of their uncle's papers and addresses on subjects of general interest.

THE SALE OF CORROSIVE ACIDS.—The Privy Council regulations for the sale of corrosive mineral acids came into force on the first day of this month and should do much to lessen the number of fatal accidents from these poisons among the poorer classes. The need for such regulations has long been felt, and has often been expressed in coroners' courts by medical witnesses and coroners, notably by Dr. F. J. Waldo, who referred again to the matter at an inquest on a case of hydrochloric acid poisoning on Sept. 27th in the City Coroner's Court. The new regulations lay down that sulphuric, hydrochloric and nitric acids, and "salts of lemon" must only be sold by retail in bottles, distinguishable by touch from ordinary bottles and bearing on a label the name and address of the vendor, together with the words "Poisonous" and "Not to be taken." In future the sale of the above acids in violation of these regulations will be subject to a fine of £5. On Feb. 1st, 1912, ammonia will also be included in the list.

DONATIONS AND BEQUESTS.—By his will the late Mr. Henry Overton Wills, first Chancellor of the University of Bristol, made the following bequests to medical charities and organisations, as well as a number of others of a public character:—Bristol General Hospital, £3000; Royal Hospital for Incurables, Putney, £3000; British Home and Hospital for Incurables, Streatham, £2000; Bristol Royal Hospital for Sick Children and Women, £2000; Her Majesty's the late Queen's Nurses, £2000; National Hospital for Paralysed and Epileptic £500; Bristol District Nurses' Society, £500; Weston-super-Mare Children's Convalescent Home, £250; Royal United Hospital, Bath, £500; Western Dispensary, Bath, £200; and Combe Down Convalescent Home, £200. The will also confirms the gift of £100,000 to the University of Bristol. The estate is provisionally sworn at £2,000,000.—An offer of £12,500 has been made towards the scheme for the extension of Chester Infirmary by Mr. Albert Wood of Bodlondeb, Conway.—Miss Best of London has also given £1000 for the endowment of a bed in memory of her sister, formerly a resident at Chester.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.*

BURFIELD, J., M.B., B.S. Lond., F.R.C.S. Eng., has been appointed Honorary Assistant Surgeon to the Norfolk and Norwich Hospital.

HUNTER, WALTER K., M.D. Glasg., has been appointed to the Muirhead Chair of Medicine in the University of Glasgow.

MIDDLEWEEK, FREDERICK FRANCIS, L.R.C.P. & S. Edin., L.F.P.S. Glasg., has been appointed Honorary Director of Mechano-Therapeutics and Massage at the West-End Hospital for Nervous Diseases.

MILLIGAN, E. H. M., M.D.Q.U.I., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Long Eaton District of the county of Derby.

TEACHER, JOHN H., M.D. Glasg., has been appointed to the Mungo Chair of Pathology in the University of Glasgow.

WALKER, C. F., M.D. Lond. (State Med.), B.S. Lond., D.P.H. Vict., has been appointed Resident Medical Officer of the Leicester Isolation Hospital.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

BATH, EASTERN DISPENSARY.—Resident Medical Practitioner. Salary £130 per annum, with apartments, coals, gas, &c.

BIRKENHEAD EDUCATION COMMITTEE.—Assistant School Medical Officer. Salary £260 per annum.

BIRMINGHAM CITY FEVER HOSPITAL, Little Bromwich.—Medical Superintendent. Salary £250 per annum, with board and residence.

BIRMINGHAM, QUEEN'S HOSPITAL.—Obstetric and Ophthalmic House Surgeon. Salary at rate of £50 per annum, with board, lodging, and washing.

BODMIN, CORNWALL COUNTY ASYLUM.—Third Assistant Medical Officer, unmarried. Salary £140 per annum, with rooms, rations, laundry, and attendance.

BOLINGBROKE HOSPITAL, Wandsworth Common, S.W.—Two House Surgeons for six months. Salary at rate of £75 per annum, with board and residence.

BRIGHTON, HOVE, AND PRESTON DISPENSARY.—Resident Medical Officer, unmarried. Salary £160 per annum, with rooms, &c.

BURSLEM, HAYWOOD HOSPITAL.—Resident Medical Officer (female). Salary £100 per annum, with board, residence, and laundry.

BURY INFIRMARY.—Junior House Surgeon. Salary £80 per annum, with board, residence, and laundry.

CAMBRIDGE, ADDENBROOKE'S HOSPITAL.—Second House Surgeon. Salary £80 per annum, with board, residence, and laundry.

CHESTER, CITY OF.—Assistant Medical Officer of Health. Salary £250 per annum.

CHESTERFIELD AND NORTH DERBYSHIRE HOSPITAL.—House Physician. Salary £80 per annum, with board, apartments, and laundry.

CITY OF LONDON LYING-IN HOSPITAL, City-road, E.C.—Assistant Physician.

COLCHESTER, ESSEX COUNTY HOSPITAL.—House Surgeon. Salary £80 per annum, with board, washing, and residence.

COVENTRY AND WARWICKSHIRE HOSPITAL.—Two Junior House Surgeons. Salary £80 per annum, with rooms, board, washing, and attendance.

DEVONPORT, ROYAL ALBERT HOSPITAL.—Assistant House Surgeon, unmarried, for six months. Salary at rate of £75 per annum, with board, apartments, laundry, &c.

DUDLEY, GUEST HOSPITAL.—Assistant House Surgeon for six months. Salary £75 per annum, with residence, board, and washing.

EAST SUFFOLK COUNTY EDUCATION COMMITTEE.—Assistant School Medical Officer. Salary £250 per annum.

EXETER, ROYAL DEVON AND EXETER HOSPITAL.—House Physician and Assistant House Surgeon for six months. Salary at rate of £60 per annum, with board, apartments, and washing.

GLASGOW DISTRICT MENTAL HOSPITAL, Lenzie.—Junior Assistant Medical Officer. Salary £125 per annum, with board, lodging, and washing.

HAMPSTEAD GENERAL AND NORTH-WEST LONDON HOSPITAL.—Surgeon to Out-patients.

HASTINGS, EAST SUSSEX HOSPITAL.—Assistant House Surgeon. Salary at rate of £60 per annum, with residence, board, and washing.

HOMERTON INFIRMARY.—Medical Superintendent and Medical Officer of the Homerton Children's Homes, &c. Salary £500 per annum, with luncheon, tea, &c.

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Brompton.—House Physician for six months. Salary 30 guineas.

HOSPITAL FOR EPILEPSY AND PARALYSIS AND OTHER DISEASES OF THE NERVOUS SYSTEM, Maida Vale, W.—Resident Medical Officer for six months. Salary at rate of £50 per annum, with board, lodging, and washing.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street, London, W.C.—Assistant Casualty Medical Officer, unmarried, for six months. Salary £30, with board, residence, &c.

HULL ROYAL INFIRMARY.—Two Casualty House Surgeons. Salary at rate of £80 per annum, with board and lodging.

INVERNESS DISTRICT ASYLUM.—Junior Assistant Physician. Salary £140 per annum, with board, lodging, and laundry.

LEEDS GENERAL INFIRMARY.—Resident Medical Officer. Salary £150 per annum, with board, residence, and washing. Also Resident Obstetric Officer and Two House Physicians for six months, each with board, lodging, and washing. Also Three House Surgeons for twelve months. Also Resident Medical Officer for the Ida and Robert Arthington Hospitals for six months. Salary £30, with board, lodging, and washing.

LEEK, CHEDDLETON ASYLUM.—Locum Tenens Assistant Medical Officer for four months. Salary 4 guineas per week, with board, residence, and washing.

LEICESTER BOROUGH EDUCATION COMMITTEE.—Assistant Medical Officer. Salary £250 per annum.

LEICESTER INFIRMARY.—Assistant House Surgeon for six months. Salary at rate of £80 per annum, with board, apartments, and washing.

LIVERPOOL STANLEY HOSPITAL.—Two Junior House Surgeons. Salary £70 and £60 per annum respectively.

LOWESTOFT HOSPITAL.—House Surgeon, unmarried. Salary at rate of £100 per annum, with board, residence, and laundry.

MELROSE, ROXBURGH DISTRICT ASYLUM.—Assistant Medical Officer. Salary £160 per annum, with board, lodging, and washing.

METROPOLITAN HOSPITAL, Kingsland road, N.E.—House Physician, House Surgeon, Assistant House Physician, and Assistant House Surgeon for six months. Salary of House Physician and House Surgeon at rate of £60 per annum, with board and washing. Salary of Assistant House Physician and Assistant House Surgeon at rate of £40 per annum, with board and washing.

NEWPORT AND MONMOUTHSHIRE HOSPITAL.—House Surgeon. Salary £60 per annum, with board, residence, and laundry.

NOTTINGHAM GENERAL HOSPITAL.—Assistant House Physician. Salary £100 per annum, with board, lodging, and washing.

NOTTINGHAM WORKHOUSE INFIRMARY.—Resident Assistant Medical Officer, unmarried. Salary £150 per annum, with apartments, board, washing, and attendance.
OLDHAM ROYAL INFIRMARY.—Third House Surgeon for six months. Salary £80 per annum, with board, residence, and laundry.
OLDHAM UNION WORKHOUSE.—Resident Assistant Medical Officer.
PLYMOUTH, SOUTH DEVON AND EAST CORNWALL HOSPITAL.—Assistant Surgeon.
PRINCE OF WALES'S GENERAL HOSPITAL, Tottenham, N.—Senior House Physician. Salary £75 per annum. Also Senior House Surgeon. Salary £75 per annum. Also Junior House Physician. Salary £50 per annum. Also Junior House Surgeon for six months. Salary £50 per annum, with residence, board, and laundry.
READING, ROYAL BERKSHIRE HOSPITAL.—House Physician and Second House Surgeon for six months. Salary £80 and £60 per annum respectively, with board, lodging, and washing.
REDHILL, EARLSWOOD ASYLUM.—Junior Assistant Medical Officer, unmarried. Salary £150 per annum, with board, residence, and washing.
ROYAL ARMY MEDICAL CORPS.—Twenty Commissions.
ROYAL DENTAL HOSPITAL, Leicester-square, W.C.—Clinical Pathologist and Demonstrator on Bacteriology. Salary £75 per annum.
ROYAL EAR HOSPITAL, Soho.—House Surgeon. Salary £40 per annum. Also Assistant Surgeon.
ROYAL EYE HOSPITAL, Southwark, S.E.—House Surgeon for six months. Salary 50 guineas per annum, with board and residence.
ROYAL FREE HOSPITAL, Gray's Inn-road, W.C.—House Physician and House Surgeon for six months. Board, lodging, and washing provided. Also House Physician and House Surgeon (females). Board, lodging, and washing provided.
ROYAL HOSPITAL FOR DISEASES OF THE CHEST, City-road, London, E.C.—Resident Medical Officer for six months. Salary at rate of £120 per annum, with board, lodging, and washing.
ROYAL NAVAL MEDICAL SERVICE.—Fifteen Commissions.

ST. MARY'S HOSPITAL FOR WOMEN AND CHILDREN, Plaistow, E.—Senior Resident Medical Officer, unmarried. Salary at rate of £100 per annum, with board, residence, and laundry.
SALFORD ROYAL HOSPITAL.—Casualty House Surgeon for six months. Salary at rate of £50 per annum, with board and residence.
SHEFFIELD ROYAL INFIRMARY.—Three Junior Resident Medical Officers. Salaries £60 to £65 per annum.
STOCKPORT INFIRMARY.—Junior House Surgeon. Salary £80 per annum, with board, washing, and residence.
STRAND UNION SCHOOL, Millfield House, Upper Edmonton.—Medical Officer. Salary £80 per annum.
TAUNTON AND SOMERSET HOSPITAL.—Resident Assistant House Surgeon for six months. Salary at rate of £80 per annum, with board, lodging, and laundry. Also Honorary Physician.
TEIGNMOUTH HOSPITAL, S. Devon.—House Surgeon. Salary £80 per annum, with board, lodging, and laundry.
TOTTENHAM EDUCATION COMMITTEE.—Ophthalmic Surgeon. Salary £25 per annum, plus 2*s.* 6*d.* for each scholar examined and prescribed for.
WADSLEY, NEAR SHEFFIELD, SOUTH YORKSHIRE PAUPER LUNATIC ASYLUM.—Medical Superintendent. Salary £750 per annum.
WALSALL AND DISTRICT HOSPITAL.—House Physician and Casualty Officer. Salary £80 per annum, with board, residence, and laundry.
WESTON-SUPER-MARE HOSPITAL.—House Surgeon, unmarried. Salary £100 per annum, with board and residence.
WHITTINGHAM, NEAR PRESTON, COUNTY ASYLUM.—Pathologist and Assistant Medical Officer. Salary £200 per annum, with board, apartments, and washing.
WOLVERHAMPTON AND STAFFORDSHIRE GENERAL HOSPITAL.—House Surgeon for six months. Salary £80 per annum, with board, rooms, and laundry.

THE Chief Inspector of Factories, Home Office, London, S.W., gives notice of a vacancy as Certifying Surgeon under the Factory and Workshop Act at Christchurch, in the county of Hants.

Births, Marriages, and Deaths.

BIRTHS.

BENETT.—On Sept. 24th, at Jubbulpore, India, the wife of Captain A. M. Benett, R.A.M.C., of a son.
RABAGLIATI.—On Sept. 29th, at Brookton, Western Australia, the wife of A. H. Rabagliati, M.D., F.R.C.S.E., of a daughter.

MARRIAGES.

FOWLER—CANT.—On Sept. 29th, at 8, Midmar Drive, Edinburgh, William Hope Fowler, M.B., Ch.B., F.R.C.S.E., to Julia, youngest daughter of the late James Cant, Ore Bridge, Thornton. At home, 8, Midmar Drive, Nov. 7th, 8th, 9th, and 10th.
LANE—STEPHENS.—On Sept. 26th, at St. John's Church, Roundhay, Gordon J. Lane, M.D., to Margaret Louise, widow of the late W. Ryan Stephens.

DEATHS.

BLANC.—On Sept. 30th, at Paris, Sir Henry Jules Blanc, K.C.V.O., M.D., I.M.S., F.R.C.P. (retired), aged 80 years.
HARDING.—On Sept. 27th, at Osman House, 118, Cromwell-road, Montpelier, Bristol, John Alfred Harding, M.R.C.S., L.R.C.P., L.S.A., aged 84 years.
STOPFORD-TAYLOR.—On Sept. 29th, at Standishgate, Meols Drive, West Kirby, in her 54th year, Ann Alice, the wife of Dr. Stopford-Taylor, of West Kirby and 26, Rodney-street, Liverpool.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

DR. WILLIAM HARVEY IN THE LAZARETTO.

THE latest volume issued by the Historical Manuscripts Commission consists of a further report (the fifth) on the extensive collection of MSS. of the Earl of Denbigh, preserved at Newnham Paddox, Warwickshire. Mrs. S. C. Lomax, who prepared and edited the report, calls attention, in her introduction to the volume, to an interesting group of about a dozen letters written by Dr. William Harvey, the great physician, to Lord Feilding, and relating to a quite unknown incident in the doctor's life. In 1636, as is well known, he accompanied Lord Arundel on his mission to the Imperia Court. Passing through the "ruined, desolate country of Germany," they arrived at Lintz, where the Ambassador had his first audiences, and where Dr. Harvey went twice or thrice a hunting with the Emperor. While waiting for an answer to England's proposals, Lord Arundel and Harvey went to Vienna, where they visited the Queen of Hungary and the Archduke, "and two very fine little babies, her children." Thence Dr. Harvey went to Baden, near Vienna, to see the baths. "After this, we hear nothing more for three weeks, but it is evident that after parting from Lord Arundel at Ratisbon he arranged to visit Lord Feilding at Venice. We may conjecture that he went by Munich, Innsbruck, the Brenner, and the Putzerthal. At any rate, we find that he eventually reached Villach in Carinthia, crossed into Venetian territory at Pontebba, and travelled by Sacile and Conegliano to Treviso. But there, when he was joyfully expecting to be that night with his friend at Venice, he was stopped by the podesta, on the plea that his passport was not properly *visé*, and that he came from places infected with the plague. The podesta even demanded that he should go into the lazaretto. In vain Harvey protested that he was travelling with pass and recommendations from the Emperor and the English Ambassador, that his business required haste, and that if he had come from infected places he would have been stopped at the Venetian frontier; the officer would listen to no reason." The following extracts from Harvey's letters to Lord Feilding show exactly what occurred:—

"1636, Aug. 3-13. Treviso.—My sweete lord, I came this morning to the gates of Treviso with greate joy, and hoped this night to have had the happines to have beene with you att Venise, butt I have receyved heare a very unjust affront, being stayed and commanded by this podesta to have gone into the lazaretto, without any cause or suspition alledged. I took my first *fede* under the seale of Ratisbone, a place free, and now destined, as your Eccellency knoweth, for the meeting of the Emperor and all the rest of the princes, which yf it had not beene soe, they would not have com thither, it being infected or suspected. Since, in every place as I came, I caused my *fede* to be underwritten, soe that there is no ground for them to lay any suspition upon me. And att this sentence on me by the podesta (that I should goe to the Lazarett) I absolutely refused, and sayd and offered to shewe that I had the pass and recommendation of his Majesty the King of Great Brittane and of the Emperors Majesty and of my lord Embassador his Eccellency, and that I had to goe to princes and men of quality, and that my business required expedition, and desier'd they would not hinder me, butt, as my passes required, further me and that I mought not bring that suspition and infamy on me, besides my own security, to go to such a place as lazaretto, whear they use to putt infected persons, and that I had shown them sufficient *fede*. Notwithstanding all this, heare I am to lye for ought I see in the open base [*sic*] feilds, God knows how long. The podesta refuseth to see or reade my passes, and I cannot cum att him to speake and use my reasons. I am afrayd this lying in the feild will doe me hurt in my health. I beseech your Eccellency to lamen hearof. It is unjust to proceed with any man thus without cause and otherwise then Venetians are used in Ingland or so merrit to be used heare, and otherwise then is fitting for the respects there shold be used in the passes forenamed. I pray pardon this scribbling on the grass in the feild, and procure with all expedition my freedom from this barborous usadg. Your distressed frend and humble servant of your Eccellency.

"1636, Aug. 6-16. Saturday.—I perceyve heare by their behavier to me how much your Eccellency is pleased ther to stirr and labor for me, for yesterday after I had sent my letter to your Eccellency, they sent sum in a coatch to me, as from the podesta, that I should goe to the other place, where I was before (yf I would) or that I should have heare a bed, or that he would doe for me what he could, to which I answeared that since it had pleased him with soe much rigour and cruelty to inflict upon me the greatest misery he could and had brought soe much infamye upon me as to putt me into this lazaretto without any just cause, without any respect of the reccommendations I had from my lord Ambassador his Eccellency or from the Emperors Majesty or from his Majesty

my master, not soe much as to reade them or give notice of them in his first dispatch to Venis, nor to make any difference of a servant of his Majestye the King of Greate Brittan, butt by force and threatning of muskets to compell me into the very nasty roome wheare the vitturin and his two servants and saddels lay and not att my request granting me a bed or any commody scarce straw; his offers now weare unseasonable and like phisick when a man was ded and that I had now hardened my self and accomodated as I did content myself and resolved, since it had pleased God by his hands to humble me soe low, I would undergo it as a pennance and that I had writtan to your Eccellency and hoped by your intercession within sum few days to have release, and therefore determined to receyve and acknowledge all my comfort from you and to troble the podesta with noe other request but that he would with all expedition free me and shew a respect to my master and my bysines; and debating the bysines and urging them for a reason of all this and that it was unjust to detayne any man and not show him the cause, or to receyve a man into ther territoryes and then imprison him, they should have denied me entrance att the first and then I had gone sum other way for they should have putt those townes they suspect into ther bands and then I had shunned them or make known att his entrance to every man what he was to doe, otherwise this was to surprize and catch men; and they knowing not well what to answear sumtime alledged that Villach was suspected, sumtime I had not gotten my *fede* subscribed att Conian or Sacile, sumtime that the vitturin had brought a boy with him, his son to gett a master, whose name was not in the vitturins *fede*, soe sumtime I was stayed for him, sum time (they sayd) he and his horses stayed for me. ..... I write the larger to your Eccelency of those passages because I know not what they may make of my conference in ther letters that ye may know the truth, and indeed my lord I am a little jealous of them, and to take anny beds now of their sending, for since ther manners and cruelty hath been soe shamefull to me, and they have soe little reason for what they have done, it would be like the rest of their proceedings yf they sent me an infected bed to make ther conjectures and suspitions prove true; therefor I choose to ley still to be redeemed by your Eccelency oute of this inocent straw. Yesterday likewise the patron that owed the howse wheare I first took my straw bed (a little poore garden howse full of lumber, durt and knatts, without window or dore, open to the highway att midnight) was to offer me that agayne, because I had chosen that to shun the infamy of this lazaret and the suspition I had that sum infected person had lately bene heare, and from which they forced me with terror of muskets, I write this to show your Eccelency that all they doe heare upon your stirring is butt formal to salve their oun errors. I tell them I desier nothing of them, or expect or will except, but only beseech the podesta that I may be att liberty with all expedition, and that att last he will have respect to princes recommendations and to my bysines; and now as I am writing I humbly thank your Eccelency, your servant is arrived and hath bene with me and is gone to the podesta according to your order. He will tell you of a trick to burn my pass and the injury they have offered me therein. ..... Yf they make difficulty of my comming to Venis, I pray that I may have sufficient *fede* from hence and I will goe by Padua to Florence and see your Eccelency as I retorne. I pray pardon me for propounding this to your Eccelency whoe know better hearin what is to be done which I doute not but you will performe, that I may be free and we rejoyse together heareafter; and in good sober truth I feare least this ill usadg and base place and the unquiett of my mind may not bring sum sicknes on me this extream hott wether therefor I beseech, etc. Your Eccelency's humble servant.

"1636, Aug. 9-19, Tuesday afternoon.—My sweete lord, this place is soe incommodious to me, and affordeth me soe little comfort, as I beseech your Eccelency to pardon me yf I take the bowldnes herein to make my complaynts unto you. The great longing I have to be gon and free maketh me thinke these 4 days past (since I had the comfort to see your servant here) to appeare soe maney yeares, whearin I hoped ether they would have relented of ther cruelty or your Eccelency effected somethinge for my releife. I had thought with joy to have presented my service unto you, and now am sory instead thereof to putt your Eccelency to the troble I knowe ye take for me. The ill diett I have heare and the wors usadg hath produced this ill effect that now these two nights I have had a sciatique in my right thigh and legs that much discorageth me, and maketh me lame. I would fayne Signor Francesco [Vercellini] would come unto me. I will pay for his coatch and expence, to direct and advise me, and to deliver him the busynes I have to him from my lord Embassador and the letters I have els to Venis; and yf he bring my freedom with him, I shale have the more joy; yf not, he may gett me heare some garden house, with fier, bed, and other necessaryes, least I fale wors. Yf his being there effect better for me, then that som man be hired theare to com and goe between, by whom I may heare often what is or can be done, and may certefy me of the receyte of my letters att the least, that I may heare what I may hope or looke for.

"1636, Aug. 12-22, Friday, Treviso.—Although I know your care and dilligence for my liberty, and make noe dowte butt your Eccelency doth what is possible and omitteth noe occasion, yett the longing I have to be out of this thraldom and the dayly hope from you maketh me soe often look oute as having not heard from you sinse your man was with me (on Satterday last), I desier much to know how the case standeth, what is the cause, what I may expect. ..... I hoped much on your Eccelencys complaynt to the Colledg butt now because I heare not I dowte much least they neglect you too. I have now been heare 10 dayes and my *fede* giveth me testimony of health for 40 days almost before that, soe that I cannot guess other than sum malis in this, considering with what cruelty and severity they have proceeded with me. My sciatiq which I gott heare by injurious lodging I thanke God mendeth well. ..... Even as this morning I had finished thes lines, came one from this podesta to vew us how we weare in health and sayth within these 2 dayes we shale have liberty, butt what trust may be given to there words I cannot tell. I fear it is but a shuffel to deteyne me heare yett a weeke longer, which is the extremity they doe to the worst *fede* and meanest man.

"1636, Aug. 13-23.—My sweete Lord, becaus I see heare nothing, nothing butt injury, deceyte, and jugling every day this eleven days, that to-morrow and att night and to-morrow and shortly I shall be released, and doe not heare from Venis any certenty by any hand; and I ley heare in a miserable case; I pray pardon me yf to your Eccelency I seme in this often sending importune; eccept by your Eccelency his means (in whom is my only hope to gett release from these barbarous oppressions) they delight hear soe to exercise there tirenny as I am likelye for every day they promise a weeke.

"1636, Aug. 16-26, Treviso.—I wrote to your Eccelency yesterday what a heavy messadg these of the Sanita hear delivered to me from the Senate att Venis, which was that I must stay heare yett until farther order; and asking how long, they sayd seven or ten or twenty dayes, soe I perceyve they doe butt abuse your Eccelency to beare you in hand that every day I shale have my liberty, and therein they betray me and make me loose my time, with whom yf they had delt playnly and rowndly I mought have gone back att the first to Villach and from thence to Gorilia, and there gotten shipping and beene by this time at Rome or Florence, and sene your Eccelency and dispatched my bysines at Venis comming back. Now yf I stay a weeke or ten dayes more heare I shall loose soe much time as the intent of my jorney wilbe broken, and I must retorne without going farther. Good my lord, I beseech you, putt them spedily and rowndly to it, ether that I presently goe (having now beene 15 days) or that I may retorne, which is a thinge is usuall heare, and a little while agoe they did it, sending ther officer with them untill they weare out of their territorye, and in justice they cannot deney your Eccelency one of these and indeed nether, yf ether they did respect anythinge your intercession or would doe justice. I perceyve I am fallen into the handes heare of most base and evel people, and now they begin to accuse one an other, and when I ask them the cause of my stay they forge lyes, as that I was att Salsburg and that Villach hath the plague, and I know not what, and in this place they have talked soe much that to-morrow and to-morrow I should be free, and when your Eccelency stirred in it, expected noe less than present delivery, that now they begin to disesteeme what your Eccelency's favour can doe for me. ..... I never longed for anythynge in all my life soe much as any way and on any condition to be gone from this base place and barbarous people and fearing lest I should be sick and then they would crye me into the plaug and keep me and cheate and tyrunise ove me. God knoweth how long Signor Francesco was with me on Sunday last and tould me (I humbly thanke you) with what desier and ernestnes your Eccelency dealt for me, and that ye hoped every day; butt other perticulars I could not learne by him, nor since."

After the foregoing there are no more letters from Treviso, nor any record of Harvey's departure from the lazaretto, but there is a note from him to Lord Feilding, dated Sept. 7th-17th, 1636, at Florence, from which it appears that he had been for some time at liberty and was then enjoying "much contentment with health and mirth" and receiving many attentions from the Grand Duke, who had himself shown him many of his rarities and treated him with great favour. One more letter, dated in November, announced his arrival at Ratisbon, where he rejoined Lord Arundel and with him travelled home to England.

A WARNING.

To the Editor of THE LANCET.

SIR,—I wish you would insert in the next issue of your journal a note warning your readers, and especially Edinburgh teachers and graduates, that an impostor is writing on my behalf or in my name asking financial assistance, and as a result has, I understand, been assisted. His proceedings, to my intense annoyance, have assumed wide scope, and I would be glad if anyone who receives one of these letters would communicate with me at once. Thanking you in anticipation, I am, Sir, yours faithfully,

Sudbury, near Harrow, Oct. 3rd, 1911. ROBT. H. MARTIN.

AN INTERESTING NOTE.

To the Editor of THE LANCET.

SIR,—On June 29th, 1911, Thomas Bailey, fisherman, aged 34 years, and his son, aged 13, fell overboard at the mouth of the Ouse. Both were drowned. The father, who could swim, tried to rescue his son, who could not. The bodies were recovered from the water on July 7th, I held an inquest on the body of Thomas Bailey on July 8th, and saw the body and examined it. He died *fascino recto*.

I am, Sir, yours faithfully,

EDWARD M. BELOE, Borough Coroner, King's Lynn.

King's Lynn, Sept. 27th, 1911.

A.B.—In each case the fee belongs to the principal unless a special arrangement has previously been made.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

A DIARY OF CONGRESSES.

WE shall publish this diary from time to time that our readers may have under their hands the dates of the approaching scientific Congresses. It is unnecessary to issue the lists of all these functions week by week, and we propose to make only such gatherings as will occur in the immediate future the subject of regular announcement. The following Congresses, Conferences, and Exhibitions are announced for October, 1911:—

April–October.—Rome Exhibition (United Italy's Jubilee).
,, 29th–Oct. 26th (Turin).—International Exhibition.
May 3rd–Oct. 31st (Glasgow).—Scottish Exhibition.
,, 6th–Oct. 31st (Dresden).—International Hygiene Exhibition (British Section opens June 14th).
May 12th–Oct. 31st (London, Crystal Palace).—Festival of Empire Imperial Exhibition. (Profits to King Edward VII. Hospital Fund.)
May 18th–October 31st (London, Shepherd's Bush).—Coronation Exhibition.
Sept. 19th–Oct. 31st (London).—Earl's Court Exhibition.
,, 23rd–Oct. 21st (London, Olympia).—Electrical Exhibition.
September–November (Antwerp).—International Exhibition of Alimentation, Brewing, Wines, and Liqueurs.
Oct. 2nd–7th (Dresden).—Third International Housing Congress.
,, 2nd–7th (Paris).—French Congress of Surgery, Twenty-fourth Annual Congress.
,, 5th–7th (Paris).—Fifteenth Meeting of the French Association of Urology.
,, 6th and 7th (Paris).—French Association of Pediatrics.
,, 9th–12th (Turin).—Twenty-first Congress, Italian Society of Internal Medicine.
,, 9th–13th (Cologne).—Seventh International Congress of Criminal Anthropology.
,, 10th (Paris).—International Sanitary Conference (to Revise the International Sanitary Convention of 1903).
,, 12th–18th (Rome).—Fifth Annual Meeting of the Italian Society for the Advancement of Science.
,, 13th–16th (Turin).—Third National Congress of Professional Diseases.
,, 15th (The Hague).—International Opium Conference.
,, 20th–22nd (Roubaix).—Second National Congress of the Mutalité Maternelle.
,, 22nd and 23rd (Lyons).—Twelfth French Congress of Medicine.
,, 25th–27th (New York City).—Annual Conference of Sanitary Officers of the State of New York.
,, 26th–28th (Rome).—Congress of the Italian Society of Laryngology, Otology, and Rhinology.
,, 31st–Nov. 4th (London, Royal Horticultural Hall).—Twenty-second Universal Cookery and Food Exhibition.
October (Paris).—First Congress of the International Medical Association for the Prevention of War.
,, (Stoke-upon-Trent).—Church Congress.

METEOROLOGICAL READINGS.

The following journals, magazines, &c., have been received:—Dominion Medical Monthly, Middlesex Hospital Journal, St. Louis Medical Review, Archives of Pediatrics, Ash's Monthly, The Prescriber, Journal of the Royal Sanitary Institute, Indian Medical Gazette, Medical Record, Therapeutic Gazette, Bodenreform, Australasian Medical Gazette, Mercy and Truth, Review of Neurology and Psychiatry, British Journal of Dental Science.

Medical Diary for the ensuing Week.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 15, Cavendish-square, W. (temporary address during building of new house).

FRIDAY.

GENERAL MEETING OF FELLOWS at 4.45 P.M.
Election of Candidates for Fellowship.

CLINICAL SECTION (Hon. Secretaries: James Galloway, Charles H. Fagge): at 8.30 P.M.

Cases:
Dr. H. D. Rolleston and Dr. W. P. Tindal-Atkinson: Case of Spondylose Rhizomelique.
Dr. W. Essex Wynter and Dr. J. Murray: Case of Toxic Cirrhosis with Spleno-portal Thrombosis (Banti's Disease); treated by Femoral Drainage.
Dr. James Galloway: Case of Intractable Neuralgia with Myoma Cutis.
Mr. R. C. Elmslie: Case of General Thyroid Malignancy.
Dr. H. Batty Shaw: Case showing Unusual Area of Audibility of a Cardiac Murmur.
Dr. Wilfred Harris: Acute Encephalitis in a Girl æt. 13.
Mr. P. Lockhart Mummery: Three Cases of Excision of the Rectum Three Years after Operation.
Sir Frederic Eve: Case of Resection of a Myeloid Sarcoma of the Tibia with Bone Grafting.
Dr. C. Ward: Case of Pseudo-hermaphroditism.

Paper:
Dr. A. Gregor and Dr. Hopper: A Series of Cases of Acute Anterior Poliomyelitis.

MEDICAL SOCIETY OF LONDON, 11, Chandos-street, Cavendish-square, W.

MONDAY.—8 P.M., General Meeting. 8.30 P.M., Dr. J. M. Bruce (Incoming President): Opening Address. Dr. L. Guthrie: Recurrent Jaundice with Pyrexia, Splenomegaly, Anæmia, and Pigmentation of the Skin, in a Girl of 11 Years.

UNITED SERVICES MEDICAL SOCIETY, Royal Army Medical College, Grosvenor-road, S.W.

WEDNESDAY.—5 P.M., President's Address. Major E. M. Pilcher, D.S.O., R.A.M.C.: The New Bullet.

HUNTERIAN SOCIETY, London Institution, Finsbury-circus, E.C.

WEDNESDAY.—8.30 P.M., Council Meeting. 9 P.M., Dr. T. B. Hyslop: Intra-cranial Murmurs and their Relation to Tinnitus Aurium. (First Hunterian Lecture.)

NEW LONDON DERMATOLOGICAL SOCIETY, at the Rooms of the British Dental Hospital (temporary premises), 2, Hampstead-road (Tottenham Court-road end).

THURSDAY.—4.30 P.M., Meeting.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC, 22, Chenies-street, W.C.

MONDAY.—4 P.M., Mr. W. Evans: Clinique (Skin). 5.15 P.M., Lecture:—Dr. E. Pritchard: Convulsions in Infants and Young Children.

TUESDAY.—4 P.M., Dr. H. L. Tidy: Clinique (Medical). 5.15 P.M., Dr. J. Collier: Paralyses which are Apparent at the Time of Birth.

WEDNESDAY.—4 P.M., Mr. J. Milne, jun.: Clinique (Surgical). 5.15 P.M., Lecture:—Dr. G. H. Savage: The Relationships between Neurasthenia and Insanity.

THURSDAY.—4 P.M., Dr. A. Morison: Clinique (Medical). 5.15 P.M., Lecture:—Dr. D. McKenzie: Enucleation of the Tonsils.

FRIDAY.—4 P.M., Mr. G. French: Clinique (Ear, Nose, and Throat).

POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.

MONDAY.—10 A.M., Surgical Registrar: Demonstration of Cases in Wards. Dr. Simson: Diseases of Women. 12 noon, Dr. Bernstein: Pathological Demonstration. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. 2.30 P.M., Mr. Dunn: Diseases of the Eye. 5 P.M., Lecture:—Mr. Edwards: Suppurative Diseases in Connexion with the Anal Canal.

TUESDAY.—10 A.M., Dr. Robinson: Gynæcological Operations. 11.30 A.M., Mr. Etherington-Smith: Demonstration of Minor Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. 2.30 P.M., Dr. Abraham: Diseases of the Skin. 5 P.M., Lecture:—Dr. R. Jones: The Common Varieties of Insanity.

WEDNESDAY.—10 A.M., Dr. Simson: Gynæcological Demonstration. Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. Mr. B. Harman: Diseases of the Eye. 2.30 P.M., Dr. Simson: Diseases of Women. 5 P.M., Lecture:—Dr. Morton: The Use of Solid Carbon Dioxide.

THURSDAY.—10 A.M., Surgical Registrar: Demonstration of Cases in Wards. 12.15 P.M., Lecture:—Dr. G. Stewart: Practical Medicine. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. 2.30 P.M., Mr. Dunn: Diseases of the Eye. 5 P.M., Lecture:—Mr. Baldwin: Practical Surgery. (Lecture I.)

FRIDAY.—10 A.M., Dr. Robinson: Gynæcological Operations. 12.15 P.M., Lecture:—Dr. Pritchard: Practical Medicine. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. 2.30 P.M., Dr. Abraham: Diseases of the Skin. 5 P.M., Clinical Lecture:—Mr. Pardoe: Urinary Surgery.

SATURDAY.—10 A.M., Medical Registrar: Demonstration of Cases in Wards. Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. Mr. Bishop Harman: Diseases of the Eye. 2 P.M., Medical and Surgical Clinics. X Rays. Operations.

LONDON SCHOOL OF CLINICAL MEDICINE, Dreadnought Hospital, Greenwich.

MONDAY.—2 P.M., Operations. 2.15 P.M., Mr. Turner: Surgery. 3.15 P.M., Sir Dyce Duckworth: Medicine. 4.30 P.M., Mr. R. Lake: Ear and Throat. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Ear and Throat. 3.15 P.M., Special Lecture:—Sir Dyce Duckworth: Cirrhosis of the Liver.

TUESDAY.—2 P.M., Operations. 3.15 P.M., Dr. R. Wells: Medicine. 2.15 P.M., Mr. R. Carling: Surgery. 4.15 P.M., Sir M. Morris: Diseases of the Skin. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Skin. 4.30 P.M., Special Lecture:—Dr. C. Hughes: Anæsthetics.

WEDNESDAY.—2 P.M., Operations. 2.15 P.M., Dr. F. Taylor: Medicine. 3.30 P.M., Mr. Cargill: Ophthalmology. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 11 A.M., Eye.

THURSDAY.—2 P.M., Operations. 2.15 P.M., Dr. G. Rankin: Medicine. 3.15 P.M., Sir W. Bennett: Surgery. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Ear and Throat.

FRIDAY.—2 P.M., Operations. 2.15 P.M., Sir J. Rose Bradford: Medicine. 3.15 P.M., Mr. McGavin: Surgery. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Skin.

SATURDAY.—10 A.M., Radiography. 11 A.M., Dr. A. Davies: Pathological Demonstration. 2 P.M., Operations. Out-patient Demonstration:—10 A.M., Surgical and Medical. 11 A.M., Eye.

CENTRAL LONDON THROAT AND EAR HOSPITAL, Gray's Inn-road, W.C.

TUESDAY AND FRIDAY..—3.45 P.M., Mr. C. Nourse: Accessory Sinuses.

ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN, 49, Leicester-square, W.C.

THURSDAY.—6 P.M., Chesterfield Lecture:—Dr. M. Dockrell: Erythema.

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Brompton, S.W.

WEDNESDAY.—4 P.M., Lecture:—Dr. B. Shaw: Anaphylaxis and its Relation to Disorders of the Thoracic Viscera.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, Queen-square, Bloomsbury, W.C.

TUESDAY.—3.30 P.M., Clinical Lecture:—Dr. J. Collier: Diagnosis and Treatment of Meningitis.

FRIDAY.—3.30 P.M., Clinical Lecture:—Dr. J. Collier: Tumours of the Pons.

LANCOATS HOSPITAL, Manchester.

THURSDAY.—4.15 P.M., Mr. E. S. Bishop: Urinary Surgery. (Post-Graduate Clinic.)

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY (9th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (2 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), Gt. Ormond-street (9 A.M. and 9.30 A.M.), West London (2.30 P.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic (2 P.M.), Hospital operations are performed daily.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will insure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free from THE LANCET Offices, have been reduced, and are now as follows:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 1 0	One Year	£1 5 0
Six Months	0 12 6	Six Months	0 14 0
Three Months	0 6 6	Three Months	0 7 0

(The rate for the United Kingdom will apply also to Medical Subordinates in India whose rates of pay, including allowances, is less than Rs.50 per month.)

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied.

SOLE AGENTS FOR AMERICA—Messrs. WILLIAM WOOD AND CO., 51, Fifth Avenue, New York, U.S.A.

ABSTRACT OF AN

Inaugural Presidential Address

ON THE

PAST WORK OF THE OBSTETRICAL SOCIETY OF LONDON, AND THE OBSTETRIC AND GYNÆCOLOGICAL PROBLEMS STILL AWAITING SOLUTION.

Delivered before the Obstetrical and Gynæcological Section of the Royal Society of Medicine on Oct. 5th, 1911,

BY AMAND ROUTH, M.D. LOND., F.R.C.P. LOND.,

OBSTETRIC PHYSICIAN TO CHARING CROSS HOSPITAL; PRESIDENT OF THE SECTION.

[AFTER thanking the Council and members of the section for the honour of having been chosen their President, Dr. Routh alluded to his having been made a Fellow of the Obstetrical Society of London in 1882 during the Presidency of Dr. Matthews Duncan. Dr. Routh then continued :—]

The Council in that and the succeeding years, 1882 and 1883, contained such honoured names as Arthur Farre, Henry Oldham, Robert Barnes, John Hall Davis, Baptiste Potter, Graily Hewitt, Braxton Hicks, William Priestley, Edward John Tilt, Spencer Wells, Charles J. Cullingworth (then of Manchester), W. S. Playfair, Henry Bennet, J. H. Aveling, Gustavus Murray, George Roper, Knowsley Thornton, and my father, C. H. F. Routh. All these obstetricians have passed away, but their works live after them, and we as their successors continue to hold them in high esteem.

Fortunately, some on the 1882–83 council still live and are equally held in our affection and estimation: John Williams, Henry Gervis, Alban Doran, Clement Godson, Edward Malins of Birmingham and William Stephenson of Aberdeen: with George E. Herman and A. L. Galabin, then the honorary secretaries; and Francis Champneys, then honorary librarian. I am sure that those of that small band who are with us to-night will agree with me in saying that the members of our present amalgamated section are as well fitted as their predecessors to maintain the prestige and good work previously done by the older societies. Indeed, I doubt if at any time in our history we have had such enthusiastic workers in both the pathological and clinical aspects of our specialties as we have had during the last few years.

The Obstetrical Society was founded at an inaugural meeting at the Freemasons' Tavern on Dec. 16th, 1858, nearly 53 years ago. No member of the original Council and only two of the Society's original Fellows, Henry Walter Kiallmark and David Lloyd Roberts, survive. The former, though in poor health, is still keen for all that concerns his profession, and the latter, who performed his first Cæsarean section in 1867, was able to record a successful one only three years ago (Dec. 30th, 1908)—after 40 years' hard operative work. May our salutations go to these two grand veterans of science!

I may refer to three important movements which during the last ten years have proved very advantageous to our interests. One was the formation on the initiative of Dr. Walter Griffith in 1901 of a standing pathological committee to which specimens of doubtful or interesting pathology are referred by the President. The chairmanship of the committee was held by Mr. Alban Doran till 1904 and since then by Dr. Walter Griffith, and these gentlemen with a committee of able and keen pathologists have done excellent work for the section and for science. Another most important event in the history of the Obstetrical Society was the decision made in February, 1902, to admit ladies as Fellows. We were the first important society to do this, and the results have abundantly justified the innovation. The third event was the happy amalgamation of the Obstetrical Society of London and the British Gynæcological Society in 1907, and the formation of the Royal Society of Medicine with the amalgamated societies as one of the sections.

THE PAST WORK OF THE OBSTETRICAL SOCIETY OF LONDON.

Since the inauguration of the Obstetrical Society in 1858 it has been concerned with the advance of obstetric and gynæcological medicine in two main directions: First, by exercising a socio-political influence; and, secondly, by its more normal scientific work.

As regards its socio-political work its greatest success has been the persistent agitation which it has successfully employed in favour of improved obstetric teaching, both of students and midwives, and it has thus been able as a direct result to help to lessen the terrible infantile death-rate and maternal puerperal mortality which then obtained. This has been done (1) by stimulating the teaching and examining bodies to insist upon the better education of medical students in obstetrics; (2) by constantly urging the Government of the day to educate and register midwives; and (3) by actually providing for the education and examination of midwives till Government itself took the matter in hand. Many of our younger members hardly realise how great an influence the Obstetrical Society has had in the improvement in obstetric training. I propose, therefore, for a few minutes to give a short review of this part of the work of the Obstetrical Society.

Defective Obstetric Training.

In 1860[1] Dr. Edward Rigby, the first President, stated that the Council had presented a most important memorial to the General Medical Council urging upon them the imperative importance of improving obstetric education. At the London University students had then only to attend six labours, and attendance at lectures on midwifery was not compulsory. At the Royal College of Physicians of London there was no examination in midwifery, no obstetric expert being then on the Examining Board. At the Royal College of Surgeons of England candidates had to attend three months' lectures on midwifery, but need not have personally attended any confinements. The Obstetrical Society demanded that the standard of education and examination on midwifery should be as high as that which obtained in medicine and surgery. The immediate result of this memorial was that in the following year the Royal College of Physicians of London arranged to examine and grant a licence in medicine and midwifery, and attendance on a course of midwifery and on clinical diseases of women was made compulsory.

Another result was the institution of a new office in our educational hospitals—namely, that of "obstetric physician," whose duties were at first entirely those of an accoucheur, surgery being practically excluded.

In 1863 the President, Dr. Tyler Smith, urged that obstetric physicians should be allowed to perform the operation of ovariotomy, till then mainly in the hands of surgeons. It was, indeed, many years before obstetric physicians were treated with the respect they deserved. In 1879 we find the President of the Society, Dr. Playfair, deploring this, and alluding especially to the fact that in such a representative body as the General Medical Council there was no representative of obstetrics. As many Past-Presidents had done, he deplored the inadequate education in obstetrics and gynæcology as then required by the examining bodies. He urged that it was the duty of the society to agitate upon the question and not to rest satisfied until midwifery was placed on an equality with medicine and surgery. One of the most forcible inaugural addresses was given by Matthews Duncan when our President in 1881. He alluded especially to the efforts of Dr. Playfair in England and of Dr. Macnaughton Jones, our own immediate Past-President, in Ireland, towards the improvement of teaching in midwifery and gynæcology, and, Dr. Matthews Duncan added, with, I think, a marvellous prevision, "that without an extension of the curriculum to five years, he thought that such an improvement was impracticable." As the first step to progress being made, he again urged that an obstetric physician should be placed on the General Medical Council, and he stated that the Council of the Obstetrical Society had again memorialised the Government on the subject. We may congratulate ourselves that very soon after that deputation the Government (April 20th, 1883) realised the necessity of acceding to our Council's request, and that the first representative on the General Medical Council should have been so able an

[1] Transactions of the Obstetrical Society of London, vol. ii., p. 3.

obstetrician and so expert an educationalist as Matthews Duncan himself.

In 1901 Sir John Williams was appointed Crown representative, and on his retirement this year Sir Francis Champneys was appointed by the Crown.

As a result of obstetric experts being now on the General Medical Council and on all examining boards great improvement has taken place in the teaching of clinical midwifery, especially as regards the attendance of the medical student in lying-in wards. This course was strongly advocated by Dr. W. R. Dakin in his presidential address in 1905, which was given at the psychological moment, for it more or less voiced the opinion of everyone concerned, and the teaching of practical midwifery has now been put on a sounder basis. When all the teaching hospitals can either have their own lying-in wards, with efficient resident teachers, or can utilise adjacent adequately staffed lying-in hospitals, all students will get efficient training. The advantage, however, to the student, in view of his future practice, of attending outdoor maternity cases after he has acquired the knowledge of aseptic midwifery in lying-in wards is also obvious, and should not be allowed to be entirely superseded.

Infantile Mortality.

From the first the Obstetrical Society did what it could to lessen infantile mortality, especially during the "puerperal month," and in 1875 issued rules for the "management of infants," which might be advantageously reissued now.

Much has been done by Sir Francis Champneys and others to save the lives of children born asphyxiated, and Dr. Herbert Spencer has demonstrated that many stillborn or newly-born children die from cerebral and other hæmorrhages. Papers, too, have been read on gynæcological troubles in young children, by Dr. Drummond Robinson on Vulvar Discharges in Infants, by Mr. Sydney Stephenson on Ophthalmia Neonatorum, and on Grape-like Sarcoma by Mr. Henry Curtis and Dr. Herbert Williamson. We have, however, mainly concerned ourselves with fœtal monstrosities, hermaphroditism, and other developmental abnormalities, rather than with the causes, pathology, and treatment of the diseases of the child before and after birth. We know little more of the causes of intra-uterine death of the fœtus than we did when Sir W. Priestley, a past-President of the Obstetrical Society, read his Lumleian lectures on that subject in 1887 at the Royal College of Physicians of London.

Mortality both in utero and soon after birth is still far larger than it should be. Sir W. Priestley calculated that in 1887 in London alone 9000 *abortions* occurred annually due to preventable causes. There is no reason to think that abortions are now less numerous or relatively less preventable than they were. The number of *stillbirths* could then only be guessed at, but we can now, thanks to the Registrar-General's statistics, estimate their frequency with fair accuracy. In 1910, 2312 stillbirths were notified in London, representing 2 2 per cent. of the total births. If this proportion holds good for the whole of England and Wales, the stillbirths in 1910 were 19,736. Our knowledge of practical midwifery tells us that many of these stillbirths occur during delivery, and are preventable. At that date, 1887, the infantile death-rate in England and Wales during the first year of life was 145 per 1000 births. In 1909 the rate had been reduced to 109 per 1000 births, a saving of 36 infants per 1000 births, or a saving of 33,922 infants in 1909 in England and Wales and of 5939 infants in London alone. In 1910 the death-rate was 106 per 1000 births. In order to emphasise the special import of this mortality to our section I append Table I. in which it is shown by the Registrar-General that out of 99,430 infants who died during their first year in England and Wales in 1909, 24,686 infants, about *one-fourth, died during the first three months of life from causes connected with birth.*

TABLE I.—*Infantile Deaths in England and Wales in 1909 during the First Three Months of Life from Causes connected with Birth.*

—	Males.	Females.	Total.
Premature births	10,108	7,899	18,007
Congenital hydrocephalus... ...	41	31	72
Other congenital defects	2,072	1,661	3,733
Injury at birth	564	390	954
Atelectasis	874	631	1,505
Want of breast milk	248	167	415
Totals	13,907	10,779	24,686

Another "cause connected with birth" of both infantile death and local inflammatory processes in new-born infants is "obstetrical infection" at birth. Such infection must be distinguished from congenital infection of the infant, conveyed through the mother, such as syphilis, small-pox, measles, malaria, &c. "Obstetrical infection" of the infant due, for instance, to the liquor amnii being infected before birth, in some cases even when the amniotic sac is intact, is as definite an infection as the ophthalmia of vaginal gonococcal origin. It is not yet well recognised in this country that such infection may be the cause of serious or fatal sepsis of the mouth or nose, which by penetration into the lungs or alimentary canal may cause bronchitis or bronchopneumonia, vomiting, gastro-intestinal disturbances, jaundice, &c.

The following table (Table II.), taken from the statistics of the Registrar-General for 1909, shows that *from all causes*, 11 children out of 1000 births die in the first 24 hours of life, 30 children die in the first fortnight, and about 40 in the first month, 109 dying in the first year.

The accoucheur is responsible for the new-born child during at all events the first fortnight of life, and in that period nearly one-third of those children who do not survive their first year lose their lives.

TABLE II.—*Infantile Deaths to 1000 Births at Different Ages from All Causes in 1909 in England and Wales.*

Die during the first 24 hours		11·5	per 1000.

,, ,, second week		5·7	,,
,, ,, first fortnight		30·3	,,
,, ,, first month		39·75	,,
,, ,, the first year of life		108 73	,,

Can we not, as the Obstetrical Section of this great society, do something more to lessen this infantile mortality by encouraging the education of women in the rational management of themselves and their children during the puerperium? As showing what can be done by definite special effort to encourage lactation and discourage artificial feeding of infants, I may quote results in St. Pancras and Stepney. In St. Pancras Dr. J. F. J. Sykes and the municipal health authorities began their educational experiment in 1904, when the infantile death-rate was 151 per 1000 births. Last year it was 107 per 1000. In Stepney, under similar circumstances, it dropped from 138 to 109 per 1000 births. Unfortunately a concrete example shows the converse of this progress. We have recently had a combination of drought and railway strikes which shows in a most graphic way how infants who are not breast-fed die wholesale if cow's milk be deteriorated by bacteria-dust, or if, owing to milk from the suburbs failing to be delivered in the large cities, infants have to be fed on other articles of diet. (See Table III.)

TABLE III.—*Deaths of Children under One Year to 1000 Births in London and Liverpool (1911).*

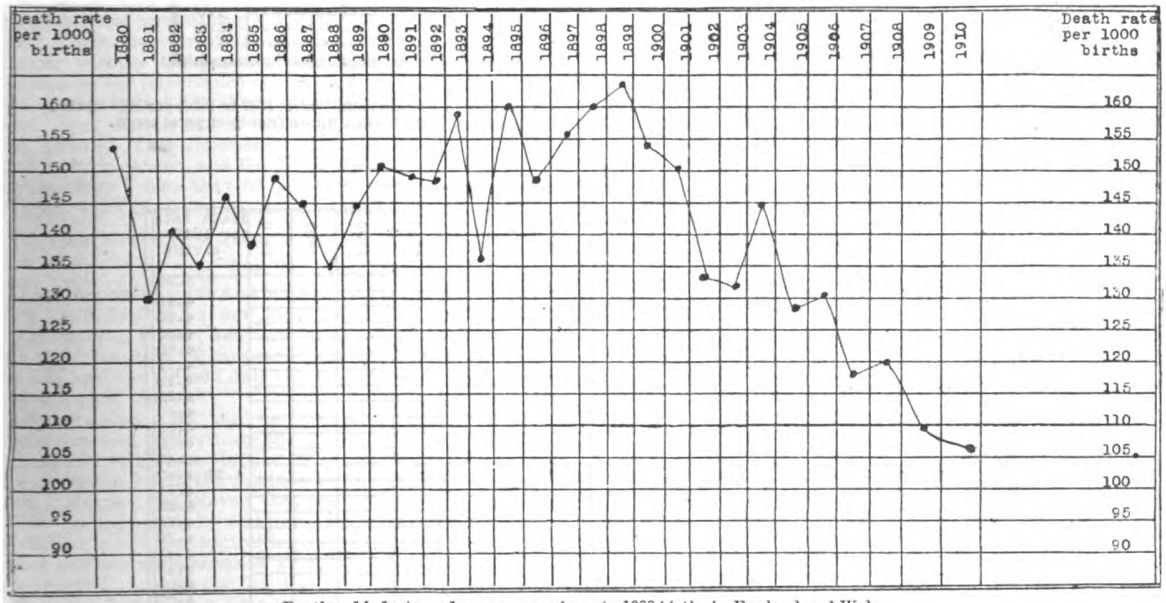
,, 16th	1997	442	221	,, 16th	381	107	281



The table shows that in London in the week ending July 15th, 1911, the deaths of infants under one year of age was 150—67 per 1000 births; in the weeks ending August 12th and 19th, when the great heat and the railway strike were in action, the infantile deaths rose to 636 and 705, or 338 and 305 per 1000 births. In Liverpool, where the railway strike was more general and the absence of milk, or its deterioration from delay, was more universal, the infantile deaths on the same dates rose from 54 to 144 and 165, and the death-rate per 1000 births from 121 to 361 and 445. I suppose no one will dispute the fact that if these infants had been breast-fed this terrible mortality would not have occurred. I quote one of the rules drawn up by the Obstetrical Society in 1873 which would be particularly useful in these days, when mothers so often avoid the duty of lactation for selfish reasons, or prolong the function hoping to postpone another pregnancy. The rule says:—

> Nature provides breast milk as the proper food for an infant, and suckling is by far the best way of feeding it. Provided the mother has plenty of milk and is in good health, an infant requires and should have no other food but the breast milk until about the sixth month.

What a blessing to the new-born would ensue if advisory legislation or custom could make such a practice the rule rather than the exception. Cannot the united voice of this section as well as the advice of its individual members do something to stem the tide of non-lactation, which must act to the physical disadvantage of both mother and child, and which at the same time tends to annihilate the intimate mental, moral, and social ties which should bind mother and child together at the beginning of an infant's life?

I append Diagram 1, showing the steady fall in the infantile death-rate in England and Wales during the last 30 years.

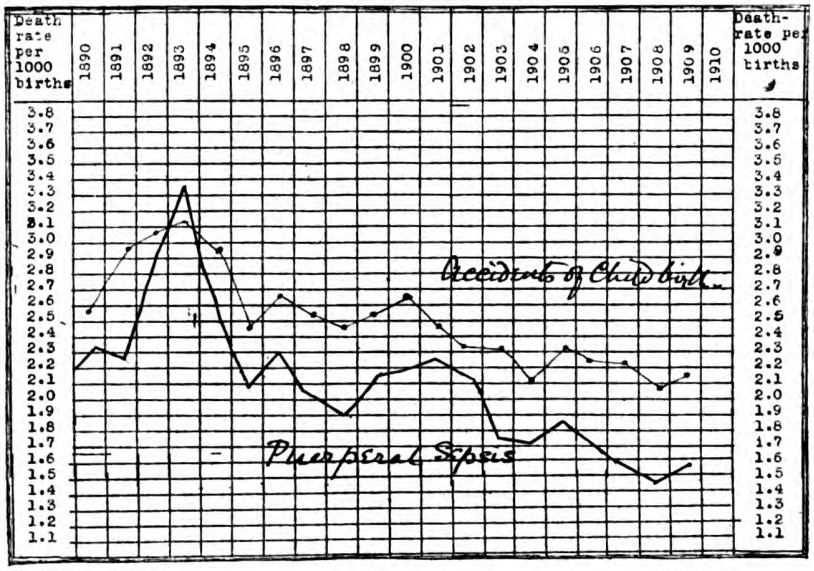
DIAGRAM 1.

Deaths of infants under one year of age to 1000 births in England and Wales.

It will be observed that the infantile death-rate between 1880 and 1900 averaged about 145 per 1000 births, and actually got worse and worse till it reached 163 per 1000 in 1899. Since then it has steadily improved, and last year (1910) it was only 106 per 1000, a saving of life as compared with 1899 of 57 infants out of every 1000 born. I believe this result to be largely due to the compulsory education of midwives which the examinations by the Obstetrical Society of London and the Central Midwives Board have necessitated, for about 21,000 midwives have been examined and passed by these two bodies, and it is stated that half the total births are attended by midwives.

Puerperal Fever.

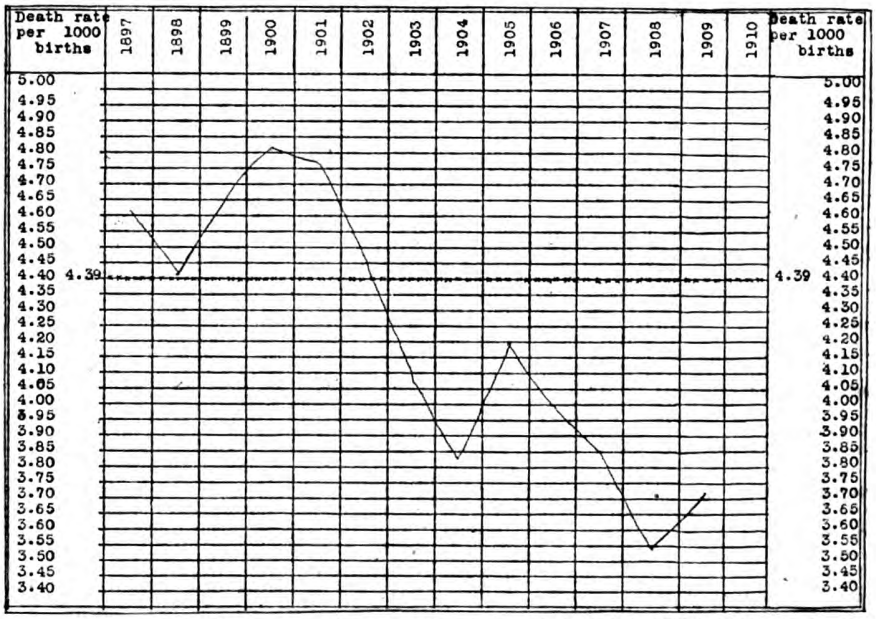
The prevention of "puerperal fever" has been a burning question since the foundation of the Obstetrical Society, and in 1872 a strong standing committee was appointed "for the collection of observations on temperature during pregnancy, parturition, and the puerperal state." By this and various other methods the Obstetrical Society has constantly and consistently endeavoured to save the lives of parturient women, not only by its scientific work, but by endeavouring to get the importance of the science and art of midwifery recognised by medical opinion and by Government and the country generally.



We can now see that a definite improvement has within the last few years taken place in the death-rate due to septicæmia. Undoubtedly the modern conduct of maternity cases in lying-in institutions has led not only to an enormous diminution of the mortality and morbidity due to sepsis in those institutions, but their success has shown what can be done also in general practice. In 1865–1875 the British Lying-in Hospital had a death-rate of 19·4 per 1000; City of London Lying-in Hospital, 14·3 per 1000; and Queen Charlotte's Hospital, 22·3 per 1000. In the Rotunda, Dublin, the death-rate between 1811 and 1875 varied from 13·1 to 32·7 per 1000. The mortality was, however, not always so great, for in some decades even 100 years ago the death-rate in lying-in hospitals was remarkably low from unexplained causes; thus, in the British Lying-in Hospital between 1790 and 1800 the death-rate in 6677 deliveries was only 3·2 per 1000, and at the same date the mortality at the City of London Lying-in Hospital was only 5·7 per 1000. Explanations of these good years in puerperal fever statistics are difficult, but the invariable rapid return of bad years prior to the routine use of antiseptics showed that when septicæmia once developed in a lying-in hospital none of the methods then in use served to check its spread, and as a rule the lying-in hospital had for a time to be entirely closed and redecorated. As late as 1889 Dr. Galabin in his inaugural address as President, when speaking of antiseptics in midwifery, said: "The hope may now be entertained that modern antiseptic methods will suffice to render healthy even a lying-in ward in a general hospital, though it is premature to speak positively on the subject until the experiment has been tried." The experiment has now been tried and has proved completely successful, and lying-in wards in our London and provincial hospitals give us no anxiety.

The question as to how far antiseptic and aseptic midwifery has reduced puerperal mortality and morbidity in general practice is more difficult to decide. Dr. Galabin gave the mortality of childbirth between 1847 and 1885 as 4·82 per 1000 births, and 4·45 between 1875 and 1885, more than half of these deaths being due to puerperal fever. Dr. Cullingworth showed in his inaugural address that the death-rate of puerperal septicæmia in 1896 was not falling

but actually rising. The death-rate in England and Wales from accident and septicæmia in the five years ending 1895 was 5·4 per 1000 births; from septicæmia alone, 2·5 per 1000. When all qualified medical practitioners and midwives practising midwifery have been trained in modern midwifery methods sepsis should be banished.



In Diagrams 2 and 3 it will be seen that not only is the proportion of deaths in England and Wales from "puerperal septic diseases" becoming reduced in comparison with the deaths due to other "accidents of childbirth," but that the actual death-rate from puerperal septicæmia is steadily becoming reduced; whilst, curiously and suggestively, the death-rate from other "accidents of childbirth" is stationary or only slightly diminishing. Does this mean that operative midwifery and measures taken to avert sepsis have not tended to lessen deaths due to other "accidents of childbirth"? It is only right that we should consider this possibility, though time does not now permit me to do so, for it would not be to the credit of the profession if it succeeded in its effort to annihilate sepsis, only to add to the maternal risks in other directions by anything like unnecessary interference with the natural process of parturition. In London deaths from "accidents of childbirth" show a much greater relative decline than in England and Wales. Members of the section will agree with me that Diagrams 2 and 3 are, on the whole, very satisfactory evidence of success achieved.

DIAGRAM 2.

Death-rates from puerperal sepsis and from accidents of child-birth respectively in England and Wales, 1890 to 1910, per 1000 births. Dotted line indicates death-rate from accidents of child-birth. Thick line indicates death-rate from puerperal sepsis.

DIAGRAM 3.

Death-rates in England and Wales from puerperal sepsis and accidents of child-birth, 1897 to 1910 inclusive, to 1000 births. The dotted line shows the average death-rate (4·39) for the ten years 1897–1906.

Notification of Cases of Puerperal Septicæmia.

Complete or reliable information as regards the number of cases of puerperal septicæmia in England and Wales has been very difficult to obtain till now, as notification has not been enforced. In future there will be no such difficulty, for a General Order was issued by the Local Government Board on Dec. 13th, 1910, requiring *every* medical officer of health to send in weekly returns of notified infectious diseases, including puerperal fever. Returns are accordingly now received every week from the majority of the 1800 sanitary districts in England and Wales. During the first six months of 1911, 1013 cases of puerperal fever were notified in England and Wales; and 145 cases in London, where there were 68 deaths, a death-rate of 46·9 per cent. of the cases notified.

Other Medico-Political Suggestions.

Other medico-political suggestions have been made from time to time by presidents of the Obstetrical Society. I will only mention two.

Dr. Matthews Duncan in 1881[2] urged that women about to be married should receive legislative protection from syphilis—that, in fact, it should be criminal for a man to marry who had recent or active syphilis. He also wished it to be considered criminal for a woman who has syphilitic sores on her pudenda to fail to warn her accoucheur of the circumstance. He instanced an accoucheur who only survived 18 months after attendance upon such a case.

Dr. Herbert Spencer in 1907[3] suggested that in order to ensure cases of uterine cancer coming earlier under treatment two definite steps should be taken: (1) to diffuse the knowledge of the symptoms of the disease among women, as has been done with good results in Germany; and (2) to urge upon general practitioners that it is a neglect of duty to treat hæmorrhage or discharge which may be due to uterine cancer without making or advising a local examination. To emphasise the importance of such a step I may state that in the years 1901–1909 152,737 women over 25 years of age died from cancer, and of these 35,516 died from cancer of the uterus. This represents 23·2 per cent. of the total deaths from cancer, and Dr. T. W. Eden in his "Manual of Gynæcology" says that 96 per cent. of these are cervical cancer, 4 per cent. cancer of the body of the uterus.

THE FUTURE OF OBSTETRICS AND GYNÆCOLOGY.

I.—*Obstetrics.*

I am becoming more and more convinced that we shall get very little further in our knowledge of the physiology of menstruation, labour, and lactation, and of the causation of the toxic diseases of pregnancy and the puerperium, unless we call into our aid not only the bacteriologist but also the physiological chemist.

Menstruation.—At the very beginning of our study of obstetrics and gynæcology the subject of menstruation has necessarily to be considered. We know very little either of the causation or of the significance and utility of menstruation. Heape[4] has proved that the pro-œstrum stage of the "rut" in animals is homologous with menstruation, and that ovulation is not the controlling factor, and as a result the nerve and ovulation theories as to its cause are now largely surrendered in favour of the theory that its cyclical occurrence is due to a recurring bio-chemical change in the blood. One of the elements in this change appears to be an excess of the salts of calcium, a fact put forward in our Section by Dr. Blair Bell[5] who considers that the uterus of woman is homologous with the calcium chamber of birds and that the calcium metabolism is largely influenced by the internal secretion of the ovary and of the other ductless glands. The whole subject is still obscure and awaits solution at the hands of physiological chemists.

Labour and lactation.—Both labour and lactation can proceed normally without spinal nerve influences, as I showed in a case of traumatic paraplegia. What is the chemical substance which is thrown into the blood stream by uterine or placental metabolism at, or soon after, parturition, and which causes the mammary glands to secrete milk and the liver to secrete glucose to supply that milk with sugar? Is this chemical substance identical with that which starts the onset of labour.

Lutein tissue.—What, for instance, is the influence exerted by lutein tissue? Dr. Cuthbert Lockyer and others have done much to answer this question from the clinical and pathological standpoint. What is its action upon the health of the individual? What is the influence which its excess or diminution has upon the dates and occurrences of such functions as menstruation, ovulation, and the menopause; and on fertilisation, the implantation of the ovum, labour, and lactation? Is lutein tissue one of the essential bio-chemical products, one at all events of the ovarian internal secretions, which by getting into the blood exerts a controlling or exciting functional influence until recently unsuspected?

Physiological chemistry is an extremely difficult science, and none but experts can tackle it. Those interested in the subject should read Dr. A. E. Garrod's paper on "Where Chemistry and Medicine Meet."[6] So difficult is it that it seems to me that until we have chairs and laboratories specially instituted for the study of these branches of biological chemistry in our teaching schools we shall get very little beyond our present scanty and clouded knowledge, not only of the cyclical occurrence of the functions named, but also of the toxæmias of pregnancy and the puerperium. We know nothing of the chemical constitution of the toxins producing hyperemesis gravidarum, albuminuria, eclampsia, the diabetes of pregnancy apart from ordinary glycosuria, the chorea of pregnancy, acute yellow atrophy of the liver, and puerperal insanity. Are these toxins produced from the ovarian or the placental metabolism? What can be the explanation that injection of solution of iodide of potassium into the breasts or amputation of the breasts, as performed by Sellheim, can cure eclampsia?[7]

Amputation seems a brutal operation, yet is it possible that there is a theoretical justification for it, and that the internal secretion of the mammary glands is liable to change and become toxic and cause eclampsia. Dr. Herbert Spencer kindly referred me to his brother, Mr. Trevor Spencer, M.R.C.V.S., of Kettering, who tells me he has seen about 1000 cases of "drop" or "parturient apoplexy" in cows, due, it is supposed, to a toxin developed in the mammary gland. The disease comes on, as a rule, on the first or second day after labour, and used to be almost invariably fatal, but now 98 per cent. of cases are cured within a few hours after an antiseptic solution, followed by air or oxygen, has been freely injected into each quarter of the udder.

We know absolutely nothing of any specific means of treating puerperal fever, although we believe that we know the various specific germs which produce it. Yet how is it that polyvalent serum prepared from streptococci obtained from many cases of puerperal septicæmia is so very seldom successful, and, indeed, serum-therapy seems only really successful, even when a streptococcal infection seems certain, in cases where pus has already formed in the pelvic cellular or perimetric tissue, and to some extent, therefore, localised the infection. As I suggested in my Cæsarean Section monograph,[8] can no way be found by which the infecting germ can be discovered at the onset of infection by differential staining, &c., without waiting for a culture diagnosis? Can no more rapid way than is now possible be then found by which a serum or a vaccine can be made from the patient's own brand of streptococcus or other germ thus found, and so, perhaps, save her life? Or is there some other fact of which we are now ignorant to explain our failure to cure these septic cases by a specific antitoxin? I believe that for some days after infection puerperal septicæmia most frequently remains only a local infection in the uterus and its veins. At present, therefore, I personally rely with much greater confidence upon clearing out the uterus and swabbing with strong iodine solution, and giving large doses of liquor ferri perchloridi to increase the general resistance, rather than upon any attempt to combat the infection itself.

The failure of bacteriological treatment in puerperal[9] septicæmia is all the more disappointing when we see how similar treatment answers for allied conditions. For instance,

we know the good results of vaccine therapy in cases of chronic gonorrhœal cystitis, endometritis, and salpingitis, and I have seen two cases where vaccine prepared from the patient's own gonococci was used during subsequent attacks of acute salpingitis, the attack in each case subsiding at once, contrary to the opinion generally held.

After careful work Dr. A. W. W. Lea of Manchester read a paper before this section,[10] and is of opinion that organisms indistinguishable from pyogenic streptococci, together with diplococci and bacterium coli, are not infrequently present in the vagina of pregnant women. The fact is, however, that we are not yet quite sure of the significance of the germs thus found in the vagina at the onset of labour, whether we believe in Döderlein's theory or not. If we were really sure that the streptococci, staphylococci, bacillus coli, &c., present in the vagina of a healthy woman during labour were liable to infect the woman, it would be our duty to disinfect and sterilise the vagina in every case before labour precisely as we do before vaginal operations. Experience appears to show that this is not necessary, and it seems more than probable that the patient is immune from the germs which are habitually present in her vagina, immune in this case apparently by means of Döderlein's bacillus, and that she only becomes infected when germs are introduced from without, germs for which there is not in her own system an anti-body to resist. A man bitten by the teeth of a cat or dog may get a fatal sepsis, yet that cat or dog can freely and advantageously lick its own wounds.

It is known that the serum obtained from a pregnant woman has different qualities from that of other women, but very little is known of the actual and essential differences except as regards the effect upon animals of inoculations of the serum. Physiological chemists have not yet discovered the chemical constitution or molecular structure of the substances concerned. It is said to be possible to diagnose the existence of pregnancy by a serum test founded upon the power of the serum to hinder the action of proteolytic ferments such as trypsin.[11] It is further shown by Krause and Graff[12] of Vienna that during the first eight months of pregnancy placental serum has a remarkable power of destroying cancer cells and of resisting cancer invasion by manufacturing an anti-cancerous substance. Is this a partial explanation of the rarity of the combination of cancer and pregnancy, and perhaps a partial explanation of the improvement which pregnancy usually exerts upon the spread of tuberculosis, and the almost inevitable downward progress due to the disease after labour? In this connexion I may allude to the fact that the presence of pregnancy prevents perfect reliance being placed upon blood-tests in some cases. Thus, according to Stern,[13] local tuberculin reactions are distinctly diminished during pregnancy. In healthy non-pregnant women 65 per cent. gave positive reaction to the cutaneous and 14·5 per cent. to the conjunctival test, whereas in the seventh, eighth, and ninth months of pregnancy the cutaneous reaction diminished to 36, 30, and 28 per cent., and the conjunctival reaction results were consistently negative.

There is reason to believe that pregnant women[14] have some sort of immunity from scarlatina, and puerperal women a special liability to it. Olshausen[15] could only find instances of seven cases of scarlatina during pregnancy, as compared with 134 within one week after delivery. Boxall[16] in a paper read in this Section did not think that this was due to a delayed period of incubation in pregnant women.

Good work has been done in this Section on the physiological action of the placenta by Professor W. E. Dixon and Dr. Frank Taylor,[17] but very much more remains to be done.

I wish to allude to a few instances showing our ignorance as regards the origin of common diseases, for it is mainly the etiology of obstetric diseases which is now puzzling us.

Hydatidiform degeneration of the chorion.—What, for instance, is the cause of cystic degeneration of chorionic villi? We believe it is of fœtal rather than maternal etiology, but mainly because it may occur in one of twins, the other placenta being normal. Wh.. else do we know about its causation? The frequent association of lutein cysts with this condition, and the established fact that destruction of the corpus luteum in rabbits prevents implantation of the fertilized ovum by preventing the development of the trophoblast, has led to the belief that this excess of lutein tissue may be the cause. Perhaps, as Dr. G. F. Blacker suggests, there may be a common cause both of the proliferation of the chorionic epithelium and of the lutein cells. What explanation again have we of the development of chorion-epithelioma? Is there a benign and a malignant hydatidiform degeneration of the chorion? Can they be differentiated? What is there in chorion epithelioma different to other malignant growths, which in some cases enables a timely hysterectomy to cure the patient even when metastatic growths have developed in the lungs? Is there a benign and a malignant chorion epithelioma as has been suggested?

Ectopic gestation.—Are we any more sure of the causes of tubal gestation than we were before Lawson Tait suggested a previous chronic salpingitis?

Phlegmasia alba dolens.—What, again, is the pathology of true phlegmasia dolens (the lymphangitis type)? Is it an infection or a secondary toxæmia? Its sudden, fairly punctual onset, its course and duration, all point to a specific microbic origin.

Pyelo-nephritis of pregnancy.—What is the true explanation of the pyelitis of pregnancy due to bacillus coli infection? And why is the right kidney almost always primarily attacked? Explanations are plentiful, fanciful, and often mutually destructive.

II.—*Gynæcology.*

Inflamed appendages.—Turning now to gynæcology I would like an authoritative paper from one of our seniors as to when a pyosalpinx or a matted tube and ovary, the result of salpingitis, should be operated upon, and when left alone or otherwise treated. Personally I believe that such cases should very rarely be dealt with by abdominal section, and practically never during the acute stage when the pus in the tubes is virulently infective.

Fibrosis of uterus.—What do we know of the pathology of so-called fibrosis of the uterus? There is no doubt it exists, though till lately it was unsuspected. The best account of fibrosis which I have read is in Dr. Eden's "Manual of Gynæcology," but are the microscopical changes described by him infective, inflammatory, or degenerative? In such cases, with our present knowledge, hæmorrhage becomes almost intractable. Can nothing but hysterectomy stop the bleeding? Would Röntgen rays do good?

Menorrhagia of puberty.—What is the explanation of the menorrhagia of puberty, which is sometimes so severe and intractable as to bring young girls almost to death's door? Is it a uterine or a constitutional disease? There is no direct evidence that it is due to a blood abnormality, yet the best remedy in my experience is prolonged treatment with lactate of calcium.

"*Fungous endometritis.*"—I would like this Section or the Obstetric Section of the International Medical Congress, meeting in 1913, to decide that the word "endometritis" should cease to be used for adenomatous overgrowths of the uterine mucosa. Everyone agrees that it is an obsolete and erroneous expression, yet its use is continued, often with the prefix "so-called," or it is put in inverted commas to show its erroneous ambiguity. The main difficulty is to find a word which will cover all the benign varieties of adenomatous overgrowth which would be included, just as the word "adenoids" covers different types of adenomatous growth in the naso-pharynx of children. In this connexion I may mention that I have very frequently found that women from whose uteri I have scraped unusual quantities of adenomatous tissue suffered from adenoids as children.

Vascular caruncle.—What is the cause of vascular caruncle of the urethra? And why is it so prone to recur? How is it that no nerve tissue has been demonstrated in their structure when they are such painful growths?

Fibromyomata.—Dr. Clay of Manchester,[18] a Fellow of the Obstetrical Society of London, read at one of its meetings in 1863 an account of two abdominal hysterectomies with intraperitoneal treatment of the stump for fibroids done in 1844 and 1863, the first performed in this country, one recovering.

[17] Proceedings of the Royal Society of Medicine (Obstetrical Section), vol. i., p. 11.

[18] Transactions of the Obstetrical Society of London, vol. v., p. 58.

A study of the transactions of our amalgamated societies shows the steady progress which has been made, until at the present time mortality after hysterectomy for fibroids is almost non-existent unless the operation has been too long delayed, or unless constitutional or local complications are present.

I am, however, entirely opposed to the view that a fibroid which is producing no symptoms should be removed for fear of symptoms or degenerations which may, or may not, subsequently develop. That is not conservative surgery, and unless the patient is going to the tropics, where fibroids always get larger and where menorrhagia is sure to occur, or unless other special circumstances are present, I do not operate till symptoms arise. We are still ignorant of the causation of these fibromyomata.

In his inaugural address in 1887 Dr. John Williams,[19] as he then was, suggested that just as antiseptics in midwifery at that date had given obstetricians the power to prevent chronic disease and suffering in women, so perhaps in 40 years' time some president of the Obstetrical Society would be able to announce that a means of preventing the growth of ovarian cysts, uterine fibro-myomata, and even cancer, had been found. Twenty-four years have since elapsed. Do we as yet know anything more of the causation of these diseases? All observers seem to think that the starting-point is in or around a small capillary.

Lawson Tait,[20] in 1882, believed that the deranged production of muscle cells which began by a growth near to a vascular supply was due to some error of the nerve influence which he believed to govern menstruation.

Dr. Elizabeth Willey[21] drew attention in a valuable paper at this Section in 1909 to the views of Klebs, Pilliet, and others who believed that fibroids begin in the uterine capillaries themselves. Dr. Willey considers that fibroids originate in proliferating muscle cells developed in vascular tissue, and that the stimulus producing the proliferation has some relation to the activity of the sexual organs. Even, however, if these views are right we need to discover the remote cause, which acting probably through the blood-supply, stirs these muscle cells, grouped round the smaller vessels, into activity. The effect of oöphorectomy and the action of X rays point to the exciting influence being an ovarian (Graafian follicle) internal secretion. Can lutein tissue here again be the starting-point in the development of fibroids?

Cancer of the uterus.—Is anything known of the cause of uterine cancer? Do we realise that in the last nine years over 34,000 women in England and Wales have died from cancer of the cervix uteri? This is at the rate of 3777 deaths a year. Since Sir John Williams's Harveian lectures in 1886, but little has been done to try to find the clinical precursors to cancer of the cervix. Sir John Williams proved that there was no causal relation between cervical laceration and cancer, and considered there was then no available scientific evidence that glandular erosions predisposed to malignant change. Those who have had patients develop cancer of the cervix, whose previous clinical history is known as regards changes in the cervix uteri, might easily help us to obtain evidence on the subject. He quoted the views of Ruge and Veit, who had described cases of glandular cancer originating in erosions, and also described cases of his own where cancer had developed from the deeper glands underlying an erosion, but he had always found healthy gland tissue between the new growth and the papillary glands of the erosion. He had seen no case where the surface glands of an erosion became primarily cancerous.

"Cervical erosion."—Our views as to the significance of cervical erosion will depend upon the views we hold regarding the relationships between this so-called erosion and cancer. Although Dr. Bennet's pathology, nomenclature, and his overdrawn accounts of the conditions were alike wrong, he was the first, as Dr. Watt Black told us in one of his presidential addresses, to discover that pelvic inflammation existed in the non-puerperal state. Has not the pendulum of reaction, due in this case to the exaggerations of the discoverer and the ridicule of his critics, swung too far? Are we correct in our present view that we may safely ignore the existence of an erosion? Have we no evidence that it may predispose at a later date to a less benign proliferation of the underlying glands and of their lining of columnar cells, and be, in fact, an early evidence or indication of a tendency towards epithelioma? Prolonged ineffective treatment of an erosion causes great inconvenience to the patient, and, as Dr. Herman has emphasised, adds distinctly to her nervous tension. What, then, should be our attitude in dealing with cervical erosions? I notice that many advise that erosions should be treated drastically; for instance, by scraping deeply and using the actual cautery. Is this because they have a misgiving that they predispose to epithelioma? I have no real evidence one way or another, and personally do not feel able to dogmatise on the subject.

Dysmenorrhœa.—There is no recognised consensus of opinion on this subject. Indeed, I think views as to dysmenorrhœa are less definite now than they were two or three years ago. What examiner in gynæcology would venture to give a question to-day on the varieties and causation of dysmenorrhœa? The elementary question, "What is dysmenorrhœa?" or even "Whether dysmenorrhœa is a symptom or a disease?" would meet with curiously divergent answers, according to the medical school of the student.

Ovarian papillomata.—What is the explanation of the occasional complete disappearance after an apparently useless laparotomy of large masses of ovarian papillomata which have extensively involved both the peritoneal and subperitoneal tissues, the patient recovering perfectly with nothing but a fibrous body to show where the ovary originally was?[22] In the large majority of such inoperable cases death rapidly supervenes, yet the papillomatous growth is microscopically identical with the cases that recover. In other words, how can we tell when such papillomata are malignant or benign?

The future of gynæcology.—What is to be the future of gynæcology? Is it to continue to become more and more surgical? I think not. Is it not more than possible that in the near future some President of the section will give an inaugural address upon "Treatment Other than Operative in Gynæcology," and will base his remarks upon the wonderful discoveries being made in bacteriological, chemical, electrical, and radiographical therapeutics? Even as it is, without considering these new aids in treatment, is there not a tendency nowadays to consider ourselves surgeons only, rather than a happy combination of physician and surgeon, to advise an operation because it is the easiest way to treat a case, or to operate on the rush of both hospital and private practice without previous adequate constitutional preparation of the patient?

Wertheim's operation.—Are we not also prone to go to extremes in the details of some of our newest methods of operating? I doubt much if Wertheim's operation for the very advanced cases of cancer of the cervix uteri will continue to be considered wise, nor do I think it will continue to be adopted for very early cases, but rather be reserved for those middle cases where the extended operation is likely to be permanently successful, and worth the extra immediate risk, or where in an early case it is doubtful whether a vaginal operation would suffice to remove all affected tissues.

Ventrifixation.—When one hears of the large numbers of cases of ventrifixation being done both in hospital and private practice, and the numerical proportion they bear to other abdominal operations, one ventures to wonder whether those who thus so frequently treat prolapse and retroversion have had any real experience of the advantages during the child-bearing age of vaginal pessaries wisely selected and skilfully applied. I have not come across cases requiring ventrifixation in anything like the proportion that some others have, and I do not know how to explain the difference.

Mortality Statistics.

Why is it that statistics of large series of abdominal operations are not improving during the last few years? Zweifel says that the death-rate from all causes after operation has risen from 5·5 per cent. in the period 1887–92 to 7·8 per cent. in the period 1903–09. No doubt this is partly due to the introduction of such heroic operations as Wertheim's for uterine cancer, but when these operations are excluded the mortality is still 6 per cent. He considers that the increase is mainly due to pulmonary embolism which caused 18 deaths in 1832 operations, and he attributes it to the systematic use of Trendelenburg's position. By avoiding

[19] Ibid., vol. xxix., p. 107.

[22] Amand Routh: Transactions of the Obstetrical Society of London, vol. xlix., 1907, p. 216.

flexure of the legs and lowering of the shoulders he only had three deaths in the following 806 operations. Olshausen agrees with Zweifel in his conclusion.

CONCLUSION.

We are at the beginning of a period when other methods of treatment than surgery are being gradually opened up, but are we not rather closing our eyes to those aids which are already known to us? How many of us have tried to arrest hæmorrhage from fibromyomatous uteri in cases refusing, or unsuited for, an abdominal operation by transferring the patient to our electrical colleagues for exposure to X rays? I have done so in both hospital and private cases, especially at menopause ages, with distinct success. The rays arrest ovulation and the formation of lutein tissue, by action on the Graafian follicles, and arrest the growth of fibroids owing to that action and to special action upon the cells forming the fibroid itself. I have not yet had a chance of using X rays in fibrosis uteri.

Again, do we realise that a tube of radium inserted two or three times for 20 minutes into the crater cavity of an incurable uterine carcinoma in many cases causes complete, though so far as is yet known only temporary, relief from pain and discharge? Are we alive to the remarkable effect of electric heat and light baths, which can be easily applied by fixing electric lamps to the ribs of a bed-cradle? These "baths" speedily relieve pelvic pain and promote rapid absorption of both parametric and perimetric exudation after the acute stage is over.

Dr. Curtis Webb's [23] strong advocacy at our section of ionic medication drew attention to another electro-therapeutic mode of treatment which may prove of much utility in the future.

Bacon said: "The whole art of medicine is observation." Observation in medicine in Bacon's time was almost purely clinical, and treatment largely empirical. The enthusiasm and hard work done by our section, and by our younger members especially, are gradually unfolding the obscurities still remaining in obstetrics and gynæcology. The clinical facts now brought before us at our meetings are not, as in the early days of the society, all that is recorded, but practically every such history is accompanied by a pathological, and sometimes with a bacteriological, report also. These, and the addition in suitable cases, such as the toxæmias of pregnancy, of the report of a physiological chemist, will, I hope, ere long enable us to discover the still unknown causes of the many diseases we daily discuss, to some of which I have referred. And when we know the causation, our efforts, both towards prevention and cure, must have their due reward. The discovery of the toxin in a toxæmic case by means of a perfected physiological chemistry will point to its antidote, and diseases which now find us helpless to combat them will readily yield both to prevention and to treatment, and critical diseases, such as puerperal eclampsia, now treated by such different surgical procedures as Cæsarean section, decapsulation of the kidneys, or even by amputation of the breasts, according to the theory or caprice of the operator, will be successfully dealt with by rational methods. I trust that the Obstetrical and Gynæcological Section of the Royal Society of Medicine will help in no small measure to a solution of the many problems which are still eluding us.

SANATORIUM FOR THE TREATMENT OF TUBERCULOSIS AT WESTON, TORONTO.—In THE LANCET of Dec. 17th, 1910, an account was given of the free sanatorium for consumptives at Weston, near Toronto. Soon after the account was published the greater part of the buildings of this institution were destroyed by fire. That known as the King Edward building, the newest portion, and situated at some little distance from the other buildings, was unharmed. The majority of the patients are now accommodated in the King Edward building, which was designed to hold 30 patients, but now contains considerably more than that number. In fact, the existing accommodation of the sanatorium is not adequate, and steps are to be taken to rebuild on a larger and more substantial scale than formerly. How the money for this purpose is to be raised has not yet been decided upon, but it is stated that a decision will be reached shortly.

Hunterian Lecture

ON

INTRACRANIAL MURMURS IN THEIR RELATIONSHIP TO TINNITUS AURIUM.

Delivered before the Hunterian Society on Oct. 11th, 1911,

BY THEO. B. HYSLOP, M.D., C.M. EDIN., M.R.C.P. EDIN., F.R.S.E.,

LATE RESIDENT PHYSICIAN, BETHLEM ROYAL HOSPITAL; LATE LECTURER ON MENTAL DISEASES, ETC., AT ST. MARY'S HOSPITAL MEDICAL SCHOOL, AND AT THE ROYAL FREE HOSPITAL.

MR. PRESIDENT AND GENTLEMEN,—In selecting "intracranial murmurs" as the subject of this lecture I am fully aware of the difficulties before me. Our knowledge of the various conditions which lead to the subjective appreciation of "tinnitus aurium" is not only very extensive but also somewhat bewildering in its complexity. The term "tinnitus" is applied to certain noises usually heard by the patient only, and not by the observer, and the explanations of their existence have occupied a considerable amount of attention. The sounds are often located in some region of the head (tinnitus capitis) and not in the ears, and it is with the possible intracranial origin of such sounds that I propose to confine my attention.

With regard to tinnitus so frequently associated with some disease in the ear I have but little to say. The noises caused by some foreign body, such as cerumen, in the meatus, by some affection or obstruction in the Eustachian tube, or by some nasal or naso-pharyngeal obstruction, by affections of the tympanic membrane, and such conditions as oto-sclerosis, chronic suppuration of the middle ear, and diseases affecting the labyrinth, are all outside present consideration. It is fully recognised that tinnitus may be caused by various changes in the vascular supply to the brain and auditory apparatus, as exemplified in conditions of syncope, hæmorrhage, heat apoplexy, anæmia, arterio-sclerosis, gastro-intestinal disturbances due to reflex irritation of the vagus, toxæmia, uræmia, alcohol, quinine, tobacco, and other drugs, also to anæsthetics, such as ether, chloroform, &c.[1] Wylie refers to other causes of tinnitus, such as variations in the quantity, quality, and pressure of the blood, either in the ear itself or in the brain, such as are induced in adults by worry, excitement, fatigue, debility, indigestion, pregnancy, and menstruation. Tinnitus is also present in cases of vertigo, diseases of the middle ear, the inner ear and labyrinth, or in cerebral disease, or it may be due to reflex irritation from gastric, hepatic, or urinary disorder, or to drugs.

The characters of these noises, described as ringing, whistling, hissing, cracking, pulsating, soft blowing, continuous or intermittent, monotonic or polytonic, have all been fully recognised, adequately differentiated, and explained when associated with disease of the auditory apparatus; but when, on the other hand, they appear to be of intracranial origin their recognition, objective appreciation, and explanation have not been by any means so satisfactory. The various signs and symptoms of tinnitus associated with disorders of the middle and inner ear, whether caused by affections of parts supplied by the vertebral, basilar, or carotid arteries, or by some venous congestion caused by the pressure of growths, or goitre, on the jugular veins, or by any cardiac diseases, are also of importance, but outside present consideration.

In 1868 Dr. James Jago[2] gave an account of certain acoustic phenomena which had their seat of origin elsewhere than in the ear itself, and he devoted a considerable amount of attention to the consideration of the means whereby sonorous vibrations were able to traverse the different structures of the head. He pointed out that vibrations were conducted best in compact structures, such as bone and cartilage, and but little through such soft substances as muscle, brain, connective tissue, fat, and skin.

[1] Andrew Wylie: Proceedings of the Chelsea Clinical Society, vol. i., p. 52.

[2] Jago: British and Foreign Medical and Chirurgical Review, vol. xlii., 1868.

The frame receives vibrations from an external body best where it is naked, next best where it is most thinly clad (as at the cartilaginous or bony part of the meatus), and, least of all, wherever there intervenes a watery skin instead of a dry one. In this way is to be explained the fact that sounds having their origin within the brain are not conducted (in health) through the watery medium of the subdural and other intracranial lymph cisterns to the dense bony structures of the skull itself.

NATURE OF THE PROBLEM.

The problem now before us is concerned, not only with the origin and propagation of intracranial sounds to the auditory organs, but also with the effort to explain why sounds—which must necessarily occur in structures such as the brain or wherever there is movement—do not invariably become appreciable subjectively—i.e., what is the nature of the protective mechanism which prevents our subjective perception of actual intracranial movements? With regard to the means whereby sound vibrations are conducted from the bony structures to the auditory apparatus, and the various affections which may impair or intensify that conduction, I shall say but very little, my object being merely to bring before you some facts and theories pertaining to intracranial physics and pathology which may in part serve to explain the origin of some of the entacoustical phenomena which may be appreciable not only subjectively by the patient as tinnitus, but also objectively by the observer as intracranial murmurs. Jago stated that he was not aware that anyone had pretended to have auscultated a tinnitus aurium, and he believed that auscultators have been deceived by accompanying noises. Later he conceded that there might be intracranial noises which ought to be distinguished from pulsatory noises emanating from alterations in the calibre of arteries or veins about the region of the ear, and he quotes Hinton with reference to the beating character, synchronous with the pulse, of certain murmurs sometimes due to aneurysm of the basilar artery.

Sir William Dalby has mentioned a case of tinnitus of so distressing a character that life was rendered perfectly wretched. All the best surgeons in Germany had been consulted without benefit. According to a request made in this patient's will, that his ears should be examined after death, a most careful dissection was made of the temporal bones. No abnormal appearance of any kind was detected. "In the face of this," says Sir William Dalby, "we certainly are not in a position to give a satisfactory explanation of this symptom except in a certain number of cases. For the rest we must be content at present to admit our ignorance of the cause, consoling ourselves with the reflection that the confession of ignorance is the first step to knowledge." There are probably but few of us who have not experienced a similar sense of failure. Dr. Thomas Barr,[3] speaking of tinnitus aurium of intracranial origin as being not only frequent but also a subject for which otologists eagerly and earnestly desired further knowledge, states that a monument truly awaits the man who finds an effective remedy, surgical or medical, for the hitherto incurable forms of this malady. I, for my part, have long sought explanations of some of the auditory phenomena in the insane. The pathological conditions underlying some of their abnormal conditions of auditory perception must of necessity require many years of patient labour and observation. It may be that in some instances, and especially in cases where the sheath of the auditory nerve is affected by an increase of pressure in the lymphatic fluid, direct stimulation of the nerve may cause subjective phenomena somewhat similar to those occurring in connexion with the visual sense when the specific energy of the visual apparatus or tracts is irritated and manifested by symptoms ranging from scintillating scotomata to mere sparks of light or pressure phosphenes. I believe that such direct stimulation is rare except in cases in which degeneration of the auditory nerve is taking place. Another point to be noted is that, although pulsatile tinnitus is common, rarely do we have evidence of similar pulsatile phenomena in connexion with any other of the cranial nerves which, in all probability, would be subject to somewhat identical conditions of influence.[4]

[3] Thomas Barr, M.D.: "Treatment of Tinnitus Aurium," Brit. Med. Jour., vol. ii., p. 1130, 1909.

[4] Gowers states that intermittent sounds may be of central origin, and he has recorded a case of epilepsy in which part of the aura was an intermittent hissing, evidently synchronous with the pulse, and succeeded by two bright lights which seemed to approach the patient by jerks of the same rhythm as the preceding sounds.

With regard to the subjective localisation of sounds, it must be noted that in some instances the power to distinguish between entotical sounds and those of external origin is impaired or even entirely lost. In the insane, for instance, sounds of entotical or intracranial origin may be located externally, in accordance with the law of the eccentric projection of sensations. Sometimes, however, they may be located within the cranium, and when they are hallucinatory they may be capable of a psychological explanation, either as purely auditory, or as revivals of articulatory images. We have, therefore, various sources of error in the subjective localisation of sounds, and a full account of the phenomena of intracranial murmurs requires full consideration of factors which are either exoneural, entotical, esoneural, or psychical. For present purposes, however, we must exclude all exoneural and psychical considerations and deal only with such conditions as are esoneural and as are in more or less direct relationship to the entotical data which have been already so elaborately studied by otologists.

COMPARATIVE ANATOMY OF CEREBRAL LYMPHATIC SYSTEM.

The original form of the auditory organ is a vesicle derived from the epiblast. In the embryo the vesicle becomes separated from the epiblast and becomes connected with the auditory nerve which grows towards it from the brain. It then sinks deeper into the mesoblastic tissue of the skull and becomes divided into the utriculus, from which the semicircular canals become differentiated, and the sacculus, from which the recessus vestibuli and the cochlea are formed. This whole apparatus constitutes the membranous auditory organ or membranous labyrinth. Later, the surrounding mesoblastic tissue becomes chondrified and also ossified to form the bony labyrinth with a cavity (cavum perilymphaticum) filled with perilymph between them. The cavity within the membranous labyrinth (cavum endolymphaticum) contains the fluid endolymph. In fishes the ear lies close under the roof of the skull, and is thus easily accessible to the waves of sound. As we pass higher in the vertebrate series the auditory organs sink deeper in the skull. The comparative anatomy of the ductus perilymphaticus which (from the reptiles onwards comes into connexion with the epicerebral lymph-sinuses serves as a communication between the perilymphatic cavity and the peripheral lymphatic system of the head) is of great interest, and the internal relationships of the perilymph to the endolymph are suggestive of some explanation of the ability of fishes to resist great increase of external pressure, and of birds by means of their air sinuses to resist great diminution of pressure. The main point for present purposes rests in the fact that pressure variations affecting the perilymph may either directly or indirectly affect the endolymph.[5]

At a very early stage of development swellings of the anterior, middle, and posterior cerebral vesicles can be seen. Their cavities, or ventricles, are in direct connexion with the central canal of the spinal cord. The walls of these cavities become more and more thickened, so that the cavities themselves become gradually more constricted. In the lower vertebrates the brain by no means fills the cranial cavity, but in the higher vertebrates the subdural lymph spaces gradually become less in proportion to the other cranial contents. The significance of this will be seen when we discuss the movements of the lymph fluid in relationship to intracranial murmurs.

PHYSIOLOGY OF THE INTRACRANIAL CIRCULATION.

Consideration of the details of the arterial circulation within the cranium need not detain us. Much discussion has arisen in connexion with the manner in which the various anastomoses occur, and elaborate explanations have been given as to the methods whereby local demands for an increased supply of blood may be determined.

In the brain mass the venous system is, like the arterial,

[5] The endolymphatic duct at its upper end perforates the inner wall of the cartilaginous or bony auditory capsule, passes into the cranial cavity, and ends in an expansion (Saccus endolymphaticus) in the dura mater; osmosis can thus occur between the lymph contained in the endolymphatic and epicerebral-lymph spaces respectively. Wiedersheim, "Comparative Anatomy of Vertebrates," p. 205, gives the relationships of the lymph systems as follows: "In Elasmobranchs, the ductus endolymphaticus opens on the posterior part of the roof of the skull, and is thus in free communication with the sea-water. In many reptiles its free end comes to lie close under the roof of the skull beneath the parieto-occipital suture, and in the Ascalabota the duct even leaves the cranial capsule, passes back between the muscles of the neck, and in the region of the pectoral arch becomes swollen to form a large folded sac, from which finger-shaped processes extend right to the ventral surface of the vertebral column and to the submucous tissue of the pharynx. These processes may also branch out in a labyrinthic manner into the orbit, and they are always filled with a white semi-solid mass of otolithic substance, consisting of very minute crystals of carbonate of lime; otolithic matter is also present in the ductus endolymphaticus of all vertebrates, at any rate in the embryo." "In Amphibians, and also in certain Teleosteans, the duct of either side, by means of large sac-like enlargements, may come to lie close to its fellow, either on the dorsal surface only, or on both dorsal and ventral sides of the brain. The latter is the case in Anura for instance. In birds and mammals the ductus endolymphaticus never passes out of the cranial cavity, and in its general relations corresponds with the tube-like ground form described above.

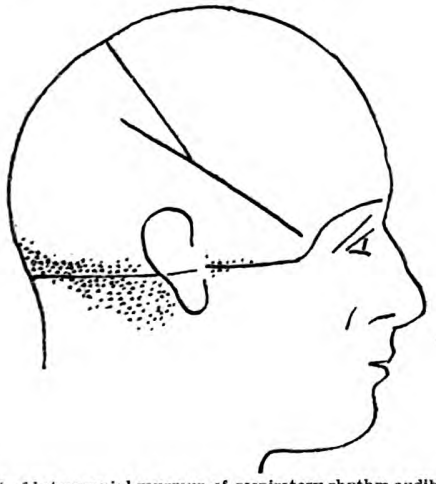
practically capillary, and only on reaching the pia mater do the vessels so coalesce as to form veins of appreciable size. The capacity of the veins within the skull is, as a rule, greater than that of the arteries. The veins, instead of all converging to form trunks differing only in bulk from one another, are emptied into the dural sinuses which cannot, under any circumstances, become appreciably altered in size—i.e., the sinuses can neither collapse from pressure from without nor yield to distending forces from within. The veins from the pia mater open obliquely into the great longitudinal sinus in a direction opposite to the current of the blood. These facts seem to indicate a design whereby the venous outflow is regulated so as to prevent its becoming unduly slow or rapid. The absence of valves in the intracranial veins would, in a measure, prevent the occurrence of any venous murmurs such as are sometimes heard in connexion with the bulbous dilation of the jugular vein, and as in the crural vein in the groin. The exact functions of the trabeculæ found in some of the intracranial veins is uncertain. Possibly they serve not only to regulate the flow of venous blood, but also to prevent the conduction of sound vibrations which might occur in connexion with the flow of blood from vessels of smaller into those of greater calibre. It is assumed that the flow of blood in the venous sinuses of the brain is continuous—without any possibility of pulsatile waves. We know, however, that when the capillaries are greatly dilated, and when the arterial blood pressure is high, the pulse-wave may be propagated through the capillaries into the beginnings of the veins. In the brain, enclosed as it is within an immoveable structure, the only sources of outflow are by the inelastic venous sinuses and by the cerebro-spinal lymph channels. It is readily conceivable, therefore, that any increase of pulsation in the brain itself may communicate pulsations to not only the cerebro-spinal fluid, but also, by direct pressure on the elastic and collapsible intracranial veins of the inner membranes, to the larger venous sinuses. The extra vascular pressure thus causes extra venous pressure, and it is not improbable that a venous sound so generated in the torcular may be propagated in the direction of the venous flow, or even through the denser structures of the cranial bones. Coming now to the other contents of the cranium, it is necessary to speak of the relationships of the cerebro-spinal fluid. The cranium being an immoveable and rigid box does not allow of expansion or contraction either in consequence of pressure from within or without. We can neither add to, nor subtract from, the sum-total of its contents. The brain substance and the cerebro-spinal fluid are in themselves passive, the latter being compensatory to the expansion or collapse of the former, and both reacting to variations in the arterial or venous pressure.

The term "cerebral pressure" really means, therefore, either undue preponderance of one or other of the cranial contents, partial displacement of one or other constituent, acceleration of the arterial or retarding of the venous circulation, or alteration in the compensatory movements of the cerebro-spinal fluid. Arterial, venous, lymphatic, and other forms of pressure due to injury or disease, &c., are but terms used to signify alterations either in the position or in the relative quantities of the cranial contents. The intracranial contents being in the sum incapable of expansion or contraction, it is of importance to note the mechanism whereby the "give and take" between them is affected. The brain itself is inelastic and passive, and depends upon arterial, venous, respiratory, and peristaltic movements for its metabolism and activities. Its substance may be displaced, contracted, expanded, or destroyed by injury, disease, new growths, or finer interstitial degenerative changes. The arterial system may preponderate unduly in its activities, the relative amount of arterial blood being greater than in health. This is due either to excess of propelling action in the arterial system or defect in resistance of the venous or lymphatic systems. The arterial blood may be diminished, on the other hand, owing to defect in the propelling mechanism or to increase in the resistance offered by the venous or lymphatic systems. Similarly, the arterial and venous systems may be concurrently hyperactive or deficient owing to diminution or excess of the constituents of the lymph cisterns. Perfect balance of the relative quantities of the cranial contents thus presupposes certain activities or movements, which are also essential to proper metabolism. The skull thus regulates the pressure of the fluid within its cavity, and any functional increase in the arterial blood would be possible only upon one of two conditions—viz., a corresponding collateral arterial diminution, or a transfer of venous blood in the direction of the venous sinuses. A venous transfer would be altogether too slow, and there could not be any continuous action, for the repulsion of the venous current—dependent upon the respiratory movements—would give rise to a frequently interrupted flow of venous blood in the brain. The cranial cavity is not, however, entirely filled by the brain; it includes, in addition, a number of spaces filled with lymphatic fluid. The dura mater is separated from the arachnoid by a comparatively small space which is lined by endothelium. This space communicates with the lymphatic glands of the neck, and with the subdural spaces which do not immediately surround the nerve-roots, but do so in common with the arachnoid and are connected with the lymphatic spaces of peripheral nerves. As an example, we have the communication between the auditory labyrinth and the subdural space through the spaces which surround the auditory nerves. In the tissue of the dura itself there are also lymph spaces which are connected with the subdural space. The lymph cisterns are traversed by a network of threads and trabeculæ of connective tissue, the threads being narrower at the summits of the convolutions than over the sulci, whilst at the base of the brain where the subarachnoidal spaces are dilated there may be none. It is impossible here to give any account of the anatomy of these lymph cisterns; instead, it must suffice for present purposes to note that they act, not only as water cushions to minimise shocks to the brain and to compensate varying conditions in the blood pressure, but their fluid contents may also serve to prevent the conduction of intracranial sounds to the internal table of the skull. This, of course, refers to normal conditions of the lymph cisterns and their contents, and does not include abnormal conditions in which they may not only fail as non-conductors of sound but in their nature and contents may even be the source of origin and means of propagation of various sonorous vibrations, which may be heard both subjectively and objectively.

Before entering upon a description of the various brain movements it would, perhaps, be well to consider briefly some points in regard to the Pacchionian granulations which occur in the course of all sinuses, and more particularly alongside of the sinus longitudinalis. The cerebro-spinal fluid is removed from the subarachnoidal space by several channels. Much of it passes into the spinal cord, the remainder passes along the sheaths of the cranial nerves, or is excreted by the Pacchionian bodies into the superior longitudinal sinus. The point to recognise is that the fluid from the subarachnoid lymph spaces, when forced from the brain by increased intracranial blood pressure, not only passes into the perilymphatic space of the labyrinth and thereby tends to modify the pressure of the endolymph, but it also serves as a more direct conducting medium for sound vibrations arising in connexion with the pulsatile or other movements of the brain, shortly to be described. The average quantity of cerebro-spinal fluid within the cranium is said to be about two ounces, but the importance of its several functions is but seldom correctly estimated. Its presence not only serves to regulate and make the pressure uniform when brain movements occur, so that every systolic and expiratory dilation of the blood-vessels is concentrated upon those parts where least resistance is offered, but it also acts as the medium for the removal of intracranial waste products.

BRAIN MOVEMENTS.

There are three different kinds of brain movements: (1) Pulsatile movements communicated from the pulsations of the large basal cerebral vessels; (2) respiratory movements, in which the brain rises during expiration and falls during inspiration; and (3) vascular elevations and depressions which alternate and are due to periodic dilatation and contraction of the blood-vessels. This last is a peristaltic arterial movement, regulated by the vaso-motor centre, and occurs from two to six times per minute. Needless to say, it is in connexion with one or other of these movements that sound vibrations are apt to occur in the arterial, venous, or lymphatic systems.



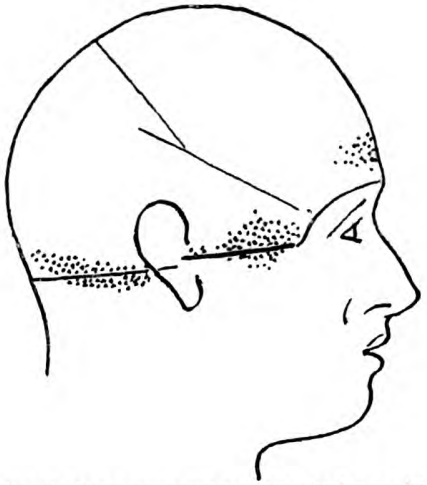
The pulsatory movements of the brain are exceedingly interesting, and undoubtedly they most frequently give rise to intracranial murmurs. From the circle of Willis the

arteries ascend, and their currents are directed upwards in the same direction as the venous currents. The large arteries at the base of the brain communicate a movement to it, each pulse wave raising it up and thereby compressing the cerebral veins. In expiration the venous blood is dammed back into the sinuses, and the brain expands at the expense of the cerebro-spinal fluid. During inspiration the veins are emptied by suction action, the brain collapses, and the cerebro-spinal fluid re-enters the cranial cavity.[6]

During these movements the cerebro-spinal fluid is subjected to doubly compensatory movement—i.e., the pulsatile movement is mainly intracerebral and is concerned mainly with the passage of the fluid through the cerebral tissues and the ventricles, and the respiratory movement which is concerned mainly with the flow of the fluid to and from the cranium. Thus it is that the vascular mechanism of the brain determines not only the intracerebral, arterial, and venous movements, but it also serves to give a peristaltic movement to the ventricles of the brain whereby the cerebro-spinal fluid is slowly passed onwards. This double action may be expressed in another way. The pulsatile action is a factor of causation of the circulation of the blood within the cranium, and it aids in the peristalsis of the intracranial lymph fluid, whereas the respiratory action affects not only the venous flow but also the "give and take" of the cerebro-spinal fluid as a mass in its internal and external relationships.

It seems certain that any excess of cerebro-spinal fluid is always compensatory, and its tension must always be equivalent to that in the veins. For our purpose it is interesting to note that excess of cerebro-spinal fluid within the cranium is not, as a rule, attended by tinnitus. Amongst the numerous cases of cerebral atrophy or sclerosis, with large amounts of compensatory cerebro-spinal fluid, I have met with, tinnitus has been rare. I have, however, seen one case of dementia in which there was an excess of cerebro-spinal fluid and an obstinate intracranial murmur of respiratory rhythm, and located by the patient as being "deep down" in his brain, and distinctly audible on

FIG. 1



Seat of intracranial murmur of respiratory rhythm audible both subjectively and, on auscultation, objectively.

auscultation at both sides of the base of the skull under, and posterior to, the mastoid. Post-mortem examination showed an excess of fluid over the sulci of the convolutions, and chiefly at the base where there were also considerable roughening and large transverse ridges of the inner surface of the bone stretching across the middle cranial fossæ. In this case it seems probable that the tinnitus was due to the to-and-fro movement of the cerebro-spinal fluid over the roughened bone, and its seat of origin in close proximity to the internal ear apparatus rendered it particularly noticeable to the patient. The auditory apparatus appeared to be healthy. (Fig. 1.) It is to be noted that the murmur was of respiratory rhythm and there was no evidence of its having been in any way affected by the pulse wave.

[6] Leonard Hill: Physiology and Pathology of the Cerebral Circulation.

When there is great expansion of the cerebral volume, owing to arterial pressure, and the cerebro-spinal fluid has been driven out of the cranium, the brain comes into contact with the rigid bone, and, as a consequence, any murmur which becomes audible, either subjectively or on auscultation, is nearly always pulsatile, and in the few instances I have seen in which the patients have complained of loud sounds accompanying each pulse wave I have not been able to locate any particular intracranial murmur, nor have I been able to exclude the possibility of their having been subjective so far as I myself was concerned. With regard to the so-called vascular wave, which is due to a peristaltic arterial movement, regulated by the vaso-motor centre, and occurring from two to six times per minute, I have but very few clinical data. These vascular movements constitute an important factor in the nutrition of the brain and in the exchange of metabolic products. The advance of the vascular wave in peristaltic fashion provides a motor mechanism designed to carry off waste products through the lymphatic fluids by establishing currents within the brain fluid. This peristaltic wave action on the cerebro-spinal fluid may determine movements of the fluid over or through structures which may, under pathological conditions, determine sounds with a corresponding rhythm and propagated in the directions of the flow to other ventricles or cisterns. Quite recently I saw a case in which the tinnitus recurred for about three seconds every 20 seconds. It could not be located subjectively, but on careful auscultation I was able to detect a very faint sound recurring at intervals longer than those between the patient's and my own respirations. (Fig. 2.)

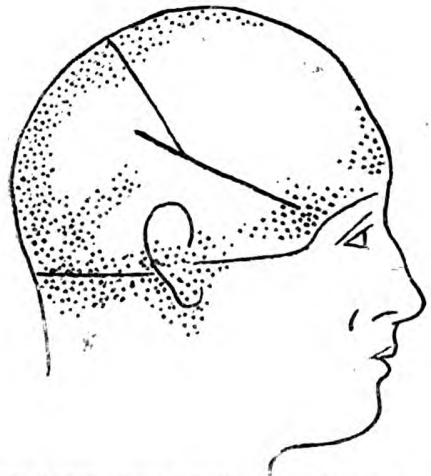
FIG. 2.

Regions at which a murmur of peristaltic rhythm was faintly audible on auscultation.

In this case the sounds were very soft, and they were best heard in the region of the lateral and cavernous sinuses. I fancied I could also detect them just above the superciliary ridges, and at the time it occurred to me that possibly the sounds might be central in origin and propagated through the fluid of the lateral ventricles. This, however, was, of course, mere conjecture. The patient recovered after a course of treatment by digitalis and strychnine.

Anæmia and hyperæmia[7] are powerful agents in modifying pressure equilibrium. The high arterial pressure which occurs in Bright's disease is attended by undue pressure on the peri- and endo-lymph, and gives rise to tinnitus. In hemicrania due to gout the intracranial arteries may be dilated or hyper-extended, and by their more forcible action not only drive the cerebro-spinal fluid from the cranial cavity causing increased tension in the labyrinth, but, by the same process, force the brain towards the internal table of the skull and thereby render it possible for the pulsatile waves to come into almost direct contact with it. So it is in conditions of plethora culminating in apoplexy, of which tinnitus is an early symptom. Tinnitus is often a prominent and distressing symptom in anæmia and chlorosis. It seems possible, however, that the origin of the murmurs is in

[7] Field: "Abnormal Vascular Conditions Affecting the Organ of Hearing," Medical Times and Gazette, 1878, vol. i., p. 616.



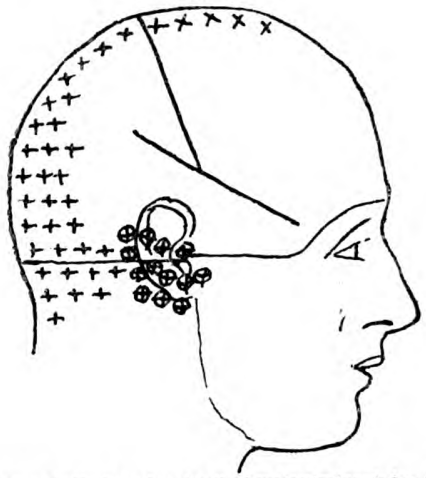
such cases totally different from that of increased arterial pressure. Sometimes the "bruit de diable," either continuous or rhythmical, arising within the bulb of the common jugular vein during diastole and inspiration, is audible both subjectively and objectively. This pathological condition occurs not only in anæmia but also in plumbism, syphilis, scrofula, &c. It is more common in young than in old people, and is due to the vibration of the blood flowing in from the relatively narrow into the wider part of the vein. Similar murmurs have been described as occurring in the subclavian, axillary, thyroid, facial, innominate, and crural veins, and also in the superior vena cava. This can be easily demonstrated by firmly compressing a carotid artery when tinnitus immediately ensues in the corresponding ear.

From certain anatomical and clinical data there appears to be no doubt that intracranial venous murmurs may occur in the same way. The method by which the venous blood from the brain and membranes enters the longitudinal and other great sinuses renders the occurrence of sound-waves not only possible but extremely probable. In health the aspiration of the venous blood from the cranial cavity is probably almost noiseless, but when the aspiration is not supported by a sufficiency of arterial pressure the passage of the venous blood into the sinuses must almost necessarily be attended by murmurs. The exact rôle of the fibrous threads and trabeculæ in connexion with the veins in some localities is not certain. Possibly under certain pathological conditions of impaired activity in the venous outflow there may be with systole and expiration a tendency to regurgitation.

VENOUS MURMURS.

Venous murmurs may be of pulsatile or respiratory rhythm. The blood in the sinuses of the brain may undergo a pulsatile movement owing to the fact that during cardiac diastole much blood flows into the veins (Mosso) and, under some conditions, this movement may be propagated into the veins of the retina and auditory organs. Pulsatile venous murmurs are somewhat difficult to localise subjectively. In young people they are sometimes referred to the region of the lateral sinuses, in climacterics they are more frequent in the region of the longitudinal sinus, whilst, in other instances, especially if they have their origin in the middle line, they cannot be located subjectively. Venous pulsatile murmurs can sometimes be heard on auscultation, and, in the few cases I have auscultated, the murmurs have been confined

FIG. 3.



Regions at which venous pulsatile and respiratory murmurs are located subjectively, and which are sometimes audible on auscultation.

almost entirely to the regions of the larger venous sinuses. In one instance only have I heard a respiratory venous murmur which corresponded with each expiration, and this was evidently due to the aspiration of the venous blood from the lesser into the greater veins. (Fig. 3.)

Frequently patients complain of crackling noises in the region of the longitudinal lateral sinuses and the torcular. (Fig. 4.) Their origin is as yet uncertain, and I have never yet succeeded in auscultating them. When occurring in connexion with the Eustachian tube they may be audible to other persons. Possibly they may be associated with the venous cavernous spaces (fovea glandulares) which, according to Langer and Trollard, are caused by the wearing away of the vitrea, and are to be found in drunkards, in the senile, and in the subjects of heart disease. They are sometimes described as being very loud indeed. Sir William Gowers [8]

FIG. 4.

The crosses indicate regions localised subjectively as being the seats of origin of explosive sounds. The crosses within circles indicate regions at which explosive sounds can be auscultated—probably Eustachian.

refers to the sound produced in an internal aneurysm (of the internal carotid or vertebral) which may be heard by another person on auscultation. Greene [9] mentions the case of a boy who had an intracranial murmur audible on auscultation, and in whom an aneurysm was most unlikely. Poosten [10] also speaks of a case in which a pulsatory sound, resulting from some effect of a blow two weeks before, could be heard eight inches from the patient. It not infrequently happens that insane persons state that all their cerebral and mental troubles began with a loud explosion within the head, as if something had given way. Jago has referred to this phenomenon, and mentions a case in which the explosion seemed to occur near one ear, and ended by a prolonged ringing in the other. He says he has also heard a tinnitus hiss or buzz in one ear as if from a distance, and still later to become appreciable to the other ear.[11]

With the exception of the improbable bursting of an air bubble or cell the explanation appears to be rational. The same observer refers to the fact that the two petrosal and the capacious lateral sinuses are actually supported by the bone that includes the labyrinthian fluid; a sonorous vibration affecting the blood within them may be propagated either through solid bone or in an aural vein to the labyrinth. To account for the transmission of sonorous vibrations across the skull I must again quote Jago, who says: "Should an explosion take place in either of these sinuses its sonorous

[8] Diseases of the Nervous System, vol. ii., second edition, p. 273.
[9] Transactions of the American Otological Society, 1878.
[10] Monatsbl. f. Ohrenheilk., 1878, No. 4.
[11] Jago says: "Such facts indicate that the phenomenon cannot be primarily a nervous affection, for we have no reason for supposing that a sonorous sensation ever passes from one nerve to the other. Nor is it observable that the auditory nerves are exposed to be hit in their paths to the brain by any moving body which assails them separately, and that there should be an actual resonance within the cavity of the skull filled up with brain, or that any bell-like ringing in such a bony cavity, if containing nothing but fluid, could happen, is inconceivable; yet the tinnitus, explosive and transitory, has no resemblance to an arterial souffle, or such a capillary or vascular tinnitus as invades the drum. Nor is it aggravated by closing the meatus, not having sufficient absolute intensity to be conveyed thither in any appreciable degree from its point of origin. To me it seems that anatomy reveals but one apparatus in which the phenomenon could take place, and this one adapted to all its phases. I speak of the chain of large venous tubes and receptacles called sinuses, which connect one petrous bone with the other, and both with other intracranial parts, &c. It surely does no violence to probability to assume that in such a blood current a bubble or cell may occasionally burst, some fibre snap, some collapsed vein leading to a sinus be forced open, or some coherent things part. This being granted, the explanation is palpable."

waves would traverse the Cotunnian fluid on that side immediately, but would have to circulate all round the tentorium to play upon the other side of the head, and would thus be heard later upon the second ear. Such an event might even occur in the beginning part of one of the internal jugular veins, or, may be, one of the cavernous sinuses, and the waves have to ripple over one labyrinth in their course through the lateral sinus, the torcular Herophili, and the remaining lateral sinus, to the seat of the other. If it happens in either lateral sinus there will be a difference in the times of their reaching the two labyrinths, and that difference will be greater as it happens farther from the torcular. Whilst should the starting-point be in the torcular, or any one of the sinuses lying in the mesian plane of the head, the two labyrinths will be attained at the same instant. There may be cases, too, in which the undulations may find their way back again to the petrous bone they have already washed, by being reflected, or by winding their way in a circulating manner through one of the small sinuses that help the lateral ones to keep open a communication between the two sides of the head. Lastly, we may imagine that the sounds under consideration may, in certain cases, be increased by resonance; for example, in such a vessel as the torcular." I agree with him that a chief office fulfilled by the numerous bands which give a spongy structure to the interior of the cavernous sinus is to intercept sonorous vibrations that may be impressed upon its blood current by the internal carotid artery which traverses it, that they may be cut off from the petrosal sinuses.

These observations refer to the conduction of venous sounds. Arterial bruits, if intracranial, are more apt to be central and conducted either direct to the bone in conditions of deficiency of cerebro-spinal fluid, along the course of the arterial stream, or indirectly to the labyrinth through the medium of the venous structures or the lymph cisterns as pulsatile phenomena already referred to.

I have but barely referred to some conditions such as cerebral aneurysm, and there are many other psychological and pathological conditions which may give rise to imaginary or real intracranial murmurs. In fact, this lecture is merely an attempt to reopen a line of investigation which ought, in the long run, to throw some light upon the causes of an affliction which in its far-reaching effects is almost as distressing as any other form of disease from which mankind is prone to suffer. Although our knowledge of many intracranial phenomena is at present scanty and our ignorance of other phenomena profound, it will not always be so, and doubtless we shall, in the course of time, be better able to apply methods of treatment which are based upon a scientific and intelligent appreciation of much that is at present enshrouded in mystery.

THE HUNTERIAN SOCIETY.—Dr. R. Hingston Fox, the President of the Hunterian Society, at a gathering of the fellows and friends of the society on Oct. 6th, delivered an address on the Life and Work of Dr. John Fothergill. In the course of his remarks Dr. Hingston Fox pointed out that after taking his degree in 1736 Fothergill came to London, attending St. Thomas's Hospital, and settled in 1740 in the City, hard by Gracechurch-street Friends' Meeting House. Practice came to him, especially from his kindness to the poor; he used to say, "I climbed on the backs of the poor to the pockets of the rich." His opportunity came in 1748 from an epidemic of septic tonsillitis with a high mortality. He studied the disorder, and worked out a method of treatment, not depleting but supporting, and affording nourishment, air, cleanliness, and cinchona bark. With the Society of Physicians (1752) and the Society of Licentiates (1754) Fothergill was closely connected. In the strife with the American colonies Fothergill's intimate friendship with Franklin and large correspondence enabled him to understand both sides, as did few Englishmen at that time. He pleaded earnestly in the public prints for justice; remember, he said, that these colonists are the sons of freedom; they are become a nation; you can never subdue them. He laboured with Franklin and others to make terms of agreement, but it was not to be. He died in the midst of his work in 1780, at the age of 68 years. The spare alert figure with its keen piercing eyes was active to the last.

INTESTINAL HÆMORRHAGE IN TYPHOID FEVER AND ITS RELATION TO THE AGGLUTINATING POWER OF THE BLOOD.

BY HENRY WHITEHEAD, M.D., D.P.H. MANCH., M.B., B.S. LOND.,

ASSISTANT MEDICAL OFFICER, MONSALL HOSPITAL, MANCHESTER.

IN a work[1] published at Copenhagen in Danish, Enud Schroeder, in coöperation with Professor Dreyer, describes his investigations and observations on the effect of blood-letting in actively immunised rabbits on the agglutinating power of the blood. The immunisation was accomplished by injecting 1 c.c. of sterilised standard culture of typhoid bacillus, paratyphoid bacillus, or bacillus coli communis into the peritoneal cavity. A large quantity (10 litres) of the culture was prepared in order to ensure regularity in the agglutinability of the bacilli, seeing that portions of this standard culture were used in the subsequent agglutination tests. In such tests a macroscopic method was adopted. 4 c.c. of blood were taken from the ear of an immunised rabbit on successive days. The sera having been separated were placed in order of withdrawal into a series of sterilised tubes (11 × 70 mm.) made of glass and arranged on a stand. The quantity of serum put in each tube was varied according to the dilution required. 0·85 per cent. NaCl was used as a diluent, and this along with the sera was added to 1·5 c.c. culture, to make a total of 2·5 c.c. in each tube. A standard tube was taken and the dilution so adjusted that the deposit was just seen by the naked eye. By comparing the tube contents and noting the dilutions, the agglutinating power of the sera of successive days was found, and the fluctuations recorded in the form of a curve.

Schroeder found that after immunisation the blood serum of a rabbit exhibited an agglutinating power which varied slightly from day to day; in other words, a natural curve of agglutination was produced on recording results graphically. By means of a large number of similar observations he drew up a formula by means of which any particular curve of agglutination could be calculated. In each case the readings were checked by the formula, and the results found to coincide.

Bleeding of the rabbits was usually done during a rapid fall of the curve—i.e., in the third phase (see Chart I.). 25 c.c. of blood were drawn off 24 hours after the maximum rise of immunisation was reached. It was known by the formula what the curve would have been independent of bleeding, and thus the effect of the loss of blood could be observed. For the first couple of days after this the curve continued to fall, but not to the same extent as the calculated value; thus there was some checking of the loss of agglutinins. After this there was a sharp rise in the curve, reaching a maximum, and then a gradual fall. During the fall 25 c.c. of blood were again removed, and in 24 hours another sharp rise was noted, followed by a more gradual fall. On repeated bleedings the period elapsing between loss of blood and rise of curve was less, and the subsequent fall more gradual.

Schroeder then describes the effect of bleeding during the rise of the curve. 25 c.c. of blood were withdrawn on the seventh day after immunisation. The rise continued for two days and the fall commenced. The curves were not as regular as the previous ones. The conclusions he draws from his observations are as follows: (1) Blood-letting in the fall is most frequently followed by a further fall, and afterwards by a rise which is often very considerable; (2) repeated blood-lettings each produce similar oscillations; (3) after each blood-letting there is a considerable reproduction of agglutinins; and (4) bleeding in the second phase (i.e., sharp rise) does not apparently affect the rise, which is continued immediately after and with little interruption.

Similar investigations were continued on persons suffering from typhoid fever. Rises and falls in the agglutinating power of the blood were found to occur, as in immunised rabbits. Then bleeding typhoid patients was tried. 150 to 200 c.c. of blood were removed at a time, and the results

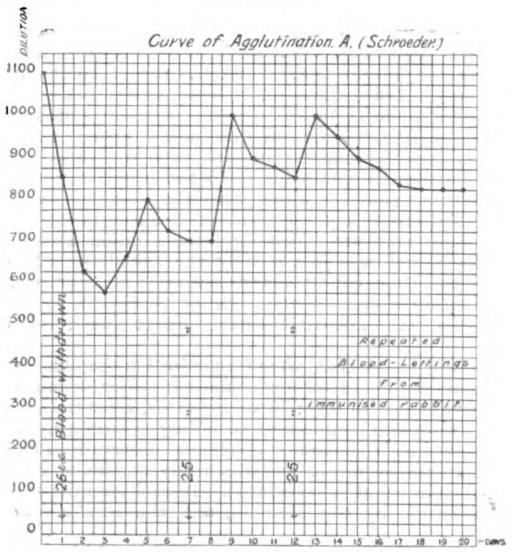
[1] Enud Schroeder: Om Aareladningens Indflydelse paa Blodets Agglutinin-Holdighed. Kbh., 1909.

were very similar to those arrived at in the experiments on rabbits (see Chart II.).

Several observers have attempted to discover the effect of intestinal hæmorrhage in typhoid fever, but apparently without success. No doubt the reason of this was that so few cases under observation happened to have hæmorrhage. Courmont[2] describes five cases; they all, unfortunately, died before any reaction could be found. Jorgensens[3] describes a case of this kind giving a marked rise in the curve during the height of the fever, and he therefore attributes it to the effect of the hæmorrhage on the agglutinating power of the blood. Another case is noted by Fraenkel u Otto and by Lentz and Leube.

Schroeder remarks that it is probable that intestinal hæmorrhage in typhoid increases the power of agglutination of the blood; and whilst it may have a favourable influence on the progress of recovery of the patient, at the same time it must be borne in mind that such hæmorrhage may be very considerable and often fatal.

CHART 1.



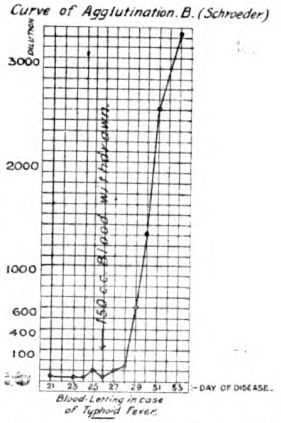


CHART 2.

The above work suggested a new and more extensive investigation of the effect of intestinal hæmorrhage in the human subject suffering from typhoid fever. Such hæmorrhage is undoubtedly a sign that the disease is in an advanced stage, and, moreover, that it is of a serious type. The bleeding is, of course, due to the position of the ulcers with regard to the larger arteries supplying the intestinal wall. Vessels are eroded and hæmorrhage is produced. The great dangers of this accident are (1) perforation of the bowel, almost always fatal; and (2) loss of a quantity of blood too great for the patient to withstand in this weak condition.

[2] La Courbe Agglutinante chez les Typhiques. Revue de Médecine, p. 745, 1897; p. 317, 1900.

[3] Svingninger i Blodets Agglutinerende. Evne ved Febris typhoidea, Kbh. 1904.

Whilst bleeding is recognised as a grave sign in many cases, it must be admitted on referring to these investigations that a great effort is made by the organism to balance this danger. The agglutinating power of the blood is increased after hæmorrhage to a remarkable degree, thus giving the body a much better chance of coping with the advancing disease. What appears to be a bad sign, then, may often prove to be a good one, and may turn the scale and save the life of the patient. Some of the cases graphically described by curves show very strikingly the truth of this statement. 24 hours after bleeding, the curve of agglutination is well up and the temperature down, with the commencement of recovery of the patient. As mentioned above, Schroeder describes a series of cases in which typhoid patients were bled at intervals to the extent of 200 c.c. each time. Almost without exception he finds a fall in the curve of agglutination for the first 48 hours after the blood-letting, and then a sharp rise, due to the effect of the hæmorrhage on the formation of agglutinins. In the present investigations such a fall preceding the rise has not been found. Blood was taken to be tested 24 hours after the hæmorrhage, and without exception showed great increase in agglutinating power. This apparent difference may be due to the fact that very often bleeding takes place in the intestine, and the blood is retained for a day or a couple of days, and so is not noticed at the time it occurs. As a control several cases of hæmorrhage in patients other than typhoid were observed. In none did the blood give any agglutinating reaction at all, either to typhoid bacilli, paratyphoid bacilli, or B. coli communis.

The quantity of blood lost does not appear to bear any proportion to the quantity of agglutinins formed in the blood. A comparatively small amount, say 5 or 6 oz., gives rise to a large increase in the agglutinating power of the blood. In most cases a blood count and an estimation of the percentage of hæmoglobin were done before and after hæmorrhage, but no change other than that observed in ordinary hæmorrhage was found.

The results obtained in the 14 cases to be described prove beyond doubt that hæmorrhage in typhoid fever produces by some means or other an increased formation of agglutinins. Especially is this phenomenon made clear in cases where the day before hæmorrhage occurs samples of the blood serum will not clump either typhoid bacilli, paratyphoid bacilli, or B. coli communis, and yet 24 hours after the hæmorrhage clumping by blood serum taken now in the same dilution (i.e., 1 in 10) takes place immediately. And, moreover, the serum will stand well diluting before it fails to produce agglutination.

The death-rate in cases of typhoid fever where intestinal hæmorrhage has occurred has been worked out by several observers. It was found to be very high in most cases. Of the amount of hæmorrhage no classification was made, nor was any allowance given for the cause or time of death. It is advisable in making statistics of this kind to divide the cases into, say, two divisions, the one group being cases where the bleeding amounted to 10 oz. and under, and the other group cases of over 10 oz. Those in which death ensued within twenty-four hours after loss of blood may with justice be excluded; and deaths from such an accident as perforation of the gut should not be included in the death-rate.

The following figures give the number of cases of intestinal

TABLE I.—*Cases of Intestinal Hæmorrhage in Monsall Fever Hospital, Manchester.*

Year.	10 oz. and under.		Over 10 oz.*	
	Cases.	Deaths.	Cases.	Deaths.
1906	10	2	14	9
1907	11	2	5	1
1908	14	1	9	5
1909	23	6	10	7
1910	24	5	4	2
Total	82	16	42	24
Percentage of deaths	19·5		57·1	

* The average loss of blood per patient was 41 oz.

hæmorrhage in typhoid and the number of deaths which have occurred at Monsall Fever Hospital, Manchester, during the last five years 1906–1910, uncorrected as regards cause and time of death. The division into two parts, however, has been adopted.

Even after this simple division of the quantities, a death-rate of 19·5 per cent. is by no means a high one when it is taken into account that all such cases must be severe ones. And the figure 57·1 per cent. is not great considering that the average loss of blood per case was 41 oz.

This table should be compared with the figures to follow, which represent the total number of typhoid cases in the hospital in years 1906–1910 with the percentage of deaths.

TABLE II.—*Total Number of Typhoid Cases in Monsall Fever Hospital, 1906–10.*

Year.	Cases.	Percentage of deaths.
1906	243	18·1
1907	146	10·2
1908	201	16·8
1909	236	16·9
1910	237	16·3

Average percentage of deaths = 15·6.

The following figures no doubt give a truer idea of the death-rate in hæmorrhage cases.

Of a total of 16 deaths in the first part of Table I. (10 oz. and under) 8 were due to perforation of the intestine. If these 8 cases are eliminated there now remain 8 deaths in 74 cases, giving a percentage of 10·8, which is extremely low. In the other part of the same table (over 10 oz.) 14 of the 24 patients died within 24 hours, thereby not allowing time for the increased formation of agglutinins to take effect. This leaves 10 fatal cases out of 28, giving a percentage of 35·7.

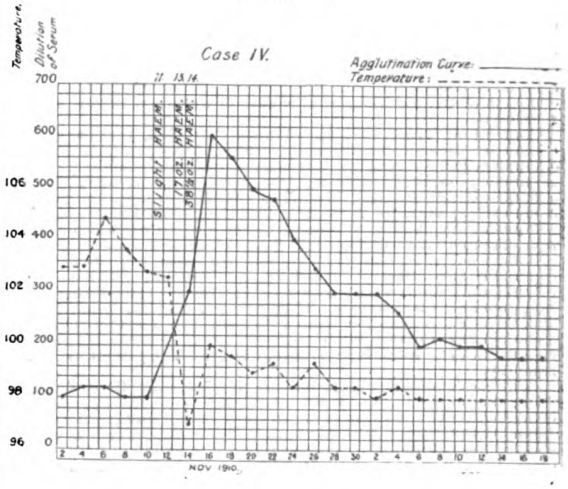
These statistics worked out for the past five years, and thus dealing with a large number of cases, must represent fairly accurately the true state of affairs, and it may be taken for granted that loss of blood in typhoid fever, especially in quantities of 10 ounces and under, is beneficial, and the good done more often than not outweighs the severity of the disease on the other side of the balance.

Nothnagel[4] gives the following statistics of hæmorrhage cases. From 20 to 30 per cent. of those attacked die. Greissinger placed the figure at 31·2 per cent., Liebermeister at 38·6 per cent., and Homolle at 43·3 per cent. Curschmann, the author of the volume on Typhoid and Typhus, gives the figure 38·2 per cent. for Leipsic. For Hamburg he gives 20·9 per cent. in 1886, and as low as 11·6 per cent. in 1887. He also states that he himself has observed 50 successive cases where two deaths only occurred. Graves[5] and Trousseau[6] take the view that hæmorrhage is not a serious but rather a favourable occurrence. The latter supports his opinion by quoting a large number of cases.

The present investigations have been carried out for a period of about a year. As large a number of cases as possible have been investigated so as to include the maximum number of cases of intestinal hæmorrhage. The method adopted was as follows. As a rule a sample of blood was taken from the patient's finger soon after admission in a small sterile glass tube, which was immediately sealed. The microscopic method was used, as it proved to be a convenient and reliable one. The serum was separated from the blood by centrifugalisation, and measured out on to a clean slide by means of a small sterilised platinum loop (Delépine's method) according to the proportion required. A 15 hours old broth culture was used for each observation, and quantities measured in loopfuls as before. The dilutions were made with ordinary sterile peptonised broth, and the same means of measuring it adopted. When the required dilution was obtained a loopful of the mixture of serum, culture, and diluent was placed on a sterile cover-slip and examined under the microscope as a hanging drop preparation. Various dilutions were tried in each case until a point was reached such that *no clumping whatever* took place in half-an-hour. These points of *no clumping* with minimum dilution are the ones registered on the affixed charts, of which two only are here reproduced through lack of space. (Charts III. and IV.) The bacilli in the central part of the drop are the ones to observe, as there is always a certain amount of accumulation of bacilli at the edges which must not be taken into account. Each separate dilution is, of course, a fresh experiment on a separate slide. The same strain of typhoid bacilli was used in the observations on the same case, so as to exhibit uniformity in agglutination, and, moreover, the culture on agar from which the broth cultures were made was as near as possible a month old. It should be noted here that newly isolated typhoid bacilli and also those which have been in use for six months or more lose their power of clumping. Samples of blood were examined every other day, and although only 14 cases had hæmorrhage, a large number of cases were under observation the whole time; it is obvious, therefore, that a great amount of work has been done which does not appear in this paper.

It is impossible to tell whether any particular case is likely to have hæmorrhage or not. From the notes made curves of agglutination were drawn and two of them are here given. The cases are briefly described with a few remarks on each. A copy of the temperature chart is included in the two illustrations.

CHART 3.



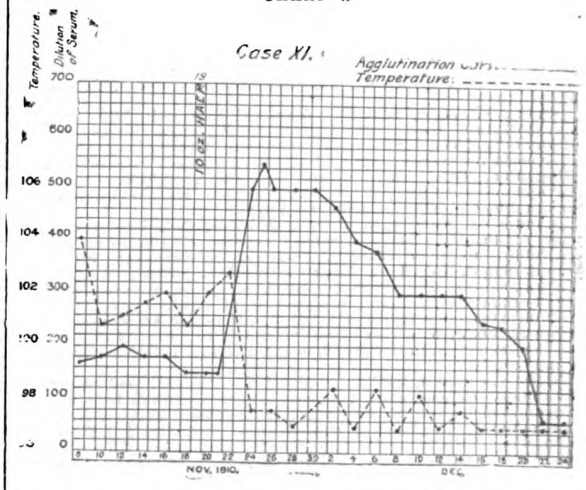


CHART 4.

In conclusion, these cases prove that intestinal hæmorrhage gives rise to an increased formation of agglutinins in the blood lasting for a short time, which may help to tide the patient safely over a dangerous period. As a result of these investigations it is recommended that, in many toxic

[4] Nothnagel's Encyclopædia of Practical Medicine, Typhoid and Typhus Fevers, by Dr. H. Curschmann, p. 224.
[5] Clinical Lectures, 1848, vol. i.
[6] Clinical Medicine, translated by Kunzmann, vol. i, p. 238.

cases of typhoid fever, and more especially in those in which the blood gives a poor agglutination reaction, phlebotomy to the extent of about 10 oz. (according to the physical condition of the patient) be tried as a treatment. It would in all probability give excellent results in many cases, as it would be without the accompanying dangers of intestinal hæmorrhage.

A Few Notes on the Cases of Hæmorrhage investigated.

CASE 1.—A male, aged 20, admitted April 20th, 1910—tenth day of disease. General condition fair; tongue dry and furred; abdomen, no pain, but tenderness on palpation; spleen enlarged; heart-sounds normal; bronchitis present; and a large number of rose spots discernible. Hæmorrhage: April 12th, 6 oz.; 13th, 2 oz.; May 20th, 6 oz.

On May 11th there was a relapse and an accompanying rise of temperature. The temperature was down on May 20th and remained so until the discharge of the patient at the end of June. A good recovery resulted. The curve of agglutination first shows a slight rise and fall before the loss of blood. After this a sharp rise and a very gradual fall, followed by a big sharp rise and again by a more gradual fall. After the second rise the temperature shows a continual fall. Dilution before hæmorrhage, 1 in 250; after hæmorrhage it rose to 1 in 1700.

CASE 2.—A male, age 29, admitted April 16th, 1910—twelfth day of disease. General condition fair; tongue furred; abdomen distended; spleen and liver enlarged; heart-sounds weak; bronchitis and rose spots present. Hæmorrhage: April 23rd, 10 oz. The curve shows a rise and a fall before hæmorrhage, after which comes a big sharp rise, with a fall of the temperature. Dilution before hæmorrhage, 1 in 150; after hæmorrhage, 1 in 550. The patient, who in the early part of the disease was in a very critical condition, made a very good recovery.

CASE 3.—A male, aged 19, admitted April 13th, 1910—fourteenth day of disease. General condition bad, tongue furred; abdomen slightly distended; spleen not enlarged; heart-sounds weak; lungs normal; and a few rose spots to be seen. Hæmorrhage: April 22nd, 8 oz.; 23rd, 30 oz.; 28th and May 1st, slight old hæmorrhage. Here again is seen the sharp rise 24 hours after the loss of blood. In this case there was *absolutely no agglutination* reaction whatever for 10 days before the hæmorrhage, in half an hour, with a dilution of 1 in 10, neither with typhoid bacilli, paratyphoid bacilli, nor B. coli communis. Dilution after hæmorrhage, 1 in 600. The patient's life was in the balance for 10 days before the bleeding, after which he made a slow but very good recovery.

CASE 4.—A female, aged 22, admitted Nov. 2nd, 1910—seventh day of disease. General condition bad; tongue furred and white; abdomen distended, painful, and tender; spleen enlarged; heart-sounds weak; respirations rapid; bronchitis; rose spots. Hæmorrhage: Nov. 11th, a little old hæmorrhage; 13th, 17 oz. old hæmorrhage and 6 oz. fresh hæmorrhage; 14th, 16, 7½, 4, 2, 2, and 1 oz. fresh hæmorrhage. This patient lost about 60 oz. of blood and yet made a good recovery. The temperature remained below 100° F. after hæmorrhage. (See Chart III.)

CASE 5.—A male, aged 21, admitted April 27th, 1910—twenty-fourth day of disease. General condition bad, patient delirious; tongue furred; abdomen normal; spleen not palpable; heart-sounds normal; lungs normal; no rose spots. Hæmorrhage: May 7th, 2 oz.; June 5th, 2 oz. The curve does not show any sharp rises, but there is evidently some reaction to even small losses of blood. Dilution before hæmorrhage, 1 in 150. After hæmorrhage, 1 in 280. The patient made a good recovery.

CASE 6.—A male, aged 34, admitted May 3rd, 1910. General condition poor; tongue dry, brown, and cracked; abdomen normal; spleen much enlarged; heart-sounds normal; lungs normal; numerous rose spots. Hæmorrhage: May 12th, 7 oz.; 15th, 5 oz.; 24th, 2 oz. A very substantial rise is here noted, a further short rise, and then a fall. Dilution before hæmorrhage, 1 in 400; after hæmorrhage, 1 in 1100. The patient was in a very bad condition, but made a good recovery.

CASE 7.—A male, aged 22, admitted May 10th, 1910—sixteenth day of disease. General condition very bad; tongue dry and brown; abdomen distended and tender; spleen not enlarged; heart-sounds weak; pulse dicrotic; bronchitis and rose spots. Hæmorrhage: May 12th, 30 oz., 13th, 25 oz. The patient died on May 13th, evidently from loss of blood. The agglutinin increase was, however, already apparent, and had the anæmia produced by the hæmorrhage been overcome the patient might have recovered. Dilution before hæmorrhage, 1 in 300; after hæmorrhage, 1 in 900.

CASE 8.—A male, aged 39. Admitted July 15th, 1910—twentieth day of disease. General condition very bad; tongue furred; abdomen distended; spleen not enlarged; heart-sounds weak; lungs—bronchitis and rapid respirations; rose spots. Hæmorrhage: July 16th, 12 oz.; 17th, 9 oz.; 18th, 1 oz.; 19th and 20th, slight old hæmorrhage. This patient died from perforation of the intestine. Dilution before hæmorrhage, 1 in 250; after hæmorrhage, 1 in 400.

CASE 9.—A male, aged 27, admitted July 2nd, 1910—seventeenth day of disease. General condition poor; tongue furred; spleen palpable; abdomen normal; heart-sounds weak; no rose spots. Hæmorrhage: July 13th, 14 oz; 14th, 18 oz. This patient died on July 21st, 1910. The reaction occurred as shown by dilutions below, but he did not seem to rally from the loss of blood. On admission and for ten days following this the agglutination reaction was negative to typhoid bacilli, paratyphoid bacilli, and B. coli communis. The loss of blood produced the formation of agglutinins. Dilution after hæmorrhage 1 in 500.

CASE 10.—A male, aged 20, admitted Nov. 15th, 1910—nineteenth day of disease. General condition poor; tongue dry and furred; abdomen, no distension; spleen very large; heart-sounds weak; bronchitis; a large number of rose spots. Hæmorrhage: Nov. 19th, 2 oz.; 27th, 5 oz. and clots; 28th, some old hæmorrhage; 30th, 1 oz. The relation of the curve of agglutination and the temperature curve should here be noted. There is a gradual fall of the latter with the rise of the former. Dilution before hæmorrhage, 1 in 50; after hæmorrhage, 1 in 500. The patient progressed extremely well.

CASE 11.—A male, aged 34, admitted Nov. 6th, 1910—ninth day of disease. General condition poor; tongue dry and furred; abdomen distended; spleen not enlarged; heart-sounds weak; lungs normal; no rose spots. Hæmorrhage: Nov. 21st, 11 oz.; 22nd, clots. Here, again, may be noted the rise of the agglutination curve and the fall in the temperature. The hæmorrhage occurred, as shown, during the natural fall of the agglutinin curve. The patient made a very good recovery. (See Chart IV.)

CASE 12.—A male, aged 51, admitted Dec. 22nd, 1910—twenty-sixth day of disease. General condition poor; tongue dirty; abdomen normal; spleen enlarged; heart-sounds weak; bronchitis; no rose spots. Hæmorrhage: Dec. 28th and 29th, and Jan. 2nd, 3rd, 6th, 7th, and 8th, small clots; 11th, 7 oz.; 14th, 5 oz; 17th, 10 oz.; 18th, 8 oz. The curves speak for themselves and show well the progressive recovery with the rise in the power of agglutination. Dilution before hæmorrhage, 1 in 50; after hæmorrhage, 1 in 650. The patient made a good recovery.

CASE 13.—A male, aged 29, admitted Nov. 17th, 1911—eighth day of disease. General condition fair; tongue clean and moist; abdomen, no distension; spleen easily palpable; heart-sounds normal; lungs normal; no rose spots. Hæmorrhage: Nov. 26th, clots; 25th, 8 oz. There was a big sharp rise after the 8 oz. and then a gradual fall. Dilution before hæmorrhage, 1 in 50; after hæmorrhage, 1 in 540. The temperature commenced to come down after the hæmorrhage. The patient recovered.

CASE 14.—A male, aged 20, admitted Feb. 14th, 1911—fifteenth day of disease. General condition fair, wanders at times; tongue dry; abdomen normal; spleen not enlarged; heart sounds weak; pulse dicrotic; bronchitis; no rose spots; deafness. Hæmorrhage: Feb. 18th, 8 oz.; 19th, 5 oz.; 21st, clots; 23rd, slight hæmorrhage; 24th, 2 oz.; 25th, clots; 26th, slight hæmorrhage. In the chart of this case rises and falls are observed after the first hæmorrhages, on new ones occurring. Dilution before hæmorrhage, 1 in 100; after hæmorrhage, 1 in 650. The patient was in excellent health when discharged.

Manchester.

ACUTE MIDDLE-EAR AND MASTOID INFLAMMATIONS:

THE RELATIONS OF ACTIVE AUTO-INTOXICATIONS.[1]

BY SARGENT F. SNOW, M.D.,

HONORARY PRESIDENT OF THE EIGHTH INTERNATIONAL OTOLOGICAL CONGRESS; CONSULTING OTOLOGIST AND LARYNGOLOGIST TO THE HOSPITAL OF THE GOOD SHEPHERD.

IN the study of a diseased condition we are doubly armed if we have a clear conception of its determining cause. *Knowing* the determining cause and *seeing* easily the local manifestation puts effective weapons in our hands, so that we may attack the trouble from two ways. A double leverage like this is very valuable when we have under treatment acute affections that are liable to develop and extend into vital regions.

Acute middle-ear and mastoid inflammations are well within the list of diseases that call for serious thought, and a suggestion or plan of treatment that will give us increased power over these conditions I am sure will be welcomed by all.

For years specialists have studied and discussed the local manifestations of mastoiditis and their calls for relief, to the end that we now have splendidly developed and effective plans for local treatment. In fact, mastoid operative technique is so perfected by experienced operators that but little concern need be felt for their cases, and perhaps it matters little with these operators whether the etiology of the trouble is considered or not—the patient is quite sure of ultimate recovery from the blood-letting and good drainage they obtain.

The question I would put forward now is whether we cannot modify the danger and cut short the duration of the trouble by working at both the cause and the effect—in other words, working from both ends towards the middle, treating the fundamental cause of the inflammation as vigorously as we treat its results.

Previous to 1909 I was content to treat my acute mastoid cases locally, not giving much attention to the constitutional state, except perhaps a perfunctory order for a cathartic at the beginning of treatment. A closer study of late into the causes of inflammation of the head membranes has given me a different view-point, and I am happy now in the thought that I am much better equipped for a battle against these inflammations.

The whole question of local congestion revolves around, and rests upon, the state of the glandular activities. If the antibodies, nature's army of opsonins, are in normal quantities and in normal activity they fight down and keep under subjection bacteria that are always ready somewhere in our economy for pernicious development. A basic idea in medical philosophy of long ago was that nature provided man with defensive agencies to combat disease. Sir Almroth Wright's development of the opsonic theory and his research

[1] A paper read before the American Otological Society at the Forty-fourth Annual Meeting, Atlantic City, New Jersey, June 26th and 27th, 1911.

showing that the blood serum contains protective substances that act upon pathogenic bacteria add further proof. Metchnikoff has made plain the importance of the protective body cells against micro-parasites. The researches of Ehrlich, Brieger, and others have shown the relations between antigens and antibodies. Hektoen of Chicago[2] locates the probable formation of antibodies as in the spleen and other lymphoid structures, all showing that medical science is rapidly unfolding important truths.

The presence of bacteria *per se* is not sufficient to cause acute inflammations. The soil surrounding them must be favourable to their propagation; the cellular structures must be so modified in functional activity as to be no longer able to keep the pernicious bacteria under subjection.

It is well known that various bacteria may be present in the tympanic cavity without exciting inflammation until the conditions of the secretions and tissues are favourable to their rapid propagation. Those conditions favourable to the rapid propagation of dormant but vicious bacteria are, in my opinion, induced by an active auto-intoxication or crisis of elimination. Membrane congestions, in the author's opinion, with few exceptions, are practically autotoxic expressions; these autotoxic expressions come with more or less periodic regularity, and any organ or sinus covered or lined with a membrane is in danger.

Closer observations on acute pharyngeal, nasal sinus, middle-ear and mastoid inflammations astound me at the invariable relation evident between those inflammations and an active autotoxic state of the system. Frequently we find that there have been weekly evidences that they were self-poisoned—evidences made plain by digestive disturbances or recurring head colds.

Each case may not show all the symptoms of this etiological factor, but the skilled observer will detect some of them. The local signs of auto-intoxication depend largely upon the individual. Sometimes the complexion is perfect, but the eyes or posterior third of the tongue will give the evidences. Not everyone will show a tongue coated to the tip, but he will show some of the other well-marked principal symptoms. By drawing down the lids of the eye his conjunctiva will be found of a yellowish cast, or his skin may be grey or ashen, his breath foul, or his tongue dry and reddened—all proving that the patient's system, from some cause or other, has accumulated a large load of enterotoxins. This load of poisons may be the result of several months of inactivity, constipation, and over-eating. It may be the result of recent dietary excesses, or from overstrain and exhaustion, causing poor action of the liver and digestive functions. Whatever the source, nature demands relief from the stored-up toxins.

Auto-intoxication has a multiplicity of causes, each one leading up to a time when the system can no longer tolerate its load of poisonous substances. The different organs and membranes of the body are forced to do, and will do, double eliminative work until some organ fails or flags in its function; then we have an acute inflammation in some part of the body from the faulty metabolism—an autotoxic crisis. This is the time when the cellular structures are so weak in their functional activity that germs are able to multiply with impunity.

Should the tonsils, accessory sinuses, or tympanic cavities be harbouring staphylococci, streptococci, or any variety of bacteria, these vicious trouble-producers are apt to be soon multiplying at a rapid rate, opposed by only a few weakened attenuated antibodies. The term "attenuated antibodies" is chosen advisedly, because for days, perhaps weeks, the blood secretions and tissues of the patient have been getting so surcharged with poisons absorbed from his own intestinal tract that his army of fighting antibodies, usually capable, have lost their strength in their efforts against his own auto-intoxication. He then becomes a prey to diseases from bacteria originating outside his body, some fulminating, acute, inflammatory process of varying virulency.

It seems to be largely an accident as to where this inflammation shall be located—determined, I assume, by the place in the body where vicious bacteria are most numerous, or causes for local congestion are most prominent. Should the Eustachian tube be closed by an autotoxic cold, should the nasal accessory sinuses be shut off from ventilation and drainage by a congestion of the nose, there is then just the condition proper for rapid development and suppurative processes with attendant consequences. When we see a marked autotoxic appearance in our patients we may expect soon an acute inflammation of some degree in some part of the body. According to Coombe,[3] it seems to depend upon the individual predisposition which organ or part will suffer. He says:—

> In one it will be the nervous system, in another the lungs, in a third the heart, &c. The gradual accumulation of these poisons in the organism will, at variable intervals, determine crises of elimination, according to the nature of the sufferer; at times a febrile access, at others a cutaneous outbreak, or an intestinal discharge; all of which leaves the patient weakened, but otherwise improved for a certain length of time, until a re-accumulation reproduces the same symptoms at necessarily varying intervals.

Let no mistake be made from this paper and the author construed as meaning that, as a rule, local surgical measures are contra-indicated. In fact, in acute mastoiditis surgical measures are indicated in nearly all the cases that reach the ear specialist. It does not follow, though, that the external mastoid operation will have to be performed in all cases showing tenderness and swelling over the mastoid region. Experience has shown that a very large percentage of such cases will recover with the drainage obtained by a free incision of the tympanic membrane, attic folds, and periosteum of the superior canal wall. The kind of operation and the amount of drainage necessary to obtain will depend largely upon the exigencies of the case. Acute middle-ear and mastoid inflammations are clearly of a dangerous, active, fulminating order, and the bacteria present are apt to be of such a virulent nature that constitutional measures alone are not safe to rely upon.

A point that the author would make in this paper is that there are certain alteratives that can cause the blood to become bacteriolytic; certain medicines that seem to act as antigens and induce the formation of more antibodies, or at least rehabilitate them with more antitoxic power. Any substance capable of inciting the formation of antibodies is an antigen. Mercury, iodine, the adrenal extractives, &c., seem to be in this class, and are hopeful adjuncts in the twentieth century fight against disease. Vaccine therapy also holds out some hope, but the indications are not very encouraging in acute mastoid troubles. The author relies at present most upon mercury by the mouth in some form as a remedial agent.

Authorities seem to agree that antitoxic elements are produced in the lymphoid structures of the body, and also that mercury is our most efficient medicinal stimulant of systemic functions. Mercury, then, can very properly be called an antigen, and clinical experiences of my own would seem to prove that it surely has antigenic properties. Properly given, it appears to act as an antigen, stimulating the formation of antibodies to ward off and subdue disease.

As time develops, it is probable that our knowledge as to how to use these alteratives will improve. At present, I find myself prescribing calomel in 1/10 gr. doses, frequently repeated until a grain or a grain and a half have been given. Then after making sure that the bowels are sufficiently active, it is followed by a dose of castor oil or salines. This plan is repeated in two days, and sometimes the very next day if the first has not been satisfactory, and it is continued every second day until active symptoms are subsiding. It is possible that smaller doses, more frequently repeated, would be better for antigenic action. During convalescence, either following the internal or external mastoid operation, I prescribe calomel in good dosage at least every five days, not for its cathartic action alone, but for its double action as an intestinal cleanser, glandular stimulant, and corrective for the whole system.

Since adopting this more vigorous plan of constitutional treatment, and attacking the cause of acute mastoiditis as promptly and thoroughly as I do the effect, I find that recovery is made in at least one-half the time and with one-third the effort, compared with what obtained under my former plan of using practically only local treatment.

CHILDREN'S HOME AT EXETER.—The Exeter board of guardians has submitted for the approval of the Local Government Board plans for the erection of a children's home to accommodate 74 children (30 girls and 44 boys) at an estimated cost of £6500.

THE OPHTHALMO-REACTION OF CALMETTE IN THE EARLY DIAGNOSIS OF PHTHISIS.

BY A. STROUD HOSFORD, M.R.C.S. ENG., L.R.C.P. LOND.,

LATE SENIOR RESIDENT MEDICAL OFFICER TO THE ROYAL HOSPITAL FOR DISEASES OF THE CHEST, CITY-ROAD, LONDON.

WHILE resident medical officer at the Royal Hospital for Diseases of the Chest I had the opportunity of studying the effects of Calmette's reaction on patients exhibiting various stages of pulmonary tuberculosis. I think it may be of some interest to bring these cases before the profession.

The solution of tuberculin which was employed consisted of glycerine-free desiccated tuberculin of strength 0·1 per cent. prepared from Koch's old tuberculin manufactured by Farbwerke vorm Meister Lucius and Brüning. One to two drops of this solution are dropped into one eye of the patient near the inner canthus. In the meanwhile the lower lid is drawn down by means of the finger, which is kept there for a minute or so to ensure absorption; otherwise it is inclined to be squeezed out, as the patient naturally closes his eye. In *all* cases before the drop is inserted the eye should be carefully examined for any sign of disease, old-standing or recent, in order to avoid any risk of serious inflammation. Unless the eye is to all appearances free from disease no tuberculin should be placed in it.

The resulting inflammation differs in different individuals, both in time of onset and in the intensity, irrespective of the amount of the involvement of the lungs. In my experience some cases have shown definite reaction as early as three hours after the application of the test; on the other hand, some patients have not shown any reaction until as late as 36 to 40 hours after the test was applied, but in the majority of cases the maximum reaction is obtained in about 12 hours.

The reaction produced may consist of slight conjunctival injection, of marked injection of the whole conjunctiva, both ocular and palpebral, or of marked injection with a mucopurulent discharge, and the patient experiences the usual symptoms of simple conjunctivitis, which entirely clears up in the course of three or four days. In one case, in which a stronger solution was used (1 per cent.), there was not only a marked conjunctival reaction but also an inflammatory condition of the surrounding tissues closely resembling that produced by erysipelas. As a rule, no treatment is required. If the patient complained much of the irritability of his eye the usual treatment for conjunctivitis was employed, but in my experience this was rarely required.

Some observers have recorded bilateral results; none of our cases have shown this. If Calmette's test has been applied to the eye of a patient with pulmonary tuberculosis and several weeks afterwards Koch's old tuberculin has been injected in the usual manner with a positive result, the same eye in some cases has been relit up by a secondary inflammatory reaction.

In some cases of early involvement of the lung no *physical signs whatsoever were discovered*, and the disease was only suspected on a history of hæmoptysis. These are the cases which I should like to emphasise, and in which Calmette's reaction came to our aid and proved to be of the greatest value, the diagnosis being confirmed later by the appearance of crepitations at one or other apex. Thus a positive reaction may be said to carry great weight, and the patient would be wisely treated from the first as if physical signs had existed. One often sees a patient who complains of "bringing up blood," and in whom *no* physical signs can be found; hence it is difficult to say where the blood is coming from, but, as I have just stated, if Calmette's test is positive, in such a case it throws a grave suspicion on one or other lung.

A negative reaction by no means excludes phthisis, as the test may fail in some early cases, but more especially in old-standing ones, and those who are moribund. If Calmette's test proves negative, and pulmonary tuberculosis is suspected, then a second application has been made in from three to four weeks' time; on this occasion, however, to the other eye. If a reaction now takes place, in my opinion the patient is undoubtedly tubercular, but this was found only to be required in a few cases. I have seen two cases in which a third application was necessary before a positive reaction was obtained. Patients who have had the test applied have been seen some considerable time after, even as late as a year, and I have *never* had a case which showed any bad results whatever.

Summary.—Out of 225 cases in which Calmette's reaction has been tried, 100 were cases of pulmonary tuberculosis, which all reacted with the exception of seven. These seven were undoubted phthisis, the sputum containing tubercle bacilli. Five of these seven were in an advanced condition; two of these five gave a reaction to a subcutaneous injection of Koch's old tuberculin. The remaining two cases were early, and, as I have stated above, their sputum contained tubercle bacilli.

Of the remaining 125 cases which were not phthisis, and so did not give the test, 25 were cardiac cases of all varieties; 31 were simple bronchitis which cleared up; 20 were chronic bronchitis and emphysema; 23 were of various kinds—e.g., gastric ulcer, dyspepsia, enteric fever, empyemata, neuroses; 8 were bronchiectases; 6 were simple pleuritic effusion of pneumococcal origin; and 12 were cases of lobar pneumonia all of which resolved. In all these 125 cases tubercle bacilli, although repeatedly looked for, were found to be absent from the sputum, and also from the six cases of simple pleuritic effusion.

Conclusions.—1. A negative result by no means excluded pulmonary tuberculosis. Some very advanced cases failed to give a reaction. 2. I have *never* obtained a positive result except in true cases. 3. I never saw any bad results whatever from the use of the test as regards the eye. 4. If a patient in a suspicious case fails to give a reaction, then the test should be applied on three different occasions, with an interval between each application of from three to four weeks.

I am greatly indebted to the physicians of the hospital for their permission to publish these results. My thanks are also due to my colleague, Dr. A. J. B. Leckie, the house physician, for his kind assistance in compiling the cases.

Northfield, Birmingham.

RESEARCHES IN EPILEPSY.

BY D. MOORE ALEXANDER, M.D. LIVERP.,

PATHOLOGIST TO THE ROYAL SOUTHERN AND WORKHOUSE HOSPITALS, LIVERPOOL, AND TO THE MAGHULL EPILEPTIC COLONY; ALEXANDER FELLOW, LIVERPOOL UNIVERSITY.

THE following investigations into the pathology of epilepsy were undertaken in connexion with the Maghull Epileptic Colony. They are varied in character and do not pretend to have followed any special scheme of line or study, though the majority of them have originated from an idea that the conditions in the intestinal tract have an influence upon the disease. Several are in the nature of repeat experiments upon the work of previous workers. A few have not been attempted before, as far as can be discovered, in connexion with epilepsy.

The work done falls into several categories, and a classification at the outset may tend to simplify subsequent description.

I. *Brain.* 1. Attempts to produce an epileptic animal. 2. The histology of an epileptic brain.
II. *Blood.* 1. The agglutination reaction of epileptic blood with bacillus coli. 2. The opsonic index of epileptic blood for bacillus coli.
III. *Urine.* 1. The urea-ammonia ratio. 2. The evidences of intestinal putrefaction that are afforded by chemical examination of the urine. 3. Correlation of these evidences with the actual putrefactive organisms present in epileptic fæces.
IV. *Fæces.* 1. A general bacteriological survey of the fæces of eight epileptics. 2. A special bacteriological survey of the fæces of an early case.

I. *Researches on the Brain.*

1. *Attempts to produce an epileptic animal.*—It is a noticeable feature of epileptic brains, always when they are seen during life upon the operating table and generally at a post-mortem examination immediately after death, that they present a markedly œdematous appearance to the eye. Closer examination reveals that the œdema lies under the dura mater, in the arachnoid and pia mater, the immediate coverings of the brain. The fluid lies along the vessels and in the interstices of the arachnoid tissue. When extensive, it forms a single sheet of fluid, more or less divided into little drops and ponds by the

divisions of fine fibrous tissue springing from the arachnoid and pia mater. Neither chemical nor bacteriological examination of this œdema fluid by any known method has afforded the discovery of the reason for its presence in epilepsy. It consists of normal cerebro-spinal fluid, and has all the properties and characters of that fluid. Some observers state that it contains more albuminous matter than is normal, and contend that this points to the fluid being the result of an inflammatory process.

It is possible that the mere presence of this fluid might conduce to a condition of the cortical nerve cells of the brain, which would make them peculiarly sensitive and prone to nerve discharges, or from their hypersensitiveness more exuberant in their reaction to stimuli. It was with a view to decide upon the importance of the mere presence of this fluid that the following experiments were undertaken. First, to produce this œdema experimentally in animals. Secondly, to determine whether this œdema, thus produced, was capable of producing epileptic convulsions.

It was found impossible to produce *permanent* œdema of the membranes by any method of fluid injection, and hence the answer to the second question still remains undecided. Altogether 37 rabbits were trephined, various fluids containing albumin were injected under the membranes in varying amount, and the bone was replaced. Natural albuminous fluids were used in the hope that they would be slowly absorbed, and that the artificial œdema produced would last long enough to produce effects. Blood sera and epileptic cerebro-spinal fluid were employed. Pig's serum saturated with common salt was used in the hope of attracting fluid from the vessels and increasing the œdema. Indol, which has always been looked upon as a convulsant, and which is normally manufactured in the intestinal canal by the bacillus coli, was also injected in a very dilute solution, which also contained albumin. Some observers have remarked that the stools of epileptics contain a toxic body of nature unknown, which has convulsant effects when injected into animals. An extract of epileptic fæces was therefore sterilised and injected into the brain membranes of three rabbits which all died, probably poisoned, but even they showed no convulsive seizures.

Table I. gives the results in tabular form:—

TABLE I.

—	Fluid used for injection.	Died operation.	Died afterwards.	Fits.	Recovered.
18	Pig's serum, 0·5, 1·0, 2·0 c.c.	3	2	0	13
5	Pig's serum saturated with NaCl.	0	2	0	3
3	Epileptic cerebro-spinal fluid.	0	0	0	3
8	Solution of indol in peptone water.	1	1	0	6
3	A sterilised extract of epileptic fæces.	2	1	0	0
37	—	6	6	0	25

It was found that 1 c.c. was the largest amount that could with safety be injected at one time, and with this amount great care had to be taken to carry out the injection very slowly, otherwise the animal died almost at once from cessation of respiration. Of the animals, six in number, which died after the operation, two succumbed to septic meningitis, one from a hæmorrhage into the brain through accidental puncture of a vessel, and three from symptoms of pressure from too large a dose. One rabbit injected with normal pig's serum had a spasm of some sort early next morning, but recovered entirely and showed no more symptoms.

Since these experiments were undertaken, six rabbits have been injected with different fluids to discover if it were possible to project the fluid along the vessels into the spaces in such a way that it might be retained. Ten other rabbits which had died from other causes were trephined post mortem, and attempts made to produce an œdema of the arachnoid and pia mater spaces. All these attempts ended in failure. It was found impossible to inject the fluid in any way that it might be retained.

2. *Histology of the epileptic brain.* (*a*) *Histology of the choroid plexuses.*—With this œdematous condition of the membranes the epileptic brain frequently presents an excess of fluid in the ventricles, which are sometimes distended and distorted out of all shape and size by the liquid they contain. Since this liquid originates in the secretory cells of the choroid plexuses, which lie in the lateral ventricles, it was considered worth while to examine these histologically to discover if any abnormality might be present accounting for this hypersecretion or transudation. In all, the choroid plexuses of seven epileptic brains were removed post mortem and placed in fixing fluid. Sections were made of various portions, which were compared with similar sections made from the choroid plexuses of normal brains. No abnormalities of structures were found.

(*b*) *Histology of the epileptic brain cortex.*—The histology of the cortical cells has been investigated by innumerable observers, and, except in very chronic cases, very little has been remarked. Turner examined the cortex for the purpose of investigating the conditions of the blood-vessels. He was able to discover minute clots in the arterioles, which he considered to be the cause of fits by the irritation of their presence. Nine epileptic brains have been sectionised and various parts of the cortex suitably stained. No clots such as Turner described have been found.

II. *Researches on the Blood.*

1. *The agglutination of B. coli communis.*—The toxic theory of epilepsy is one that has obtained great support in past times, and the favourite origin of the manufacture of the toxin has been placed in the intestinal canal. Very many and very various have been the attempts to discover a specific toxic body in epilepsy, and the minds of the greatest number of observers have been directed towards an investigation of the intestinal contents of epileptic patients. The bacillus coli has fallen under suspicion as the producer of nerve toxins, and it was for this reason that indol, which is formed by the B. coli from albuminous materials, was employed in some of the experiments on rabbits.

In all, the sera of 24 epileptics and six normal individuals were tested against four strains of B. coli communis. One strain came from a healthy stool, two were isolated from epileptics at the Colony, and the last was a laboratory specimen. Dilutions were carried up to 1 in 100, and were made 1 : 5, 1 : 10, 1 : 20, 1 : 25, 1 : 50, and 1 : 100. The first three dilutions were made first, and if any agglutination occurred in the 1 : 20 dilution within two hours the further dilutions were then proceeded with.

In three of the controls some slight agglutination occurred in two hours in the 1 : 20 dilution; in four of the epileptic sera a little more than a tendency to agglutinate was observable in the same period. In none of the 30 sera tested did agglutination take place in higher dilution than 1 : 20 in two hours.

2. *The opsonic index against B. coli.*—Fifteen epileptic sera were examined with the laboratory strain and against one strain of B. coli recovered from an epileptic stool. The control sera, single on one occasion only, plural in all others, were usually formed of a pool of three normal healthy sera. The results of this investigation were quite negative. The indices varied within normal limits, and on the whole the variations amongst the 15 epileptic sera were not so wide as between the individual sera of six healthy persons which were examined against one another.

III. *Researches on the Urine.*

1. *The urea-ammonia ratio* is of little value in itself as evidence of liver activity. It was used in this case, probably mistakenly, to gain some idea of the urea production. Urea is formed in greater part by the re-combination effected by the hepatic cells of ammonia and carbonic oxide, in the form in which it occurs in venous blood (ammonia carbamate). If the liver loses this power to any extent less urea will be manufactured, and ammonia in some form will escape into the blood. Too much ammonia or too little carbonic oxide, either of which conditions might occur through an error in metabolism, would lead to the same result. The alkalinity of the blood would be affected in consequence, though its restoration to normal would take place rapidly by the automatic readjustment of the phosphates. But such an alteration in reaction, though slight and transient, might be capable of affecting sensitive nerve-cells. The gravity of such an altered condition is heightened if the powerful

convulsant effects that ammonia can produce when injected experimentally into the circulation be remembered.

So far only six cases have been examined, but these have been investigated for some months. The 24 hours urine was collected in a covered receptacle containing some thymol to prevent decomposition. The urea was estimated in a Gordon-Little's ureometer. The ammonia determination was performed by three methods, and finally that of Schlössing was adopted as it was the simplest, and if attention were paid to uniformity of the surface-area of urine exposed the error as estimated by the control methods was very small.

It was found that the urea-ammonia ratio varied very much; at times it reached 100 or even more; at its lowest it became as low as ten, in one case 9·3. These numbers were obtained as per following example:—

$$\frac{\text{Amount of urea passed in 24 hours grammes}}{\text{Amount } NH_3 \text{ passed in 24 hours grammes}} = \frac{41{\cdot}77}{1{\cdot}081} = 38$$

The fits appear to have some correspondence with a low ratio, although occasionally there is a fit when a high ratio occurs. For example, the ratio was obtained daily in Case 1; it runs:—

CASE 1.—9·33 (1 fit), 12, 36, 82, 28 (1 fit), 38, 55 (1 fit).
CASE 2.—97 (1 fit), 10 (1 fit), 18, 154, 37 (1 fit), 36, 33, 35.
CASE 3.—134, 45·2, 24, 10 (2 fits), 18 (2 fits), 36, 45 (1 fit), 29 (1 fit).
CASE 4.—17 (1 fit), 48, 30, 28 (1 fit), 83.
CASE 5.—40, 40, 40, 40, 28 (1 fit).

These are weeks taken at random from the charts of daily investigations and speak for themselves. A larger series is required before anything definite may be said.

An attempt was made to obtain the first urine passed after a fit. This was difficult, for the patient so frequently micturated unconsciously. But eight specimens were eventually obtained from different epileptics and passed not more than four hours after the attack. The urea-ammonia ratio of these eight specimens runs: 7·6, 12, 5, 5 7, 3 0, 12, 38, and 15; low in every case.

2. *Evidences of intestinal putrefaction.*—This was investigated by means of Ehrlich's test. A solution of para-amido-benz-aldehyde in hydrochloric acid is added to urine, using 10 c.c. of urine and 1 c.c. of the test solution for uniformity. A deep-red cherry colour indicates putrefaction, and its degree is said to be measured by the depth of colour produced. Herter has found a correspondence between the amount of skatol in the fæces and the intensity of this reaction. The test was performed on each urine in the following way. Ten cubic centimetres of urine were measured into each of three test tubes, and 1 c.c. of the Ehrlich solution added. One tube was placed aside, the second was gently warmed, and the third rapidly raised to boiling-point.

The results were tabulated in four classes, indicating the production of colour in the cold, on gentle heat, on boiling, or only after boiling and standing some time. Twelve control urines of healthy individuals were first investigated. Of these, two only gave a reaction in the cold at once, seven a reaction on gentle heat being applied, and three a slight reaction on or after boiling. Twenty-three epileptic urines were examined. No urine gave an immediate reaction in the cold. Eight gave a reaction in the cold after standing from varying periods from half an hour to two hours; five gave a colour only after gentle heat. Four required to be boiled to obtain the test; the remaining six required to be boiled and allowed to stand for some hours before a definite cherry tinge appeared.

3. *Correlation of urinary and intestinal evidences.*—Many theories of epilepsy accuse the alimentary tract as the source of the disease. There is no doubt that intestinal irritation frequently precipitates an attack, and, on the other hand, that attention to bowel functions and diet has always some effect, and often a pronounced ameliorating influence, upon the number of attacks. The common cause of intestinal irritation proceeds from constipation and its consequences, and is due to the putrefactive products of retained excreta. The products chemically fall into a class of substances of which indol, phenol, and skatol are good examples. The body in protecting itself combines these bodies with sulphur to form sulphates, in which form they are comparatively harmless. Thus indol is converted into indoxyl-sulphate, and can be recognised as indican in the urine with its well-known blue colour. When thus converted the bodies are excreted by way of the urine and can there be estimated. Other sulphates appear normally in the urine, such simple salts as sodium and potassium sulphate. In the normal body the complex sulphates comprise a tenth of the total sulphates excreted.

In Table II. the total number of putrefactive organisms has been estimated in a gramme of fæces, and in another column the ratio of complex to total sulphates in the urine of the 24 hours previous to the motion. The putrefactive organisms are here estimated as B. aerogenes capsulatus, which is the anaerobic inhabitant of the lower intestine capable of attacking proteid material directly.

TABLE II.

Total putrefactive organisms.	Sulphate ratio.	Total putrefactive organisms.	Sulphate ratio.
1. 1000, not 10,000	1 : 5·7	5. 10,000	1 : 15·6
2. 10,000	1 : 10·3	6. 1000	1 : 14·8
3. 100,000	1 : 5·3	7. 10,000	1 : 11·8
4. 10,000	1 : 12·6	8. 1000	1 : 10·3

Herter and Smith have tried to show that fits run parallel with the ethereal sulphates of the urine. According to their investigations, the fit is preceded by a rise in the ratio, and this rise they suggest to be due to intestinal putrefaction. In the table above there seems to be no parallelism between the intestinal contents and the ethereal sulphates.

IV. *Researches on the Fæces.*

1. A complete bacteriological examination has been made in eight cases of epilepsy from Maghull. In each case as many various organisms as possible were isolated and tested upon various media—(1) to identify them; and (2) to examine their cultural and morphological characters. Special attention was paid—(1) to the strains of B. coli isolated; (2) to the numbers of putrefactive organisms present; (3) to the number of staphylococci; (4) to the number of streptococci; and (5) to the number of aerobic spore-bearing organisms.

All results were made comparable by the use of a routine method of dilution of the fæces. In each case a gramme of the stool was carefully weighed out and diluted with 99 c.c. of water, making a dilution of 1 in 100; 10 c.c. of this were transferred to another flask containing a further 90 c.c. of water, making a second dilution of 1 in 1000. This process was carried on until the final dilution was 1 in 100 million. 1 c.c. of this final dilution contained 100 millionth part of a gramme of fæces. 1 c.c. of each dilution was used for inoculating plates of neutral-red-lactose-agar, lactose-litmus-agar, gelatin, often ordinary agar. These were incubated aerobically and anaerobically, and the colonies were counted from day to day. Dilutions were also heated to 80° C. for 20 minutes to kill off all but spore-bearing bacilli, and milk tubes were inoculated from them.

To act as controls some 20 normal fæces have been examined in a similar fashion, so that comparisons might be made. It has been found impossible to adopt any standard of normality for healthy fæces. The variations that take place from day to day in the same individual and from one individual to another swing within wide limits. The only standard that appears to remain fairly fixed is relationship of the classes of organisms one to another.

The epileptic fæces examined have shown no striking points of divergence from the normal. The results of this work have been extremely disappointing, especially after the amount of time and labour that has been put into it.

2. *A special case.*—In May, 1909, a boy, aged 7, was seen, who suffered from *petit mal*. His history was as follows: He had always been a delicate child, and at the age of 3 years contracted a severe attack of gastro-enteritis, profuse diarrhœa with very offensive, slimy, and bloody stools. At this time he had a fit and remained unconscious for 24 hours. The fits recurred after the intestinal condition was relieved up to the age of 5, but they were few and far between. From May, 1907, to June, 1908, he had no fits, but they began again in this latter month. His mother noticed that his motions had become very offensive, and also that he cried out that he had pain in the abdomen before a fit came on.

Treatment with bromide had little effect. Grey powder gave no relief. His motions were examined bacteriologically and the condition was that of great diminution in the colon group of bacilli and a great rise in the putrefactive group. The stools were soft, gaseous, and extremely disagreeable to the nose. They were examined twice, and he was then taken into the Royal Southern Hospital, where he received lactic

acid bacilli in milk. The last two weeks he was in hospital he had no fits, and for a week after returning home he had none. The intestinal condition was entirely changed under the influence of suitable food, attention to the bowels, and the lactic acid bacilli. But the influence upon the fits was practically *nil*.

Conclusions.—It will be noticed that the results of these investigations are uniformly negative with one exception. There appears to be a relationship between the fit and a low urea-ammonia ratio.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

NOTE ON A CASE OF ACUTE ANTRUM OF HIGHMORE WITH EYE COMPLICATIONS.

BY JOHN R. FOSTER, F.R.C.S. EDIN.,
OPHTHALMIC AND AURAL SURGEON, CAMERON HOSPITAL, WEST HARTLEPOOL.

A WORKMAN was sent to me on June 30th of this year with the following history. Fourteen days prior to his visit to me he had a severe attack of influenza. On the day following the beginning of this illness he explained to me that he had very acute pain of a neuralgic character, confined to the left side of his face and head. Two days following the neuralgia he began to notice that the sight of the left eye was becoming dim, also that his sight was double; this latter feature be especially noticed on descending the stairs from his room. I found his condition as follows:—

The patient was a young man 22 years of age. From the position in which he sat, and the distortion of his face, it was evident that he suffered great pain. His left eye had a marked vertical squint, only the lower half of the cornea being visible. The pupil was dilated and sluggish to strong light, and it was under the circumstances difficult to estimate his vision accurately, but it appeared to be about 6/60. When I palpated between the eyeball and the inferior orbital wall there was a distinct swelling, irregular and firm, only slightly painful on pressure; there was also some œdema of the lower lid, which the patient explained was not so bad as it had been on the previous day. The fundus of the eye showed the edges of the optic disc blurred and the vessels distended and tortuous; I could not make out any difference in the level of the disc and the surrounding retina. With red and green glasses well-marked diplopia was shown, both horizontal and vertical in character, the vertical being the more marked.

The diagnosis rested, in my opinion, between tumour of the antrum and acute antrum. I punctured the antrum below the inferior turbinate and syringed out some pus with a very offensive smell. It appeared to me that the best thing under the circumstances was to make a good exploratory opening through the canine fossa. I did this and found nothing in the antrum except a small quantity of pus and some polypoidal mucous membrane. A gauze drain was inserted, and in a few days all symptoms disappeared.

West Hartlepool.

RUPTURE OF AN EMPYEMA INTO THE ŒSOPHAGUS.

BY WILLIAM A. BULLOUGH, M.SC., M.B., CH.B. VICT.

A GIRL, aged 16 months, was admitted to the Royal Albert Edward Infirmary and Dispensary, Wigan, on Feb. 8th, 1911. Her medical attendant had explored the chest and found pus. The child was in an extremely emaciated condition, and cried in a peculiar way that suggested extreme hunger. On exploring the left side of the chest some turbid fluid was withdrawn. A portion of rib was resected, but very little pus was found. The lung was contracted and although a number of adhesions were broken down, did not "come up" well. Next day she continually vomited the milk and other fluids which were got down her throat. At the first dressing it was noted that the discharge resembled curds of milk. Consequently the child was given a little milk to swallow, and thereupon a portion of it came through the wound. The quantity swallowed and the quantity coming through the wound were roughly measured and it was found that about half the milk escaped through the wound. On interrogating the parents it was elicited that the child had been continually vomiting her milk for a week prior to admission. We were of the opinion that it was a case of ruptured diverticulum of the œsophagus. However, the child died next day and we made a post-mortem examination.

Necropsy.—The left lung was contracted and firmly adherent to the posterior pleura. On opening the mediastinum a mass of adhesions was found between the œsophagus and the left pleura. An oval-shaped hole was found on the left side of the œsophagus about 3 inches above the diaphragmatic opening. The hole was three-quarters of an inch long and a quarter of an inch wide, the long axis being in the axis of the œsophagus. The edges of the hole looked as though it had existed for some little time, being nicely rounded off. No diverticulum was found.

The presumption is that an empyema had burst into the œsophagus, that the pus had been expectorated by the œsophagus and mouth, and that the child had died from starvation.

I am indebted to Dr. J. Blair for permission to record this case.

Wigan.

Medical Societies.

ROYAL SOCIETY OF MEDICINE.

OBSTETRICAL AND GYNÆCOLOGICAL SECTION.

Large Fibro-cystic Tumour of the Perineum.—Specimens.

A MEETING of this section was held on Oct. 5th, Dr. AMAND J. M. ROUTH, the President, being in the chair.

Mr. J. D. MALCOLM showed specimens and photographs of a remarkable case in which a tumour measuring 37½ inches in horizontal circumference hung from a woman's buttock to the level of her knees. Her age was 30; she had one child, aged 11 years, and six years before admission to the Samaritan Free Hospital she was under the care of an experienced surgeon who found a lax cyst to the left of the vagina and another behind the uterus. It was thought that there was a double vagina, and an incision was made into the lower swelling, but no pus and very little fluid escaped. A year later another surgeon of large experience found three tumours, one in the abdomen, one protruding from the vagina, and one bulging the buttock. After that time the patient did not consult any medical man from July, 1906, until April, 1911, when the buttock tumour had attained the enormous dimensions above mentioned. The anus was dragged out of place, and the finger, when inserted into the rectum, did not pass upwards into the body but downwards into the external mass, which had an area of resonance on its upper surface corresponding to the position of the lower bowel. There were also a tumour projecting from the vagina and an ill-defined growth in the abdomen. The removal of the new growths was obviously a very formidable procedure, but as there was no hope of relief except by operation the patient was told that the treatment would be very dangerous, and she still was anxious to have it carried out. There was a tumour in front of the peritoneum below the umbilicus, another behind the uterus, a third 7½ in. long projecting from the vagina, and the enormous mass of the buttock tumour. These all united in the anterior part of the pelvis on the left side, and they were removed by combined abdominal and perineal incisions, with the exception of a small part in the pelvis. After much fluid had drained from them the parts removed weighed 39½ pounds. Three of the tumours were soft very œdematous solids; the large buttock growth was partly soft solid and partly cystic. The

solid part of this latter growth seemed to consist of an invasion of the pelvic floor, which was expanded over a mass of large cysts filled but not distended by clear yellowish fluid. The operation was a very severe one and the patient died half an hour after she was put to bed. The remaining part of the growth was removed after death. It had a diameter of not more than 1 inch. It was free from the hollow viscera, but it was firmly fixed to the fascia covering the muscles of the anterior lateral wall of the pelvis. It was easily separated from these muscles, and when it was removed the ascending ramus of the left pubic bone and the obturator vessels and nerve were fully exposed. It was conjectured chiefly from the relations at this part that the tumour developed from fascial tissue. The ureters were dilated to a diameter of half an inch, and the kidneys and their pelves were also enlarged.

In reply, Mr. MALCOLM stated that in the account of the case prepared for printing he had noted the unfortunate fact that this patient had not offered every facility for the consideration of her case to one of the surgeons whom she consulted in 1905 and 1906 or to some other surgeon.

MEDICAL SOCIETY OF LONDON.

The Society and the General Practitioner.

A MEETING of this society was held on Oct. 9th, Dr. J. MITCHELL BRUCE, the President, being in the chair.

Dr. MITCHELL BRUCE, in delivering the presidential address, asked, Was it in the interest of the society that the general practitioner who came to its meetings should be receptive only—should he not be communicative also? At the meetings the general practitioner was furnished with material which he could put to practical tests. Did he return with a report of those trials? The registrar of the society had estimated the proportion of papers presented, and he had found that whilst Fellows of the society in general practice constituted one-third of its members, only 1 communication in 15 came from them—indeed, but four papers had been read before the society by the general practitioner during the last ten years. The President pleaded for a more equal participation in the work of the meetings; he thought that great advantages would be secured to medicine and surgery if a larger share in the work of the society were taken by the family doctor. He was of opinion that not only were certain aspects of disease best studied and best understood by the general practitioner, but that in some of its relations disease could be sufficiently studied and described by him alone, for it was not a question of the individual as a competent observer, but it was a question of his opportunities for observation The President then stated some of the opportunities which, in his opinion, were especially enjoyed by the general practitioner of advancing the science of medicine and surgery.

Dr. LEONARD GUTHRIE read a paper on Recurrent Jaundice with Pyrexia, Splenomegaly, Anæmia, and Pigmentation of the Skin in a girl aged 11 years.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.—At the opening meeting of the thirtieth session of this society on Oct. 6th the in-coming President, Mr. W. McAdam Eccles, was inducted by the out-going President, Dr. Phineas S. Abraham. Mr. Eccles then presented Dr. Abraham with the "Keetley Medal," a medal in bronze founded in memory of the late Mr. C. B. Keetley, one of those who inaugurated the society in 1882. Mr. Eccles then read his presidential address on the Future of Surgery. After reviewing briefly some of the points which indicate the enormous advance that has been made in surgery during the past quarter of a century, Mr. Eccles showed that technical skill in operating was almost useless were it not that Lister had shown the way in which such skill need not be lost by the onset of sepsis. Even now heated debate may occur as to the precise methods for securing asepsis, but the one fact remains that the removal or exclusion from a wound of organisms is the essential to success. This it was that Lister taught the world. No nurse or dresser at the present day was fit to start the rudiments of surgical nursing or surgical practice unless she or he had grasped this fundamental point. Another circumstance which had led to the great advance of surgery, and would of necessity lead even more to its perfecting in the future, was the better training and higher skill of surgical nurses. Surgeons sometimes did not give due credit and praise for the assistance they received from good nurses. Many a case would succumb after the manipulations of the surgeon but for the watchful care of the nurse. Mr. Eccles said he was a strong upholder of a thorough training for nurses, and he believed that State registration must come, and that every nurse worthy of the name would be required to hold a certificate granted after examination subsequent to a three years' course in a hospital of not less than 100 beds with a resident medical officer; the future of surgery—if not of medicine—would demand it. While speaking of nursing, the question of surgical nursing homes or private surgical hospitals naturally came up. In the past these have not been what they might have been. In the future, if maintained for those who were able to afford them, they must improve with the advance of surgery. For the sake of the patient who submitted to the surgery of the future it was best that he should be removed from his home into better surroundings of cleanliness, light, air, and nursing. The ideal surgical nursing home for those who could afford to pay must be thoroughly good—not necessarily extravagant or ornate—furnished with what experience had shown to be desirable for success in operation and after-treatment. It would require to possess properly built and equipped theatres, after-treatment bedrooms, convalescent rooms and verandahs, lifts, bathrooms, an X ray and a pathological department, and sufficient ground around for a well-kept garden, and to be some distance from the centre of the town. This the surgery of the future would demand and have. For the middle-class patient also something better must be done, but he was not fully convinced as to what this should be. In the surgical wards of a large hospital a large proportion of the beds were filled by operation cases, and the surgeon in charge had his time and hands filled by operative work, and his teaching tended to become more and more on those diseases and injuries which required operative interference. Thus the surgeon was apt to neglect non-operative cases and the lessons to be learnt from them. The whole art and practice of surgery, in spite of its etymology, did not consist of operative manipulations, and it would be a serious thing for surgery if in the future its exponents did not remain versed in anatomical, pathological, and even purely medical knowledge. The general practitioner to-day was bound to be acquainted with much more of surgery than in the past, but he should not have his brain, as a student, loaded with the details of intricate operations. The day was approaching when the work and teaching in the out-patient rooms, wards, and theatres of the hospitals with medical schools would have to be revised and modelled on different lines if students were to be taught adequately. A number of conditions were making for increase of, and changes in, surgical practice as it affected the general practitioner. The multiplication of factories, the enormous amount of motor road traffic, and the provisions of the Compensation Act had greatly accentuated the importance of "accidents." The clauses of the National Insurance Bill were sadly wanting in any direct reference to the future of surgery. Operative treatment which would be needed for many thousands of persons was practically ignored. In fact, the Bill seemed to have been thought out on the lines of the medical and surgical practice of the middle of the last century, when potions and pills were the rule of the day. This neglect of the claims of surgery by public men could not do otherwise than lead the public to consider that surgery was of secondary importance. The enlightened general public would ere long demand that their medical attendant should be prepared to give no uncertain advice on surgical matters, and hence the great desirability of thoroughly practical teaching, dogmatic if necessary, but sound in fundamentals. The general practitioner was the medical man who after all was far more worthy of respect and honour than many a physician, surgeon, or specialist, but who perhaps but seldom receives his due meed of praise. It was to his acumen in diagnosis, to his promptness in realising the necessity for surgical interference, and to his ability to recognise when he should act or send for a surgeon, that to a very large extent the welfare of the patient and the future of surgery would

depend.—A vote of thanks to Mr. Eccles for his address was proposed by Mr. F. Swinford Edwards and seconded by Colonel E. M. Wilson, R.A.M.C., and carried with acclamation.

ÆSCULAPIAN SOCIETY.—A meeting of this society was held on Oct. 6th, at which Dr. Leslie Durno, the new President, delivered an address on the Vagaries in Fashions of Treatment during the Past Quarter of a Century. He said that the birth of the science of biology was a great landmark in medical science and the foundation of gigantic changes in the fashions of treatment of disease. For from this dated the advent of scientific therapy and the ending of empiricism. Drugs were no longer the chief weapon in the management of disease, the great drawback being the frequent uncertainty of their action, the difficulty of estimating accurately their assumed effects, and that uncertain quantity—individual tolerance and idiosyncrasy. Now etiological factors, dietetic regulations, and physiological methods were engaging increasing attention in treatment. A continued and frenzied search was afloat for specific remedies, and earlier and more opportune recourse was had to surgical intervention in many disorders. There was no region of the body that could demonstrate this change in treatment so well as the abdomen, and it would seem that the surgeon had actually claimed this as his own private preserve. But Dr. Durno could not help thinking that the time had about arrived for a breathing interval and a shuffling of the cards between the surgeon and the physician. Scientific therapy had originated and had enhanced the art of medicine and materially augmented the resources of therapeutics. In 1893, after much careful clinical study, Behring introduced his antitoxin treatment of diphtheria, and probably in the whole history of medical science no discovery had surpassed this in therapeutic value. The success of antitoxin started off the fashion of serum-therapy treatment—soon to be followed by vaccine-therapy. As these methods of treatment, along with organo-therapy, were at the present time busily engaging the minds of the profession, they must wait until sufficient clinical experience had accumulated before they could ascribe to each fashion its proper value and place in therapeutics. The bursting of the coal-tar bomb, with its resulting clouds of derivatives of antiseptics, antipyretics, and analgesics, made it evident that there was money in this new drug fashion, and very soon manufacturing chemists took up the introduction of these synthetic products, employing physicians to experiment with them and publish their results as so-called contributions to medical science. This new fashion in pharmacy was responsible for the rooting out of the prescribing chemist, and the old chemist's shop had gradually become an emporium for the sale of products of large manufacturing chemists, the public treating themselves with drugs in the way suggested on the box or bottle; and, to a great extent, laziness or indifference on the part of the medical profession had fostered this now really serious state of affairs. It was absolutely bewildering to think of the numbers of new methods of treatment introduced into all branches of scientific medicine during the past quarter of a century, and at the same time it had been most pathetic to witness the melancholy and humble endings of most of them. The possibilities of therapeutics had been, and would be, greatly increased by the *science* of medicine, but something might be lost by the tendency of the present day to disregard the *art* of medicine.

ARMY AND NAVY MALE NURSES' COÖPERATION.—This excellent institution, of which Queen Alexandra is patron and Sir Frederick Treves president, was established four years ago for the purpose of finding employment for qualified male nurses discharged from the Navy and Army. The report for the year 1910–11, which was presented at the annual meeting of the coöperation in July, has now been reprinted for general circulation, and it shows most satisfactory progress. During the year under notice nearly 350 cases were nursed, an increase of 50 over the year 1909–10, and 42 nurses were kept in almost constant employment; while the receipts for the service of nurses amounted to nearly £3350, showing an increase of nearly £600. The offices of the Coöperation are at 47B, Welbeck-street, Cavendish-square, London, W.

Reviews and Notices of Books.

Funktionelle Diagnostik und Therapie der Erkrankungen des Herzens und der Gefässe. (*Functional Diagnosis and Treatment of Diseases of the Heart and Blood-vessels.*) Von Professor Dr. AUG HOFFMANN, o. Mitglied der Akademie für Prakt. Medicin und Direktor der Medizinischen Klinik in Düsseldorf. With 109 figures and one coloured plate. Wiesbaden: J. F. Bergmann. 1911. Pp. 483. Price 12 marks.

IN few branches of clinical medicine have greater advances been made as a result of the application of scientific methods than in that dealing with diseases of the heart and blood-vessels. The relative accessibility of the essential organs of the circulation to methods of physical and instrumental examination, the fact that the main phenomena of the circulation are subject to known physical laws, and the importance of an efficient circulation to the adequate functional activity of other organs, are probably chiefly responsible for the large amount of research which has been done in the directions thus indicated within recent years. Perhaps the most important outcome of this work is that we are no longer satisfied with an anatomical diagnosis in morbid conditions of the heart and vessels, but require in addition to appraise the functional efficiency of the circulation as a whole in every patient, or, in other words, the degree of compensation he possesses for his disabilities. It is obvious that this functional diagnosis is the essential preliminary to rational and effective treatment.

This aspect of the diagnosis and treatment of diseases of the heart and blood-vessels is the one which is prominently emphasised in the important book by Professor Hoffmann now under review. He begins by describing in full detail the indications afforded by the patient's history and subjective symptoms, and then gives the methods of ordinary physical examination, including the modern applications of the Roentgen rays to this purpose, together with the significance of the information obtainable from these methods. The evidence from palpation and auscultation in regard to the functional efficiency of the heart is discussed in detail, and then the various graphic methods are described, together with the interpretation of their results. In this connexion a clear and well-illustrated account is given of Einthoven's string galvanometer and of its application to the record of electro-cardiograms. Illustrative tracings are shown, and the method of analysing them is explained. Among other instrumental methods the graphic recording of the heart-sounds is described. A careful and interesting analysis of recent work upon conditions of cardiac irregularity is included in this section. The methods employed to measure the working capacity of the heart—viz., by the sphygmobolometer of Sahli, by the plethysmograph, and the tachecgraph—are described and illustrated.

After these general considerations the special diagnosis of abnormal conditions of the heart and blood-vessels is studied. The characteristic signs and symptoms of cardiac insufficiency are described under two headings, relative and absolute, the latter being applied to conditions in which there are signs of stress in the circulation, even at rest. The diagnosis of the various anatomical lesions of the myocardium, endocardium, and pericardium is reviewed, but in less detail than is common in English text-books, the reason being, as already mentioned, that Professor Hoffmann regards the question of the estimation of the degree of functional efficiency as of paramount importance. Diseases of the vessels and nervous disorders of the circulation are next considered, and here, again, the author devotes much

attention to the recognition of their effects upon the circulation as a whole rather than to their anatomical diagnosis. The subject of the functional treatment of the diseases of the heart and blood-vessels is dealt with fully. The general principles of treatment are explained, the uses of hydrotherapy and of electrical appliances are carefully examined, and the individual drugs employed to exert effects upon the heart and vessels are discussed. At the end of every section a long bibliography is appended.

We can strongly recommend this book as a scientific and suggestive work of reference. It summarises in admirable fashion the present state of our knowledge in regard to diseases of the circulatory system, and emphasises the importance of directing treatment to the patient's needs and not to his anatomical lesion.

The Practice of Surgery. By JAMES GREGORY MUMFORD, M.D., Visiting Surgeon to the Massachusetts General Hospital; Instructor in Surgery in the Harvard Medical School; Fellow of the American Surgical Association. With 692 illustrations. London: W. B. Saunders Company. 1910. Pp. 1015. Price 30*s.* net.

A MORE striking illustration of the present state of surgery could hardly be afforded than by the fact that a volume on "The Practice of Surgery" should commence with the abdomen (the first chapter dealing with appendicitis). There is no preliminary matter, no mention of the principles of surgery, no account of bacteriology—in fact, nothing is mentioned, but the reader plunges straight into appendicitis. This arrangement has been adopted intentionally by the author, who has taken up surgical diseases mainly from the aspect of clinical surgery, and has discussed their importance and frequency so far as possible with due regard to a proper sequence. It is assumed that the reader has had a preliminary training in the subject, and he is here presented with surgery as it is seen in practice.

This work is written energetically and with a disregard for conventional methods. It contains very much that is good and also much with which we cannot agree. It is abundantly illustrated, and the illustrations have been for the most part chosen wisely and well drawn. Some subjects are more fully treated than others, but on the whole the general impression left by the book after perusal is favourable. But it might have been well to express the opinions a little less dogmatically, for the student may be led to think that there is nothing to be said on the other side, while all surgeons know how difficult it is to say with certainty that one course is right and all others are wrong. An interesting illustration is a reproduction of Hinckley's painting in the Boston Medical Library representing the first public demonstration of ether anæsthesia at the Massachusetts General Hospital in 1846.

A Treatise on Diseases of the Eye. By JOHN ELMER WEEKS, M.D. London: Henry Kimpton; Glasgow: Alexander Stenhouse. 1911. Pp. 944. Price 30*s.* net.

THE author of the present work is one of the most prominent ophthalmologists in New York, and his name is familiar all over the world in the designation of the Koch Weeks bacillus, which he discovered almost simultaneously with, and quite independently of, Koch, and of the complete life-history and pathogenicity of which he was the first and exhaustive investigator. The promise of his early work as a pathologist has been fulfilled in his development into one of the foremost of ophthalmic clinicians, and it is not surprising that Dr. Weeks should desire to give to the world some of his views on the problems which have occupied the greater part of his life. The form in which he has chosen to present them has its advantages and its drawbacks. Among the former are the opportunity afforded for a consistent general purview of the whole subject, and the width of the appeal made by a text-book as compared with isolated papers in journals and society transactions. Among the latter, the most serious drawback in the design of a formal text-book is that it precludes a due expansion of the discussion of particular problems at the expense of others which have occupied less of the author's attention. Probably Dr. Weeks had this disadvantage in mind when he called his book a treatise and not a text-book; he thus obtains rather more latitude for the inclusion of some historical discussions and many operative procedures of questionable value, and can make reference to many rare diseases of little importance to the student. We think that the student should use the book chiefly as a work of reference, supplementary to one of the ordinary text-books, in which he will appreciate the proper perspective of ophthalmological details more easily. The expert will be well advised to add it to his library, on account of the references to original articles contained, though, of course, these are far from exhaustive.

The general scheme of the work is familiar. There are introductory chapters on development and anatomy; then a chapter on the general principles of optics by Dr. W. N. Souter. The chapters on diseases of the eye follow the usual anatomical classification, though the order adopted differs from most other books—disadvantageously, as we think. The chapter on movements of the eyeballs and their anomalies is written by Dr. Alexander Duane.

The printing is excellent; there are many original illustrations, mostly good, and a very large number of borrowed ones, duly acknowledged.

Genito-Urinary Surgery and Venereal Diseases. By J. WILLIAM WHITE, M.D., John Rhea Barton Professor of Surgery, University of Pennsylvania, and EDWARD MARTIN, M.D., Professor of Clinical Surgery, University of Pennsylvania. Ninth edition. Illustrated with 300 engravings and 14 coloured plates. London and Philadelphia: J. B. Lippincott Company. Pp. 1092. Price 21s. net.

THE appearance of nine editions of a book within ten years must go far to prove that it is fulfilling its mission, and this fact places it beyond the reach of detailed criticism. The subjects included within this volume fully justify its great size, even though it has now passed the thousand pages; and the points which we select for brief notice are mainly those where it seems to us that in yet future editions some revision might be advisable. In discussing the etiology of chancroid the authors, though apparently satisfied that it is due to Ducrey's bacillus, do not state the fact so clearly as to make it obvious to those who are not acquainted with it before. For urinary segregation Cathelin's instrument is praised and it is described as better than its competitors, but the authors agree that even it is not sufficiently accurate for a bacteriological differentiation of the urine. With this latter opinion we agree, for we are inclined to think that the trustworthiness of urinary segregators has been much over-estimated. With regard to the operation of preference for the removal of enlarged prostate we are told that by either route, suprapubically or through the perineum, the great majority of prostates can be removed, and, the authors continue, "the experience and aptitude of the operator with the method to which he is accustomed is of far greater importance in determining the method of procedure than the character of the prostatic enlargement." This is certainly true, but we do not think they have made it quite clear that the large masses of prostate projecting into the bladder are much more easily removed suprapubically than through the perineum. We fully concur with the opinion expressed that

vasectomy is likely every succeeding year to occupy a more and more restricted field in the treatment of prostatic hypertrophy. The account of syphilis occupies more than 230 pages, and it forms an elaborate and accurate account of the manifestations of this disease and is illustrated by about 60 drawings, some of which are in colour. Unfortunately, we have been unable to find any reference in the account of the treatment to "606," but it is possible that the book was finished before this method of treatment became widely known.

Symptomatic and Regional Therapeutics. By GEORGE HOWARD HOXIE, A.M., M.D., Professor of Internal Medicine and Dean of the Clinical Department in the School of Medicine of the University of Kansas. London and New York: D. Appleton and Co. 1910. Pp. 499. Price 16*s.*

THIS volume contains material collected for the course in general therapeutics recommended by the Committee on Curriculum of the American Medical Association. This course forms a transition between the laboratory and clinical work, and therefore more attention has been given to the discussion of the principles underlying the various methods of treatment than to an elaboration of the relative merits of the various drugs which have been introduced from time to time for the treatment of disease.

The first part of the book is occupied with a consideration of symptoms and their relief, and of the relations of symptoms to pathological processes. Thus the treatment of pain by various methods is chronicled at length, local and general anæsthesia being included under this heading. The treatment of "localised inflammations" is described, but the remarks are too brief to be of any practical value. Diseases affecting the various systems of the body are considered seriatim and the pathology of each condition is briefly reviewed, a distinction being made between symptomatic and specific treatment. In this way the importance of rational treatment is impressed upon the student, and constant recourse to empirical methods is avoided.

The advice given in regard to the therapeutics of various affections is sound and well expressed, but we consider that although this book may be read by the student as a preliminary guide to "treatment," it can hardly replace other manuals.

La Pratique des Maladies des Enfants. Vol. VII., *Chirurgie des Enfants, Appareils Digestif, Cardiaque et Pulmonaire, Organes Génito urinaires, Organes des Sens. (The Surgery of Childhood: the Surgery of the Digestive System, Heart, Lungs, Genito-urinary Organs, and the Organs of Special Sense.)* Par A. BROCA, Professeur Agrégé à la Faculté de Médecine de Paris; FROELICH, Professeur Agrégé à la Faculté de Médecine de Nancy; A. MOUCHET, Chirurgien des Hôpitaux de Paris; GUISEZ Assistant d'Oto-rhino-laryngologie à l'Hôtel-Dieu; and F. TERRIEN, Professeur Agrégé à la Faculté de Médecine de Paris. Avec 235 figures. Paris: J. B. Baillière et Fils. 1911. Pp. 540. Price, paper, Fr.14; boards, Fr.15 50.

THIS is a new volume of a valuable series of treatises devoted to the diseases of children. Like the preceding volumes of the system, it concerns itself mainly with diagnosis and treatment, and the names of the authors are sufficient to guarantee the high quality of the material. An article by Professor A. Broca, which serves as an introduction to infantile surgery, commences the volume. Professor Broca lays stress on the superiority of general anæsthesia over local anæsthesia for children, but he excepts cases in which there is hypertrophy of the thymus. He considers that almost all the deaths from chloroform in childhood are due to a faulty technique. Professor Froelich mentions that he prefers to operate for clefts of the hard palate at the age of 2½ years, but he performs the operation in two stages. Professor Guisez, who is responsible for the surgery of the ear, nose, and larynx, speaks very highly of direct bronchoscopy for the removal of foreign bodies, and mentions that he has had 25 successful cases out of 26 during the last seven years. The account of the surgery of the eye, by Professor F. Terrien, is very complete, and occupies nearly 200 pages; it deserves special mention. The illustrations in the volume are numerous and excellent, but in a work on the diseases of children it is surely a mistake to have some illustrations representing adults as patients, as in the figures of rhinoscopy. The book is a valuable volume of an important treatise.

The Reduction of Domestic Mosquitoes. By E. H. ROSS, M.R.C.S. Eng., L.R.C.P. Lond. London: John Murray. 1911. Pp. 114, with 18 illustrations. Price 5*s.* net.

YELLOW fever, dengue, and filariasis have been proved to be transmitted by two of the most common mosquitoes which worry the life of a healthy man, and which are an intolerable burden to the sick in hot countries. The object of this book is to bring to the notice of municipalities, town councils, health officers, and residents in warm climates the advisability of destroying all domestic mosquitoes, whether they are carriers of malaria or not.

Since 1899 Sir Ronald Ross has preached incessantly the need of extirpating mosquitoes by reducing the number of their breeding places, and in the following year Havana, a city of 250,000 people, began the campaign against gnats which has ended in the stamping out of yellow fever and malaria in many towns of the American continent. The mosquito net has hardly been necessary since 1903 at Ismailia; and the neighbouring town of Port Said, where the author lately held an appointment under the Department of Health of the Egyptian Government, determined in 1907 to destroy all the mosquitoes and to live in peace. In spite of the absence of sanitary laws dealing with this question, the presence of sea water only 3 feet below the level of the roads, 400 cellars in the town flooded with sewage from leaking cesspools, and a polyglot population under their own consular laws, which began by refusing to allow to sanitary inspectors access to the cesspools teeming with mosquitoes, this happy result was gradually accomplished at a cost of about £1000 a year, or 6*d.* per head of the population. The expense is nearly four times as great in Ismailia, partly because the population is only one-fifth that of Port Said, and also because Ismailia is rich in irrigated gardens, which have to be dealt with every week. For cesspools in Egypt equal parts of refined and crude petroleum mixed together are used, though any other oil which happens to be cheaper can be substituted. The general coöperation of the public must be obtained without the aid of the police, and it is all important to choose workmen of proved honesty, because each house in the town must be entered every week, in order to pour a litre of oil on every square metre of the surface of the cesspool contents, after which the latter must be well stirred with a stick to ensure an even film of oil spreading all over the surface. The householder has also to be warned against the dangers of stagnant water in his house and compound, and all flower vases, jugs, basins, buckets, and baths must be dried at least once a week. Special care must be taken with the kitchen, bathroom, and the cistern, which should be covered with a fine-meshed wire net of galvanised iron.

In Port Said, each mosquito gang, for it seems unnecessary to call three or four men working under a foreman a "brigade," deals with nearly 6000 houses every week, but many of these are huts or small shops which need but little supervision. Discretion and tact are always required; for

instance, in laundries the tubs of soapy water can be emptied on Saturday nights when the week's work is finished, and again the circulating cisterns of engines need not be clogged by petroleum, because the water in them is too hot for larvæ to breed there. The regular weekly visit discloses many insanitary defects, such as choked rain-water gutters, holes in trees containing rain-water, barge bilge-water, and other breeding places. If mosquitoes recur in a house which has been cleared, the responsible workman, whose name is inscribed on the door of the house, will have to be admonished, fined, or discharged. In Khartum, where the English can make their own laws, any householder is fined if mosquito larvæ are found on his premises, and lately several high officials have thus been punished. Similar fines exist in certain towns in the United States.

The author recommends mosquito reduction, because complete extermination is hardly possible, in Venice and other towns well known for this pest, and we believe that his book will be very useful to those who have not yet thought of ridding themselves of these irritating and sometimes dangerous insects. We doubt, however, if he is justified in claiming all the improvements in Port Said as the result of his energy in this one direction. He says the children "have some colour in their cheeks, and are able to play on the beach—it is a very different state of affairs. The place is buzzing, docks are being constructed, shipping dues are rolling in, and trade is progressing." Neither can we support his statement that the Egyptian Government has spent £249,000 during the past few years on fighting plague, and that "the result was *nil*."

LIBRARY TABLE.

Transactions of the South African Medical Congress (Twelfth Meeting). Published by the Transactions Committee of Congress, Cape Town. 1911. Pp. 324.—This volume of the proceedings of the Twelfth South African Medical Congress, held in November, 1910, contains many papers that reflect great credit on their authors. The Congress was honoured by the presence of the Duke of Connaught, whose reply to the address when at the opening ceremony especially bears witness to the devoted energies of medical men in the prevention, palliation, or eradication of disease, often involving a costly labour of research. His Royal Highness points out that such pioneers in the matters relative to disease should find their paths unhampered by financial obstacles. Dr. Charles F. K. Murray delivered the Presidential Address, in which he clearly pointed out the objects of such a congress. The work, although mainly scientific, embraces other matters claiming attention, such as the ethics of the profession, the attitude of its members towards each other and the public, and its responsibility towards the moral, intellectual, and physical well-being of the nation. He wisely suggests that at the time of the political union of South Africa a portfolio of Public Health should be created in the Ministry, and a resolution to that effect was submitted to the authorities unanimously. The section on medicine contains many admirable papers, amongst which may be emphasised that by Mr. A. Murray Gray on the Modern Treatment of Tuberculosis, which enters fully into all the recent methods for combating the disease. Dr. A. Garrow sends an important contribution on the Clinical Varieties of Mediterranean Fever met with in South Africa, in which he describes the following types: the acute malignant, the acute one-wave type, the acute undulatory type. Then follows a description of the subacute undulatory, the chronic, and the complicated types. The latter include pulmonary, pleural, hepatic, kidney, and nervous complications. We also may see cases simulating hip-joint disease and cases complicated by certain injuries and operations, and in this respect Dr. Strahan draws attention to the grave prognosis where Mediterranean fever complicates the puerperal state. The whole paper is well worth perusal. Dr. H. W. Reynolds writes on the interesting subject of ionic medication by electrolysis. Dr. S. P. Impey, a well-known authority on the disease, gives a paper on the Lepers of South Africa. He discusses the bacillus, points out the difference in prognosis between the tubercular and the anæsthetic forms, and draws attention to the rarity in South Africa of that variety wherein nodules occur on the trunk and the skin becomes hard and dry. The author holds that in anæsthetic leprosy only the nerves are affected, the other symptoms being of atrophic character. He also points out that nearly all authorities consider that there is hardly any danger of admitting to social intercourse lepers of the latter class. Dr. Impey first drew attention in 1902 to spontaneous cases of leprosy, which he believes occur much more frequently than is generally supposed. As regards segregation of lepers, he thinks this certainly should not be abolished, but the simpler form in vogue in Norway should be adopted. In the section on surgery will be found papers on Urinary Stone, by Dr. H. Temple Mursell; on Intestinal Obstruction, by Sir E Sinclair Stevenson; and an excellent paper on Some Factors Making or Marring the Success of Surgical Operation, by Dr. G. A. Casalis. Public health receives its due meed of attention. The special subject for discussion was the æstival diarrhœas of South Africa. This was opened by Mr. G. D. Maynard. The points he laid stress on were the need for simplification in nomenclature and more uniform methods of registration; the importance of the age factor; that the specific infection of food as a cause of the disease has probably been over-rated; and, finally, that the lowering of the body resistance due to improper feeding, climatic changes, insanitary conditions, &c., is of prime importance in the etiology of the disease. The author does not think that the agency of flies in the matter of causation as the chief factor has yet been proved. Dr. Garrow contributes also to this section a paper on the Etiology and Prophylaxis of Mediterranean Fever in South Africa, drawing attention to the part played by infected goats' milk, urine-infected kraal dust, and the fouling of hands and inoculation through abrasions with infected urine in handling the urine-soaked fæces of infected goats. Mr. H. A. Spencer writes on epidemic malaria a noteworthy paper, to which subject also Mr. Edward H. Philips contributes an excellent discourse. Many other praiseworthy papers in this report reflect the highest credit on our medical brethren in South Africa.

The Hunterian Lectures on Colour-Vision and Colour-Blindness. Delivered before the Royal College of Surgeons of England on Feb. 1st and 3rd, 1911. By Professor F. W. EDRIDGE-GREEN, M.D. Durh., F.R.C.S. Eng., Beit Medical Research Fellow. London: Kegan Paul, Trench, Trübner, and Co., Limited, 1911. Pp. 76. Price 3*s.* 6*d.* net.—These lectures were published in THE LANCET at the time of their delivery—viz., in our issues for Feb. 4th and 11th. Doubtless many of those especially interested in the subject—and, indeed, it is one of importance not merely to the ophthalmologist, but to every general practitioner—will be glad to have them in book form. The book contains several additional diagrams and illustrations which will help to elucidate the subject matter.

JOURNALS AND MAGAZINES.

Archivos Brasileiros de Medicina. Vol. I., Nos. 1 and 2. February and March, 1911. Rio de Janeiro: R. Gonçalves Dias.—These are the first issues of a new review, to be published monthly, with a minimum of 50 pages. The numbers will be alternately devoted to original work in, and

to a general review of, medicine. The first number, which is a specimen of the former class, contains original contributions and case reports, abstracts of articles and monographs, and book reviews. The "Supplementary Numbers," as those of the other class are called, contain a general review of matters of practical medical interest, a section of clinical reports, a permanent section on cancer, reports of medical societies, and other matters of professional interest. The last number of each year is to be devoted exclusively to a particular subject, the Problem of Syphilis having been selected for 1911. Each original article will have a *résumé* affixed in English, French, or German. In the first number Dr. Miguel Pereira and Dr. E. Gaspar Vianna report a case of blastomycosis which ran its entire course in less than four months and recalled in its rapidity and virulence bacterial septicæmia or bacteriæmia. The necropsy demonstrated the dissemination of the blastomycotic process throughout the organism, infecting, as it did, the pancreas, liver, lungs, mesenteric glands, joints, and bones. Numerous parasitic forms were found which seemed to characterise morphologically and biologically a new blastomycete. In the cultures a parasite of spherical form which produced mycelium developed. Inoculations into the ape, dog, roebuck, rabbit, and guinea-pig showed positive results. Other articles are: Two Cases of Madelung's Deformity, by Dr. Albaro Ramos; A Contribution to the Study of Uterine Fibroma, by Dr. Adolpho Possollo; A Contribution to the Applied Anatomy of the Prostate, by Dr. Benjamin Baptista; Nine Cases of Scurvy in Infancy, by Dr. Fernandes Figuiera; Responsibility in the Insane, by Dr. Henrique Roxo; Röntgen Diagnostics, by Dr. Toledo Dodsworth; A New Method of Blood-staining, by Dr. Joaquim Moreira da Fonseca; Reduplication of the First Sound of the Heart, by Professor Dr. A. Austregesilo; Clinical Reports of Benign Forms of Nervous Leprosy, by Dr. Juliano Moreira; Subcortical Sarcoma of the Right Parietal Lobe, by Dr. Ernani-Lopes; and Alternating Paralysis, by Dr. Joaquim Moreira da Fonseca. M. Pio Corrêa contributes an illustrated note on a Flacourtiaceous Parasiticide (Carpotroche brasiliensis Endl). There are several excellent illustrations and skiagrams. The character of the second number has been sufficiently described above.

The Child. Vol. II., No. 1. October, 1911. London: John Bale, Sons, and Danielsson, Limited. Price 2*s.* net, or 1 guinea annually.—Sir James Crichton-Browne's presidential address, delivered before the annual meeting of the Child Study Society at Halifax, Yorks, last July is the first article. He calls attention to the fact that 40 years ago he anticipated the present idea of the function of education—viz., to foster growth—by defining education, in his Education and the Nervous System, as the "guidance of growth." In this connexion he discusses the conditions influencing growth, mind and body growth, growth in different organs, and brain growth. He emphasises the importance of studying correlatively the growth of both mind and body. In an article on Ireland and Child Hygiene Sir John Byers points out the importance of child hygiene, describing the infant mortality as the index of social welfare and sanitary administration. He considers that the divergence between the excessive infant mortality among the poorer classes as compared with that among the better-to-do—notwithstanding that the mothers of the former class usually nurse their offspring, while those of the latter class do not—is due to removable conditions—viz., (1) the habits and homes of the people, and (2) maternal ignorance. The infant death-rate of Ireland, urban and rural, is discussed and compared with that of large cities elsewhere. He comments on school hygiene and tuberculosis in Ireland, and concludes with discussing the means to improve the hygiene of childhood. Mr. Arthur Greenwood discusses juvenile labour problems and suggests a line of reform. Mr. George Archibald Hamilton deals with the aim of religious education, which he describes as "to help the children to be overcomers [of obstacles]." He regards secular education in the schools as a psychological impossibility. Sir Francis Vane analyses the source of attractiveness to boys of the Scout movement, and says that it is clear that a movement which equally attracts the children of all races belongs to that category of things which are essentially universal, and protests against its limitation by the "village pumpists" to local ends and purposes. Miss Anita U. Boggs utters a plea for the forward child. Dr. Woods Hutchinson considers the effect of various well-meant experiments of philanthropy as a help or a hindrance in the diminution of infant mortality. He supports the care of infants by mother, aunt, or older sister as against institutional care, urges the displacement of the doctrine of content by that of fighting for betterment, protests against cheap foods, against the mother working up to the time of her confinement and neglecting her child afterwards for work, and against the indiscriminate urging of large families, contending that it is quality, not quantity, that should be reared. Mr. H. W. Armit describes the Child Welfare Section of the British Section of the International Hygiene Exhibition at Dresden.

The Bristol Medico-Chirurgical Journal.—To the September number Dr. George Parker contributes an interesting paper on Medical Organisation and the Growth of the Medical Sciences in the Seventeenth Century, illustrated by sketches of the lives of local worthies, among whom are included Cole, Sydenham, and Locke. Dr. A. Rendle Short writes on the End-results of Operations on the Stomach and Duodenum; he notes the number of cases in which an ulcer was diagnosed but was not found at the operation, severe hæmorrhage not being necessarily an indication of this lesion.

The Birmingham Medical Review.—In the September number Dr. W. J. McCardie discusses the advantages and disadvantages of Spinal Analgesia; his paper is not concluded in this issue. Dr. Leonard G. Parsons writes on Recurrent Vomiting occurring in Childhood, with notes of a fatal case. The condition is accompanied by the appearance of acetone bodies in the urine, and the treatment advised is administration of sodium bicarbonate and glucose. In a report on Infant Mortality in Birmingham the conclusion is reached that "the influence of industrial employment (of the mother) is quite small when compared with the influence of acute poverty ..... it is doubtful whether any further interference with the employment of married women would be at all beneficial as long as the acute poverty remains."

The Hospital, upon entering its twenty-sixth year of existence, has extended its scope in various directions, while the price has been reduced to 1*d.* weekly. It will henceforth be known as "The Worker's Newspaper of Administrative Medicine and Institutional Life, Administration, National Insurance, and Health." The issue for Oct. 7th was a special number, and contained articles of interest to those connected in various capacities with hospitals and kindred institutions, including a full report of the recent meeting of the British Hospitals Association at Manchester, and an editorial survey entitled "Twenty-five Years' Institutional Progress."

King's College Hospital Medical Society, which was founded in 1833, will open its season 1911–12 to-day, Friday, Oct. 13th, at 8 P.M., with an address on the "Use of Our Authority," by Mr. Stephen Paget, F.R.C.S. The chair will be occupied by Dr. StClair Thomson.

THE LANCET.

LONDON: SATURDAY, OCTOBER 14, 1911.

The National Insurance Bill.

A FORTNIGHT ago, in surveying the position of the National Insurance Bill, we found it to be certainly an anxious one, and recent events do not seem to have improved its prospects despite Mr. LLOYD GEORGE'S explicit statement that the Government would persevere with the measure. The amendments already passed by the House of Commons, while meeting in some respects the demands of the medical profession, have undoubtedly given great offence to the leaders of the Friendly Societies, and the word "betrayal" has been freely used by the representatives of these organisations. The Chancellor of the Exchequer, recognising the gravity of the situation and the necessity of reconciling so far as possible the rival claims of the medical profession and the Friendly Societies, held a conference at the Treasury on Monday last, to which representatives of the British Medical Association and of the societies were invited. No official report of the proceedings at this conference has been published, and in the circumstances it seems to us that little would be gained for either party by publicity. The objections of the Friendly Societies to the clause dealing with medical benefits are perfectly well known. They have been made at large and in strong language. Similarly the six cardinal points which the representatives of the British Medical Association are instructed to insist upon cannot be altered without reference to the members of the Association. All that it is possible to expect from the conference is, it seems to us, that the Friendly Societies having formulated their demands, the representatives of the British Medical Association should report how far those demands can be met without waiving any of the cardinal points. In the discussion which followed the presentation of the views of the Friendly Societies at the conference the representatives of the British Medical Association invited the societies to submit what they asked of the medical profession, but the medical secretary of the British Medical Association has disclaimed responsibility for a statement issued by the Press Association, saying that at the conference "a basis of settlement was reached." Mr. SMITH WHITAKER points out that he and the other representatives of the Association took every care to explain that they had no authority to enter into any arrangement of any kind, and that they could hold out no hope of any departure by the medical profession from the six cardinal points of its policy as already declared.

How much the medical profession will gain by even the maintenance in its integrity of the six-fold demand has always, of course, been a matter of doubt; and it is well that the medical profession should recognise this doubt before the measure is again before Parliament. Mr. ARTHUR MAUDE in a letter which we publish in another column reviews the present situation of the Bill in its relation to the medical profession, and examines critically the extent to which the six cardinal points have so far been met. He maintains in very able manner that little real concession has been granted by the Chancellor, the clear inference being that if the demands of the British Medical Association should be whittled down any further as a result of the conference now proceeding, the medical profession will have fought in vain. Our correspondent views the whole course of recent negotiations with suspicion. We do not share all his particular apprehensions. But we have never disguised our deep distrust of the introduction into the greater part of the medical service of this country of the contract system. This system has worked badly in our own experience of it, and cannot be regarded as a success in Germany; and it has throughout surprised us that a general acquiescence in its beneficence should have been expected of the medical profession by the public. For the present the British Medical Association and the Friendly Societies appear to have reached a place where one or other must yield, and where neither can do so; while the reconciliation of interests here will not make the Bill any more inviting to a large section of the medical profession. The British Hospitals Association, at its recent meeting at Manchester, heard the views of a responsible body of hospital managers and administrators, and the speakers unanimously declared that the Bill as it stands will seriously prejudice voluntary hospitals throughout the country, not only financially, but in their relation to the medical profession. The British Hospitals Association called on the Government to amend the Bill in order that the voluntary hospital system may not be swept away, and in so doing were speaking in the best interests of the science of medicine and of medical education.

The Difficulties of Diagnosis.

THERE are few opinions on medical subjects which are more strongly held by the non-medical portion of the population than the opinion that a physician or surgeon should be able to make a diagnosis of any case presented to him. For they hold that to a competent observer a diagnosis is simple and sure. Only a few years ago a medical man was fined for not notifying a case of small-pox, in spite of his statement that he was not satisfied that it was a case of this disease. The public fail to recognise that in many cases the making of a diagnosis is extremely difficult, and not rarely quite impossible; and they are ready to look upon any refusal to name the disease present as an acknowledgment of ignorance, while it may well be that the refusal is due to the wide knowledge of the observer. While it is true that rapid and accurate diagnosis is possible in cases where the signs and symptoms are striking and characteristic, nearly always careful examination is necessary, and the diagnostic methods which have been introduced of late years may have to be called into requisition before a decision can be come to with practical certainty. Increased facilities have brought with them increased responsibilities. And where the chief cause of difficulty in diagnosis is the absence of any marked symptoms, the medical man, with

all the aids now given him by physics, chemistry, and biology, may well remain in doubt as deep as any that would have involved his predecessors of fifty years ago. There may be some rise of the temperature and some malaise, and some indefinite and shifting pains, but without more definite signs or symptoms an accurate diagnosis is impossible. For cases such as these the diagnosis of "febricula" is regarded by some as satisfactory, and "influenza" has been of great utility in cases where no materials for a real diagnosis are at hand. Oftentimes these are mere screens to hide the absence of a diagnosis, and though they cannot be entirely condemned, for they may soothe and satisfy the anxious mind of the sufferer, they can hardly be regarded as other than unsatisfactory. The onus of these expressions of pious and semi-informatory opinion rests with the public who, without such expressions, condemn the medical man out of hand.

There may be present in a case some striking symptom, such as the pain in a case of sciatica, which will justify a diagnosis, but even in so simple a matter as this, where the pain is the expression of a neuritis, it must not be forgotten that almost identical symptoms may follow from the presence of a tumour—say—in the pelvis pressing on the sciatic nerve. Nowadays the medical man who looks no further before him than is implied by the diagnosis of sciatica may satisfy his audience, but not his conscience. Perhaps the most troublesome cases to diagnose are those in which two absolutely independent lesions or morbid states co-exist. It is an established rule in diagnosis that the simplest explanation which will account for all the symptoms and signs present should be accepted, yet it will happen that though two distinct lesions are present they may give rise to symptoms explicable by one diagnosis. As an instance we may mention a case in which definite syphilitic ulceration is present on the face, while a localised enlargement of the tibia also exists. Here every surgeon would feel justified, in the absence of further evidence, in diagnosing the lesion of the tibia as syphilitic in origin, and yet in a case of this sort which was recently brought to our attention, though the ulcers were certainly syphilitic, the swelling of the tibia was due to a central sarcoma. In the pages of THE LANCET have appeared numerous instances in which an error in diagnosis has been due to the mixed origins of the symptoms, and doubtless many such cases must occur to the minds of our readers. Another occasional but very important cause of diagnostic mistakes is poisoning. In such cases the value of the many precise aids to diagnosis now possessed by the medical man may become very obvious; closer investigation will show that conditions which might have one reason are better explained by another. It is such careful revision and correction of diagnosis that, for example, the poisoner has to dread. It is so rare for a medical man to meet with cases of sub-acute or chronic poisoning, either accidental or intentional, that he is inclined to recognise in the condition of the victim some combination of signs and symptoms that can be explained on more usual grounds. Many trials for murder have shown that cases of homicidal poisoning have escaped recognition, even though treated by very competent medical men, because no suspicion of poisoning was excited in circumstances which a more common diagnosis appeared to fit. We can all see how important it is that the possibility of poison should be present to the physician's mind upon the necessary occasions, but the same importance exists, though not in so dramatic a form, when obscurity occurs in any clinical problem.

The difficulties of diagnosis can never be fully appreciated by the public, and just as the English law supposes that every man knows the whole of the law, so does it suppose that every medical man knows the whole of medicine. Which is absurd. The progress of science has placed in our hands many diagnostic means quite unknown a few years ago. The Roentgen rays reveal to us differences unascertainable by other means, especially in regard to the bones and to foreign bodies; the recent introduction of the bismuth method has made the X rays applicable to many parts of the alimentary canal and thus has widely extended their usefulness. The employment of tuberculin and mallein, and other similar substances, has become so certain a method of diagnosis as to be utilised in agriculture. Still more recently Wassermann's test has been introduced, and when employed with due care it is invaluable, and often decisive. The value of differential blood-counts is also great for diagnosis and prognosis, words which would describe much other pathological procedure which we do not mention. But with all these adjuvants the greatest care has to be used in solving the complex problems of disease, while no amount of laboratory technique will absolve the physician from ordinary general precautions in making a diagnosis. We chronicle elsewhere the death of Dr. JOSEPH BELL, the Edinburgh surgeon, whose elaborately developed powers of observation revealed to him the environment in which many of his patients lived and moved. JOSEPH BELL, be it remembered, was a thoroughly good scientific surgeon. The detective faculty may be of the greatest value to the medical man when reinforced by the ability to make use also of every aid which science can supply. Without such aid failure will result, while, on the other hand, elaborate pathology unsupported by ordinary observation is deprived of half its value.

Annotations.

"Ne quid nimis."

THE GALTON LABORATORY OF EUGENICS.

THE importance of the study of eugenics can hardly be exaggerated, since the bias of future legislation will almost certainly be in the direction of social reforms; and if such legislation is to be anything more than the passing of palliative measures it must be based on accurate data. Besides laying the foundations of the science of eugenics Sir Francis Galton himself endowed the Research Fellowship in Eugenics in the University of London, and the Society of Eugenics, which was formed by his friends, is zealously carrying on that good work. Sir Francis Galton also left the residue of his estate to the University of London for the endowment of a professorship and laboratory for national eugenics, and in his will he expressed the wish that the University would see fit "to preserve the capital thereof wholly, or almost wholly, intact, not encroaching materially upon it for cost of buildings,

fittings, or library." In order to carry out the wishes of the testator, the income from his bequest being insufficient to cover both endowment and adequate buildings, Lord Rosebery, the Chancellor, Sir William J. Collins, the Vice-Chancellor, Sir Edward H. Busk, chairman of Convocation and of the Galton Laboratory Committee, Dr. Henry Miers, the Principal, and other officials of the University of London, have issued an appeal for £15,000 for the provision of a Galton Eugenics Laboratory at University College, Gower-street. The appeal points out that the scope of the science of eugenics and the work of the laboratory have been defined as "the study of these agencies under social control that may improve or impair the racial faculties of future generations physically and mentally." In accordance with the suggestion of Sir Francis Galton, Professor Karl Pearson, F.R.S., has been appointed first Galton professor, and he is assisted by a staff of highly trained workers who now find very insufficient accommodation in a few small rooms temporarily placed at their disposal at University College. The output of the laboratory in the form of original investigations has been very large, and attention is called to the fact that already influential movements are on foot for the academic recognition of eugenics and the establishment of similar laboratories in both America and Germany. The small laboratory, consisting of two rooms only in the applied mathematics department at University College, is consulted very largely by medical officers of health, by school medical officers, and by independent medical men engaged in statistical problems. On the ground that the institution has already been of great value and will render increased public service with its fuller development, the University feels justified in sanctioning an appeal for such external aid as will enable its staff to carry out effectively this portion of their functions. At the present time the laboratory is in possession of material received from educational and health authorities in all parts of the country, which alone would require three or four full years' labour for the existing staff to analyse and publish, and the bulk of it has direct bearing on the most important social and national problems of the day. No better memorial to the late Sir Francis Galton could be established, and we heartily endorse this appeal. Sketch plans of a new laboratory by Professor F. M. Simpson, F.R.I.B.A., are affixed to the appeal, and contributions and promises of support will be received by Sir Edward Busk, University of London, South Kensington, S.W.

THE ALBUMIN REACTION IN TUBERCULOUS SPUTUM.

THIS reaction is stated to be invariably present in cases of tuberculous disease of the lung, even in its early stages when it may be difficult or impossible to discover tubercle bacilli in the sputum. The technique of the reaction is exceedingly simple. 5 c.c. of the sputum are mixed with 20 c.c. of physiological salt solution in a test-tube; 5 or 6 drops of acetic acid are added and the whole well shaken up and then filtered. The filtrate is then tested for albumin by heat or nitric acid.[1] Lesieur and Prirey[2] find this reaction present before the appearance of any physical signs in the lungs in 75 per cent. of cases, and declare it a more useful test than the microscopic examination of the sputum. In miliary tuberculosis it is not constantly given, nor in pleurisy. It is present in acute lobar pneumonia due to pneumococci during the attack; its persistence in this disease during convalescence points to the probability of a new focus of infection or a complication. The reaction is found also in acute pulmonary œdema, acute congestion, and acute broncho-pneumonia. As a rule, it is negative in acute bronchitis, and it is negative in chronic bronchitis and in emphysema. In cardio-renal cases it is often positive. They give 840 observations from various authors in which the reaction was positive in 100 per cent. of cases confirmed by microscopic examination of the sputum for tubercle bacilli, in 82 per cent. of cases of probable pulmonary tuberculosis, and in 37 per cent. of cases of non-tuberculous sputum. They find that the intensity of the reaction is in direct proportion to the importance and gravity of the lesions and the abundance of tubercle bacilli, and so consider the reaction to be valuable in prognosis as well as diagnosis. A negative reaction would appear to exclude pulmonary tuberculosis.

THE PAST SUMMER.

THE statistics below have been compiled from observations published month by month by the Meteorological Office and may consequently be regarded as accurate. They comprise the mean temperature, the total amount of rainfall, and the total number of hours of bright sunshine for the three months, June, July, and August. The comparatively slight excess of the temperature over the average may be noted; the figure is in many places no

† Sunshine in Phœnix Park.

more than about 3°. In July and August, however, it was from 5° to 6°, or even more, over a very large part of England, and it is owing to the fact that June was very little warmer than the normal that the excess of the three months is relatively small. August was a little hotter than July in nearly all parts of the kingdom, and considered generally it was the hottest of which there is any record. The metropolitan area experienced the greatest heat, and this was followed rather closely by Jersey and Margate, while the coolest regions were the north of England, Scotland, some parts of Wales, and Ireland. The periods of greatest heat were July 22nd and August 9th. On the former date the sheltered thermometer reached 90° and above in very many localities, the highest readings being 96° at Greenwich and 97° at Epsom, while on the latter there were many readings above 95°. At Canterbury, Epsom, and Raunds readings of 98° were recorded, at Isleworth 99°, and at Greenwich 100°. This last figure, however, is, perhaps, not strictly comparable with those recorded elsewhere, as it appears that at the Greenwich observatory the form of the sun screen in use is not of the same type as those employed over the kingdom generally. The duration of sunshine, like the temperature, was everywhere in excess of the average, the excess in several localities of the south amounting to between four and five hours a day. There were, nevertheless, some districts where the excess was much less, the most noticeable being Nottingham, the Scilly Isles, and Dublin. Of all the records given in the table that at Glasgow was the lowest and that at Jersey the highest, the difference being represented by four hours daily. Except at Scarborough, where June was wet, the droughty condition on the mainland is well shown by the statistics. In East Anglia, Kent, and along the south and south-west coasts rain fell on no more than 20 days at the most, many places in those districts reporting a figure even lower. The driest places given in the table were Torquay, Bath, Margate, Clacton, and Yarmouth, each station receiving the small aggregate of three inches or less, a quantity wholly inadequate for three months of hot sunshine. Ireland, Scotland, and the northern parts of England were more fortunate, although even there the total fall was generally far short of the average. Of the four stations representing London it will be seen that Hampstead was the least warm both during the daytime and at night, and that it was somewhat less sunny than both Kew and Greenwich.

WHERE CHEMISTRY AND MEDICINE MEET.

IN his Presidential Address delivered to the Obstetrical and Gynæcological Section of the Royal Society of Medicine, a full abstract of which is published in our present issue, Dr. Amand Routh advances cogent reasons for encouraging coöperation between the physiological and pathological chemist and the obstetrician. Dr. Routh shows that obstetricians are at a standstill as regards the nature of the bio-chemical changes in the blood which influence the cyclical functions of menstruation and ovulation, and of those blood conditions which appear to encourage the implantation of the fertilised ovum and induce the onset of labour and lactation. Very little is known also of the autotoxæmias which may cause such toxic obstetric troubles as hyperemesis gravidarum, puerperal albuminuria, eclampsia, acute yellow atrophy of the liver, chorea gravidarum, and puerperal insanity. The fact that blood serum from pregnant women has different qualities from that of other women is indicated in several ways, but the physiological chemist has not yet discovered either the chemical constitution or the molecular structure of the substances concerned. Thus it is said that the serum of a pregnant woman hinders the proteolytic ferments, such as trypsin, and that pregnancy can be diagnosed by this fact. It has been stated by Krause and Graff, of Vienna, that placental serum has a remarkable power of destroying cancer cells. Stern has shown that whereas in healthy non-pregnant women 65 per cent. gave positive reaction to the cutaneous tuberculin test and 14·5 per cent. to the conjunctival test, the cutaneous reaction at the end of pregnancy diminished to 30 per cent. and the conjunctival reaction results were consistently negative. To the same category of observation we may refer the fact that pregnant women appear to have a sort of immunity from scarlet fever, for Olshausen could only find instances of seven cases of scarlet fever during pregnancy, as compared with 134 within one week after delivery. Dr. Cuthbert Lockyer, again, has investigated the influence which the lutein tissue formed in the mature Graafian follicle can exercise. It is known that excess of lutein tissue, sometimes in the form of lutein cysts, is associated with hydatidiform degeneration of the chorion, and it is known that destruction of the corpus luteum in rabbits prevents implantation of the fertilised ovum by preventing the development of the trophoblast, and these and other facts seem to show that lutein tissue is one of the elements of the ovarian internal secretions which, through the blood, may exercise influence on the cyclical functions of the uterus, and on the normal or abnormal implantation of the ovum. The effects on the menstrual function of disordered internal secretion of the other ductless glands, in such diseases as myxœdema, Graves's disease, cretinism, and acromegaly, are to some extent familiar. Altered metabolism in the placenta or Graafian follicles is believed to be the cause of the various autotoxæmias which cause eclampsia and other parturient or puerperal diseases. The fact that puerperal eclampsia in women and puerperal apoplexy in cows can sometimes be cured (the latter in 98 per cent. of cases) by injections of antiseptics or even oxygen into the mammary glands, suggests that disordered metabolism of those glands also may at times produce a virulent toxin. Such a difficult blend of sciences as physiological and pathological chemistry cannot be undertaken except by experts, and Dr. Routh is of opinion that no real advance will be made in our knowledge till special laboratories for these subjects are established in our medical schools, and effort is thus made to discover the nature of the substances concerned, and their appropriate prophylaxis and antidotes. The question as to how this chemical branch of pathological research is to be provided is likely to prove difficult. Inasmuch as the work is required for the correct diagnosis and efficient treatment of the patients in hospital, it is not only rational, but just, that the hospital, rather than the medical school, should bear the expense, but it is not at all certain that this view would be taken by some of the lay authorities on hospital management.

ACUTE NEPHRITIS FOLLOWING THE INJECTION OF SALVARSAN.

THE untoward events which may follow the administration of salvarsan are almost exclusively associated with the intravenous mode of injection, and it is also possible to argue that many of them (nerve-deafness, for instance) are as likely to be due to the disease as to the drug. However, when all such allowances have been made, there still remains a residue of evidence as to the possible toxicity of salvarsan. Two cases, reported by Dr. H. Tucker of Philadelphia in the *Therapeutic Gazette* for September, go to show that the intravenous injection of salvarsan may speedily be followed by acute nephritis. The first case was that of a man, aged 30, who came under treatment for a hard penile sore with inguinal adenitis. His general condition was good, and his life had been

one of uninterrupted health until he acquired syphilis. A week before the injection of "606" was given he presented a characteristic secondary rash. The urine is reported on this same date as containing a trace of albumin and a few leucocytes, but no casts. The Wassermann test was positive. A dose of 0·6 gramme of salvarsan was given intravenously. In an hour the patient was vomiting and the temperature had risen to 101·2° F.; there was a large watery evacuation of the bowels. On the following day there was complete suppresion of urine, none being withdrawn even by catheterisation; by the evening the patient was very dyspnœic, and by midnight he was dead. No post-mortem examination was made. The second patient was also a fairly healthy man, aged 24; he was poorly developed and took spirits to excess at times, but apart from these facts his condition was apparently normal, except for the evidence of syphilis, which brought him under Dr. Tucker's care. He was in the secondary stage, having already undergone an inadequate course of treatment several months before. The urine was normal, containing neither albumin nor casts. Accordingly, after the Wassermann test had shown a positive result, 0·6 gramme of salvarsan was given by intravenous injection. Two hours later excessive vomiting began, with copious watery motions; the temperature was 105°, but this fell in 18 hours to 96°. No urine was passed, in spite of active treatment, for 24 hours following the injection. The mental processes were clouded and there was fleeting delirium. A specimen of urine collected by catheterisation on the day following the injection presented all the features of acute nephritis: blood and casts were found, and the specific gravity was 1030. Within a week, however, all the abnormal constituents had disappeared together with the symptoms. It seems impossible to escape the conclusion, particularly in regard to the second case, that salvarsan administered intravenously can provoke acute inflammation of previously healthy kidneys.

THE PHYSIOLOGY OF THE MARCH.

THE danger of heat-stroke from a heavily clothed person taking severe exercise on a warm day, particularly on a warm, moist day, is not generally appreciated, though fatalities have resulted at military manœuvres and operations. In an interesting article published in the *Journal of the Royal Army Medical Corps* for July Lieutenant-Colonel C. H. Melville, R.A.M.C., has lucidly discussed this danger in particular and the physiology of the march in general. He aptly compares the human body during exertion to a petrol or other internal combustion engine. The nervous impulse corresponds to the spark and the combustion in the muscles of certain constituents (consisting of carbon and hydrogen) to the explosion of the petrol. In both not only is work done, but as a necessary concomitant heat is generated and provision is made for its dissipation. In the body it is carried by the blood-stream to the surface, where it passes off by evaporation of moisture, radiation, and convection, of which the first is the most important. In the motor-car a water circulation is provided by which the heat is removed from the engine to the radiator, where it passes off. If the dissipation of heat is interfered with fever or heat-stroke is produced in man, an over-heated engine in the car, and in both serious injury may result. During severe exertion the rise in temperature is considerable. In a series of observations Dr. M. S. Pembrey and Captain Parker, R.A.M.C., found that in soldiers marching under varying conditions of load the temperature rose on an average 2·3° F. Such a rise is physiological and may be regarded as a danger signal. A temperature of 103° may be taken as the point where danger begins. Taking the normal temperature at rest as 98·6°, man has then a margin of safety of 4·4°. Taking the normal temperature of exercise as 101 6°, the margin is reduced to 1·4°, and here the danger lies. The danger is much greater in the soldier marching than in the civilian, because the civilian is at liberty, by varying his clothing, his pace, and load, to minimise the production of heat and facilitate its dissipation; the soldier is not. The importance of the load carried is shown by an experiment on the same man on the same march, on level ground on different days of approximately the same temperature. On the first occasion he was in drill order and his temperature rose less than ½°. On the second occasion he was in marching order, and his temperature rose 1°. If the load be materially increased to, say, 60 pounds, and the march long, and the conditions of weather unfavourable, the temperature may rise considerably. The German physiologist Zuntz has observed that a march of 15 miles with a load of 68 pounds sent up the temperature of men to 102·5° and higher. Those whose temperature rose to 103° or more had flushed purple faces and a vacant stare, and were obviously on the verge of breaking down. A load of 48 pounds on a very hot day had the same effect in raising the temperature as a load of 68 pounds on a cool day. The temperature produced is affected by the pace in two ways. Suppose a certain load is carried a certain distance in ten minutes, and again in five minutes. In the second case only half the time is given to dissipate the heat produced, while more heat is produced because the human body engine, like all other engines, has a normal speed at which it works with the greatest economy. Any variation above or below normal is uneconomical, and more heat is produced in proportion to the work done. All clothing interferes with the dissipation of heat because it interferes both with the evaporation of perspiration and with radiation. Even a slight difference in clothing is important. Five men were marched in drill order on two occasions—on the first with, and on the second without, their jackets. In the former case their temperatures rose 1½°, in the latter 1°. The obvious corollary is that soldiers should be ordered to open their jackets during severe exertion. Yet this is often neglected at manœuvres. A historical instance of the effect of difference of clothing on the endurance of troops is furnished by the attack on Chin-Kiang-Foo in the first Chinese war. The 9th regiment, healthy and strong, having just landed, ascended the heights dressed according to regulation. The heat was intense, and numbers fell dead from heat-stroke. The 18th, 49th, and 55th regiments, equally exposed to the sun, but with their jackets opened and stocks removed, did not lose one man from this cause.

TUBERCULOUS OSTEOMYELITIS OF THE SYMPHYSIS PUBIS.

IN the *Canadian Medical Association Journal* for September Dr. Francis J. Shepherd has reported an interesting case, describing it as one of tuberculous osteomyelitis of the symphysis pubis. A telegraph operator, aged 33 years, was admitted into the Montreal General Hospital on Jan. 26th, 1911, suffering from a large swelling in the lower abdomen. Excepting an attack of rheumatism he always enjoyed good health. Fourteen months before admission, while lifting hay, he gave himself a wrench, he thought, of the right hip. After two days the pain subsided, but three weeks later he again had sharp pains in his right hip when he walked or spread his legs apart. He limped until March, 1910, when he sought medical advice, under which he improved, but soreness still remained in the hip-joint, especially when he abducted his leg or when he lay on his right side. Flexion and extension were free and painless. In November, 1910, he noticed a small lump under the skin midway between the umbilicus and symphysis pubis.

It was of about the size and shape of the little finger and lay transversely. It was not tender or painful. He did not suffer from night sweats or lose weight. The swelling increased considerably and thinking that it was a hernia he wore a truss which, he said, gave relief. The pulse and temperature were normal. On examination a freely moveable mass extending two and a half inches on either side of the middle line was found between the umbilicus and symphysis pubis. The skin was not involved and there was no heat or redness. The swelling protruded from the abdomen and seemed to be external to the muscles. It fluctuated in the centre. Rectal examination revealed nothing. The right hip joint was normal in appearance and movement. There were no dilated veins. Under anæsthesia an incision was made above the pubis and a large quantity of flaky odourless pus was evacuated. On inserting the finger a large cavity was felt in the symphysis, containing a sequestrum and some cheesy matter. The sequestrum was removed, the cavity scraped out, and the opening closed. Another opening was made directly over the cavity, through which iodoform gauze packing was introduced. After a few days this was removed and bismuth paste was introduced. The wound healed rapidly and the patient was discharged on Feb. 28th able to walk, and without pain in the hips or pelvis.

MORTALITY IN A PUBLIC SCHOOL RECORD.

A GATHERING of "Old Boys"—former scholars of some particular school—is both a gay and a sad affair. They meet together, once a year it may be, at the Old Boys' Dinner, and one espies on every hand the familiar faces of one's early youth, mounted on incongruous or decrepit bodies. Where there is no excess of intellect—and who will be so bold as to say that public-school life in the fourth and fifth forms promotes intellectuality unduly?—where, too, the emotional life has been *nil*, the average Briton's face changes very little in the course of a life-time. It is possible to recognise, after the lapse of some forty years, the face of Jones IV., say, whom one last saw in the midst of some sanguinary school-boy fight at "the back of the fives courts" at the old school. The face will appear almost as boyish as of yore, save that, perhaps, it will be thatched with scanty grey hair, though its pedestal, the human frame, will display varying losses of symmetry. The ageing man, however, is more impressed by what he does not see than by what he does see on these occasions. He now misses his friends. After the age of 40 the mortality of the public school-boy begins to be apparent. An admirable contribution to the literature of school registers, the third edition of "The Register of Tonbridge School from 1826 to 1910," has just reached us. The editor is Mr. H. E. Steed of H.M. Office of Works. From this book it becomes obvious that since the "seventies" and early "eighties" death has been singularly busy among the Old Boys. Of what do public school-men die? From the data contained in a school register it is hard to say, but it is possible to infer much from the known characters of the deceased as well as from the incidence of their deaths. We therefore invited the opinion of an old Tonbridgian of the indicated seniority. From him it appears that Tonbridge some 30 or 40 years ago sent quite 40 per cent. of its *alumni* to India or the colonies, and had therefore to bear a large share of the "white man's burden," spoken of by Kipling, and much of its mortality has, presumably, been due to tropical disease. Of an entry of 35 boys into Tonbridge School in September, 1874, one-fifth has departed into the land of shadows. The first form, of which our informant was bottom boy, numbered 18, of whom the eldest is now 51 years old. Two of these have died—the one killed "while in pursuit of Lobengula," while the other, a well-known Congo pioneer under the late H. M. Stanley, succumbed to influenza in West Africa in 1891. The sixth form of that date, September–December, 1874, naturally shows a greater mortality, for the sixth-form boy is, on the average, 18 years old, while the average age of the then lowest form at Tonbridge was 10 or 11 years. Of 11 sixth-form boys 3 have died, and 2 of these died in India and China respectively. Roughly speaking, of the whole number of boys mentioned in this register who were born between 1860–1862—that is to say, about 50 years ago—5½th have died. In other words, 36 or 37 have died out of a total of 190. If from the actuarial point of view the average seems high, it should be borne in mind that of the 36 or 37 at least 20 have died abroad, in Burma, Manitoba, India, sometimes by accident or from disease contracted abroad, as in the case of military men or of an overworked medical officer, like the late Allan Euan Grant, M.B., C.M. Edin., of Madras, who returned to England to die from diabetes in 1902. Of the remaining 16 or 17, one heroically sacrificed his life for a child. This was Francis Stanhope Hawkins, M.B., F.R.C.S. Edin., born 1861, who as house surgeon of Guy's Hospital, died from diphtheria in September, 1888, "contracted while clearing the tube inserted in the throat of a child." He is therefore most honourably out of court. Of the rest, one died from scarlet fever at Keble College, Oxford, one from phthisis, and two while still at school. Much has been written about the after-lives of athletic boys and of vicious boys, some good people writing as if these classes were necessarily the same and some as if they were necessarily different. The perusal of this register does not tend to convince one who remembers something of the boys recorded to hold either that too much athleticism entails an early mortality, or that the kind of youth, darkly referred to by the late Dean Farrar in a certain disagreeable chapter in "Eric, or Little by Little," is more prone to die young than his fellows. The *mauvais sujet* bulks no more largely among the deaths than among the surviving school successes. Many of those who die early are worthy and blameless clergymen; and, *per contra*, among the plumes in the school cap, some of them men of adventure, are those who in their day were voted boys of poor spirit or prigs. A prig, indeed, is often a man of individuality, possessed, in a marked if sometimes perverse kind of way, of that rare quality—moral courage. These school records, like old school gatherings, produce mixed feelings of pleasure and pain to those who read them with personal knowledge, but from an ethnological point of view they have their value.

THE RELATION OF THE ORGANIC PHOSPHORUS CONTENT OF VARIOUS DIETS TO DISEASES OF NUTRITION, PARTICULARLY BERI-BERI.

IN these columns we have from time to time in recent years reported the advances which have been made in our knowledge of beri-beri, which had been until quite lately a most mysterious disease. In the Malayan peninsula and archipelago, as also in the Philippine Islands, many opportunities have been afforded for investigation into the nature of this malady, and much of what we know has come from that quarter. The disease, as it occurs in the Far East, is now generally recognised to be due to a dietary of white rice from which the pericarp of the grain has been removed in the process of "polishing" or milling (the pericarp containing the bulk of the phosphates and other salts), so that the disease is easily prevented by the use of a less highly milled or polished rice, one, in fact, that retains at least a

portion of the pericarp; and beri-beri can also be cured simply by administering with the food of the patient a portion of the "polishings" which are removed from rice in the milling process. In an article in the recently issued number of the *Annals of Tropical Medicine and Parasitology* (Series T.M., Vol. V., No. 2), published by the Liverpool School of Tropical Medicine, Dr. G. C. E. Simpson and Mr. E. S. Edie give an account of some experiments which they had carried out in connexion with the subject. The writers allude to the valuable work done by Schaumann and give a most interesting summary of that investigator's conclusions upon the results of his experiments on animals. They consider that his work has not received the attention in this country that it deserves. Schaumann in 1908, and Fraser and Stanton also a little later and quite independently, discovered that diets which produced peripheral neuritis were invariably poor in phosphorus, and that substances which have the power of preventing this neuritis, such as rice-meal, wheat-bran, katjang beans, yeast and testicular extract, are rich in that substance, so that the smaller the percentage of a diet in phosphorus the greater is its influence in producing beri-beri in man, or neuritis in fowls. It has already been shown by experiments that the animal body has not the power to synthesise the organic phosphorus compounds necessary for the life of the cells from phosphorus-free proteins and inorganic phosphates, but that animal life is dependent for these substances (as for proteins and carbohydrates) on the synthetic powers of the vegetable kingdom. Schaumann as a result of his experiments has formed the opinion that spontaneous or experimental polyneuritis in animals appears to be a disease of metabolism, attributable to the lack of some specific organic phosphorus compounds the identity of which, however, is still uncertain. As regards the form of beri-beri which occurs on sailing-ships, it is pointed out that many of the articles of diet carried on long voyages—such as white rice, white bread, and potatoes—are poor in phosphorus, and that salt meat loses 50 per cent. of its phosphorus by the combined action of the pickle lye and of the water in which it is boiled. Peas and other legumes as a result of a long voyage become mouldy, as well as hard and resistant to cooking even with soda. Schaumann's view seems to be that scurvy may be due to stale vegetables and ship beri-beri to the use of rotten or stale meat, the important factor being the lack of organic compounds of phosphorus. It is also worthy of mention that the preserved meats may have been "denaturised" by excess of heating in the process of preserving. Infantile beri-beri is known to be very common in the Philippines, Japan, and elsewhere. Schaumann's explanation of its cause is that it is associated with a great diminution of phosphorus in the mother's milk, especially in organic combination, and also associated with phosphorus hunger in the mother, resulting in a retention and sparing of phosphorus. Dr. Simpson and Mr. Edie have confirmed Schaumann's conclusions so far as their own experiments have extended. These, however, are to be continued, and a further report will in due course be presented. They believe that in the majority of cases tropical beri-beri is due to a deficiency of organic phosphates in the diet, but in occasional cases it may be due to deficient absorption of organic phosphates by the alimentary tract, or to bacterial infection possibly splitting up the phosphates before absorption, or interfering with the absorptive power of the intestine. They suggest, also, that a whole cycle of other diseases have in all probability a similar etiology, and that among these infantile scurvy, rickets, osteomalacia, &c., may be included. Lastly, the writers discuss the danger of white bread to English children. White bread has given rise to polyneuritis in fowls fed upon it; and as the phosphates are removed with the bran it is possible that children fed largely on such bread might develop disease as the result of deficiency of organic phosphorus in the diet. It is somewhat curious that the wheat-bran rich in phosphates is given to cattle for the purpose of fattening them. Dr. Simpson and Mr. Edie advocate the substitution of wholemeal bread for the white variety. We are not prepared wholly to endorse this recommendation, but there is much material for thought in this interesting paper.

THE ROYAL SOCIETY OF MEDICINE AND DENTAL RESEARCH.

IT has long been felt that dentistry, which has made such wonderful strides within comparatively recent years, would make still more rapid progress if its students could be encouraged to devote their time to research work. Unfortunately, however, few men have the time and money necessary for the pursuit of investigations which are in themselves unprofitable from a monetary point of view, and the Royal Society of Medicine is to be congratulated on having instituted grants in aid of scientific research in connexion with dentistry. These grants are available at all the dental and medical schools in the United Kingdom. The regulations can be obtained from the honorary secretary of the Odontological Section of the Royal Society of Medicine, 15, Cavendish-square, London, W.

THE SUCCESS OF FRENCH TEMPERANCE LEGISLATION.

IN the spring of 1906 we published a series of special articles on temperance legislation in France.[1] Both the French Government and the Paris municipality had resolved to carry into practice the resolutions adopted by the International Congresses of Hygiene in regard to alcoholism. The principle advocated was to combat the consumption of spirits by providing what is termed hygienic drinks at the lowest price possible. This includes all natural wines that have not been fortified or brandied, and pure beer, cider, or perry. On the other hand, spirits such as brandy, gin, whisky, or absinthe, could not be taxed too heavily. Therefore, while taxation on spirits was increased, almost every form of taxation, whether local or national, was removed from natural wines. The city of Paris suffered far and away the greatest financial loss, as it derived a large part of its income from town dues levied on wine and beer. The revenue from *octroi* duties throughout France on hygienic drinks was estimated at £3,466,440, of which the Parisians paid nearly two-thirds. At 10 fr. 62 c. per hectolitre the *octroi* duty on wine yielded £2,050,000 to the income of Paris. Now other taxes have had to be invented to replace this enormous sum, and we were subsequently able to buy wine at 2*d.* the litre in Paris. This wine, analysed in our laboratory, did not of course possess the bouquet, but it had the same composition of high-class and expensive clarets, though it only cost, at the retail price, 1½*d.* per English pint. It was cheaper than beer, and the argument is that when people can get good, wholesome, natural claret at a very low price, they will not drink any large amount of spirits, and therefore drunkenness will disappear. There is little or no drunkenness in wine-growing countries, where wine can be obtained for the asking. Still, the abolition of all taxation was considered a bold experiment. Last week, however, our Paris correspondent sent us the glad news that the venture has proved a great success. Dr. Jacques Bertillon presented 33 diagrams to the Academy of Moral and Political Sciences on Sept. 30th. These related to the consumption of spirits

[1] THE LANCET, March 10th (p. 709), 24th (p. 863), and April 7th (p. 994), 1906.

in as many large towns. Formerly the consumption of distilled spirits was almost the same in all these towns, and varied from 7 to 8 litres of absolute alcohol per head per annum. In the rural districts it was 2·84 litres. To-day, however, with wine so much cheaper, the consumption of spirits has greatly decreased, and the larger the town the greater the reduction. Thus in towns of 4000 to 10,000 inhabitants the figure had fallen to 6 litres, but in towns with a population of over 90,000 the consumption of alcohol now only amounts to 4·23 litres per head. This is a reduction that in some cases must be equal to close upon 50 per cent. and for the larger towns always exceeds 40 per cent. Nor is this an experiment made on a small scale with a group of people, a town or district. It has been carried on now for five or six years by a great nation on a population of 40,000,000 people, descended from different races, living in different climates and according to a great variety of local customs. It is rare, indeed, that such a wholesale experiment can be made, nor do we often obtain such encouraging results. With the quick and easy means of transit that exist there is no reason why we should not have in England claret as good and as cheap as that obtained in the northern non-wine-growing parts of France. The distance may be a little longer, but transit by sea is cheaper than by rail. This year wine is very dear, about 4½*d.* to 5*d.* a litre; but this has been an altogether disastrous and exceptional year. As a rule, excellent new and natural wine can be bought at the vineyard for about 2*d.* the litre.

WE regret to learn the death of Dr. W. R. Huggard, the well-known physician and British Consul at Davos.

Public Health.

ANNUAL REPORTS OF MEDICAL OFFICERS OF HEALTH FOR 1910.

City of Glasgow.—Dr. A. K. Chalmers includes in his report an instructive chapter on isolation hospitals, with special reference to their use for whooping-cough and measles. The mortality from both these diseases in Glasgow has long been persistently high, as the following figures show:—

Death-rates per 100,000 of Population in Glasgow and the Rest of Scotland Respectively.

	1855-64.	1865-74.	1875-84.	1885-94.	1895-04.	1905-8.
Whooping-cough.						
Glasgow	164	136	133	106	86	76
Rest of Scotland ...	54	49	52	49	42	36
Measles.						
Glasgow	89	85	63	77	64	56
Rest of Scotland ...	36	31	28	39	34	27

This excessive mortality is also brought out when the Glasgow rates are contrasted with those of certain English cities, which are fairly comparable in point of population and industrial pursuits. During the ten years 1898–1907 the average death-rates from whooping-cough in Liverpool, Manchester, and Birmingham were respectively 48, 44, and 44, against 80 in Glasgow, and from measles 49, 61, and 41, against 57 in Glasgow. Both diseases tend towards death through lung complications, and a marked difference in the temperature of the winter months might be thought to afford an explanation. But the mean temperature from October to March in Liverpool is 41·7°, in Manchester 43·5°, and in Birmingham 42·9°, against 43·0° in Glasgow. Nor will the presence of a large proportion of children at susceptible ages explain the greater prevalence of these diseases in Glasgow, for the birth-rate in Liverpool in the period in question was greater by 2 per 1000, while that in Manchester and Birmingham was practically identical with Glasgow. In Dr. Chalmers's view the important point in which Glasgow in this matter differs from these English cities is its custom of housing in flatted tenements, which affords greatly increased opportunities of infection from both diseases. It is noteworthy that there is no similar contrast in the relative incidence of enteric fever, scarlet fever, or diphtheria. The latter disease, for the same period, produced a death-rate of 15 per 100,000 in Glasgow, against 25, 18, and 21 in Liverpool, Manchester, and Birmingham. In Glasgow it has for many years been the practice to isolate a substantial portion of the known cases of whooping-cough and measles in the city hospitals. The proportion of cases isolated has remained fairly constant during the last 20 years at some 11 to 12 per cent. of the total known cases of measles, and from 19 to 28 per cent. of the total known cases of whooping-cough. A much larger number of total cases has, however, come under supervision in recent years, and the actual numbers isolated have been correspondingly higher. In 1906–09, for whooping-cough and measles respectively, the average annual total of cases registered was 3644 and 11,501, and the corresponding number of cases treated in hospital was 894 and 1355. In considering the advantages which the hospital isolation may have secured, Dr. Chalmers lays stress on the consideration that although the actual mortality rates from whooping-cough and measles are greater in Glasgow than in the rest of Scotland, the rate at which the mortality has been reduced during the past 50 years has been much more rapid in Glasgow in the case of whooping-cough, and somewhat more rapid also in the case of measles. He also points to the fact that in the cases of both diseases the hospital treatment materially lessens the severity and obviates the danger of sequelæ which, if untreated, may permanently impair the health or physical condition of some of those patients who survive the attack. It is clear that a strong case can be made out from the Glasgow records for the continuation and development of the local practice, and now that various other towns are making similar arrangements for isolation of measles and whooping-cough an additional body of evidence bearing on its utility should be available before long. The use to which the Glasgow city hospitals are now put differs greatly from that of past years. Before 1875 the whole hospital administration was dominated by the demand for the admission of typhus fever, which in some years was the cause of 9 out of every 10 admissions. Before 1900 the demand for accommodation for diphtheria was almost negligible, whereas this disease now furnishes from 12 to 17 per cent. of the total admissions. The proportion of the different diseases exercises an important effect on the nature of the accommodation required. When isolation of whooping-cough and measles cases is principally in question provision should be made for large numbers of convalescents in proportion to the acute cases, and should consist mainly of suitable dormitories, nurseries, and playrooms rather than of hospital wards in the ordinary sense. Some 1600 beds are now available at the city hospitals for all infectious diseases apart from small-pox, but Dr. Chalmers points out that this number needs to be increased if provision is to be made on as large a scale as that now available in London, Edinburgh, and Liverpool. A still more pressing need is the erection of a suitable small-pox hospital on a site sufficiently remote from populous centres.

City of Wakefield.—In course of a well-balanced review of the considerations which a municipality should keep in mind when endeavouring to combat tuberculosis, Dr. T. Gibson lays stress, not only on the usual "housing" reforms, but also on the great value of properly laid out open spaces. Whether the application of the Housing and Town Planning Act will secure such spaces on the outskirts, as the city extends, will be seen in a few years, but at the present time this need is very great in or close to the central and more congested areas. Though the inhabitants of Wakefield have easy access to the country, hundreds of people, especially mothers and young children, seldom wander far from their pent-up habitations and dreary surroundings. Dr. Gibson pleads also for old folks who cannot travel far from their doorsteps. In many parts of the town the necessary vacant spaces exist, and the opportunity should be utilised before they pass into the hands of the builder. In course of the medical inspection of school children, he found in 1909 that 95 out of 1649 (5·7 per cent.) and in 1910 82 out of 1900 (4·3 per cent.) presented some abnormality of the heart, and considers that in some at least of these cases it is specially important that advice as to choice of occupation should be given before the child leaves school. The moorland water from which the public supply of Wakefield

is obtained continues to be treated by filtration and made alkaline by the addition of lime, with results which are stated to be satisfactory as regards purity and ability to act on lead. The samples taken under the Sale of Food and Drugs Acts included 16 prescriptions, of which as many as four contained either an excess or a deficiency of the ingredients prescribed.

Urban District of Beckenham.—Dr. J. M. Clements comments upon the prevalence last year in Beckenham of diphtheria of a mild type, the case mortality being only 3·2 per cent. It would seem that clinically many of the notified cases have merely consisted of trivial sore-throats, which have been pronounced to be diphtheria as a result of bacteriological examination of swabs The occurrence of nine cases of diphtheria in the Alexandra school in June and July led to the examination of swabs from the throats of 395 children, in 7 of which diphtheria bacilli were found. It was noteworthy that neither the diphtheria cases nor the carriers were limited to one department or to any particular class, but were scattered irregularly throughout the school. The carriers were excluded until negative results were obtained, and no further spread occurred. The arrangements in this district under the diphtheria antitoxin order of the Local Government Board include supply of antitoxin free to local medical practitioners for use in cases of patients and contacts amongst the poorer classes, and the payment to such practitioners of 2*s.* 6*d.* for each patient and contact treated. The district council decided during the year to allow an additional private slaughter-house in Beckenham, but the local residents seem to have prevented its use. Dr. Clements states that the food sold throughout the district reaches a very high standard of purity. It would be useful for future reports to give supplementary information concerning the nature of the foods to which attention has been given during the year, and the particular forms of adulteration or misdescription which the officers concerned have had in view in arranging for the collection and examination of samples.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 77 of the largest English towns, having an estimated population of 16,157,797 persons in the middle of this year, 7557 births and 4707 deaths were registered during the week ending Oct. 7th. The annual rate of mortality in these towns, which had steadily decreased from 21·2 to 15·5 in the six preceding weeks, further declined to 15·2 per 1000 in the week under notice, and was 1·4 per 1000 below the mean annual rate recorded during the third quarter of the present year. In London the death-rate last week was equal to 15·0 per 1000, while the recorded rates in the other large towns ranged from 6·4 in Devonport, 8·3 in King's Norton, and 8·7 in Willesden, to in Burton-on-Trent, and in Coventry to 21·2 in Oldham and in Barrow-in-Furness, 21·6 in Bootle and in Wigan, and 23·9 in Tynemouth. The 4707 deaths from all causes in the 77 towns last week were 97 less than the number returned in the previous week, and included 802 which were referred to the principal epidemic diseases, against numbers decreasing from 2900 to 1056 in the six preceding weeks. Of these 802 deaths, 628 resulted from infantile diarrhœa, 55 from whooping-cough, 46 from diphtheria, 37 from enteric fever, 18 from measles, and 18 from scarlet fever, but not one from small-pox. The mean annual death-rate from these epidemic diseases last week was equal to 2·6 per 1000 against 5·0 and 3·4 in the two preceding weeks. The deaths of infants under 2 years of age attributed to diarrhœal diseases, which had steadily decreased from 2714 to 886 in the six preceding weeks, further declined last week to 628, and caused the highest annual death-rates of 4·5 in Walsall, 5·0 in Warrington, 5·1 in Stoke-on-Trent, and 6·9 in Burnley. The deaths referred to whooping-cough, which had been 55, 61, and 51 in the three preceding weeks, rose to 55 last week, and included 11 in London and its suburban districts, 6 in Leeds, 5 in Derby, 4 in Birmingham, and 4 in Leicester. The fatal cases of diphtheria, which had increased from 27 to 46 in the three preceding weeks, were again 46 last week; 14 deaths were recorded in London and its suburban districts, and 3 each in Portsmouth, Stoke-on-Trent, Liverpool, Preston, and Leeds. The deaths attributed to enteric fever, which had decreased from 41 to 35 in the three preceding weeks, were 37 last week, and comprised 12 in London and its suburban districts, 3 in Huddersfield, and 2 each in Grimsby, Liverpool, St. Helens, and Cardiff. The deaths referred to measles, which had declined from 59 to 19 in the seven preceding weeks, were 18 last week, and was the lowest number recorded in any week of the current year; 4 deaths occurred in London, 2 in Wolverhampton, and 2 in Manchester. The 18 fatal cases of scarlet fever were 3 in excess of the average recorded in the three preceding weeks, and comprised 4 in London, 3 in Stoke-on-Trent, and 2 each in Birmingham, Liverpool, Manchester, and Hull. The number of scarlet fever patients under treatment in the Metropolitan Asylums and in the London Fever Hospital, which had increased from 1327 to 1666 during the five preceding weeks, had further advanced to 1793 on Saturday last; 293 new cases of this disease were admitted to these hospitals during the week, against 264, 240, and 333 in the three preceding weeks. These hospitals also contained on Saturday last 973 cases of diphtheria, 218 of whooping-cough, 169 of enteric fever, and 87 of measles, but not one of small-pox. The 1301 deaths from all causes in London last week were 48 less than the number in the previous week, and included 172 which were referred to diseases of the respiratory system, against numbers steadily increasing from 73 to 149 in the five preceding weeks. The deaths attributed to different forms of violence in the 77 towns, which had declined from 171 to 134 in the four previous weeks, rose again to 156 last week, and 374 inquest cases were registered. The causes of 27, or 0·6 per cent., of the deaths registered in the 77 towns during the week under notice were not certified either by a registered medical practitioner or by a coroner after inquest. All the causes of death were duly certified last week in Leeds, Bristol, West Ham, Bradford, Newcastle-on-Tyne, Nottingham, Stoke-on-Trent, Salford, and in 52 other smaller towns. The 27 uncertified causes of death last week included 5 in Liverpool, 3 in Birmingham, and 2 each in Manchester, Sheffield, Hull, and Tynemouth.

HEALTH OF SCOTCH TOWNS.

In eight of the principal Scotch towns, having an estimated population of 1,710,291 persons in the middle of this year, 825 births and 490 deaths were registered during the week ending Oct. 7th. The annual rate of mortality in these towns, which had been 15·7, 16·7, and 15·2 per 1000 in the three preceding weeks, declined to 14·9 in the week under notice. During the 13 weeks of the third quarter of this year the annual death-rate in these towns averaged 15·2 per 1000, and was 1·4 per 1000 below the mean rate during the same period in the 77 large English towns. The annual death-rates in the Scotch towns last week ranged from 11·6 and 12·3 in Leith and in Paisley to 15·4 in Edinburgh and 19·0 in Dundee. The 490 deaths from all causes in the eight towns were 9 fewer than the number in the previous week, and included 60 which were referred to the principal epidemic diseases, against numbers declining from 134 to 78 in the five preceding weeks; of these 60 deaths, 33 resulted from diarrhœa, 11 from diphtheria, 8 from scarlet fever, 4 from measles, 3 from whooping-cough, and 1 from enteric fever, but not one from small-pox. The mean annual death-rate from these epidemic diseases in the eight towns last week was equal to 1·8 per 1000, and was 0·8 below the mean death-rate from the same diseases in the 77 large English towns. The deaths attributed to diarrhœal diseases, which had steadily fallen from 113 to 52 in the five preceding weeks, further declined to 33 last week and included 26 of infants under two years of age; 16 deaths were recorded in Glasgow, 8 in Dundee, and 4 in Aberdeen. The deaths referred to diphtheria, which had been 10, 5, and 13 in the three preceding weeks, were 11 last week, and included 4 in Glasgow and 2 in Perth. The fatal cases of scarlet fever, which had been 2, 5, and 3 in the three previous weeks, rose last week to 8, and comprised 4 in Glasgow, 2 in Edinburgh, and 2 in Aberdeen. The 4 deaths attributed to measles were 3 in excess of the number in the previous week, and included 2 in Glasgow. The deaths referred to whooping-cough, which had been 12 and 8 in the two preceding weeks.

declined to 3 last week, and comprised 2 in Glasgow and 1 in Aberdeen. The fatal case of enteric fever was registered in Glasgow. The deaths referred to diseases of the respiratory system, which had increased from 41 to 62 in the three preceding weeks, further rose last week to 78, and were 6 above the number in the corresponding week of last year. Of the 490 deaths from all causes in the eight towns last week, 170, or 35 per cent., were recorded in public institutions, and 28 deaths were attributed to different forms of violence. The causes of 10, or 2·0 per cent., of the deaths in the eight towns last week were not specified or not certified; in the 77 English towns the proportion of uncertified causes last week did not exceed 0·6 per cent.

HEALTH OF IRISH TOWNS.

In the 22 town districts of Ireland, having an estimated population of 1,149,495 persons in the middle of this year, 565 births and 431 deaths were registered during the week ending Oct. 7th. The annual rate of mortality in these towns, which had been 20·4 and 18·0 in the two preceding weeks, rose to 19·6 per 1000 in the week under notice. During the 13 weeks of the third quarter of this year the annual death-rate in these Irish towns averaged 18·3 per 1000; in the 77 English towns during the same period the mean annual death-rate was equal to 16·6, whilst in the eight Scotch towns it did not exceed 15·2 per 1000. The annual death-rate last week was equal to 22·1 in Dublin (against 15·0 in London), 17·3 in Belfast, 25·2 in Cork, 7·7 in Londonderry, 20·4 in Limerick, and 19·0 in Waterford; whilst in the 16 smallest of these Irish towns the mean annual death-rate did not exceed 19·0 per 1000. The 431 deaths from all causes in the 22 Irish towns were 35 in excess of the number returned in the previous week, and included 81 which were referred to the principal epidemic diseases, against 122 and 95 in the two preceding weeks; of these 81 deaths, 71 resulted from diarrhœal diseases, 4 from enteric fever, 3 from scarlet fever, 2 from measles, and 1 from whooping-cough, but not one from small-pox or from diphtheria. These 81 deaths from the principal epidemic diseases were equal to an annual death-rate of 3·7 per 1000. The mean rate from the same diseases in the 77 English towns last week was equal to 2·6, while in the eight Scotch towns it did not exceed 1·8 per 1000. The deaths attributed to diarrhœal diseases, which had decreased from 121 to 81 in the three preceding weeks, further declined to 71 last week, and included 66 of infants under two years of age; 33 deaths were recorded in Dublin, 18 in Belfast, and 5 in Cork. The 4 deaths attributed to enteric fever were 1 in excess of the average in the four preceding weeks, and comprised 2 in Dublin and 2 in Belfast. The 3 fatal cases of scarlet fever were equal to the average in the four preceding weeks, and were registered in Dublin, Belfast, and Ballymena respectively. The 2 deaths referred to measles occurred in Newtownards, and the fatal case of whooping-cough in Belfast. The deaths referred to diseases of the respiratory system, which had averaged 43 in the four preceding weeks, rose to 64 last week. Of the 431 deaths from all causes in the Irish towns last week, 139, or 32 per cent., were recorded in public institutions, and 8 deaths were attributed to different forms of violence. The causes of 10, or 2·3 per cent., of the deaths registered in the 22 towns last week were not certified either by a registered medical practitioner or by a coroner after inquest; the proportion of uncertified causes of death in the week under notice did not exceed 0·6 per cent. in the 77 large English towns, but equalled 2·0 per cent. in the eight Scotch towns.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments have been notified:—Fleet-Surgeons: T. T. Jeans to the *Vivid*, additional, for the *Dartmouth*: T. C. Meikle to the *Dryad*; and J. A. L. Campbell, to the *Carnarvon*. Staff-Surgeon: G. C. C. Rose to the *President*, for the *Maine*. Surgeons: J. McCutcheon to Chatham Hospital as anæsthetist and radiographer on conclusion of course; R. Connell to the *President*, additional, for three months' special course of study at West London Hospital, and to Plymouth Hospital as anæsthetist and radiographer on conclusion of course; A. B. Marsh to Haslar Hospital; and H. E. Perkins to the *Hibernia*.

2ND LIFE GUARDS.

Captain Evelyn John Hansler Luxmoore, from the Royal Army Medical Corps, to be Surgeon Captain (dated Sept. 27th, 1911).

ARMY MEDICAL SERVICE.

Colonel Alfred Peterkin is placed on retired pay (dated Oct. 2nd, 1911).

Lieutenant-Colonel Herbert J. Barratt, from the Royal Army Medical Corps, to be Colonel, vice A. Peterkin (dated Oct. 2nd, 1911).

ROYAL ARMY MEDICAL CORPS.

Major Herbert I. Pocock to be Lieutenant-Colonel, vice H. J. Barratt, promoted (dated Oct. 2nd, 1911). Major Edgar McK. Williams retires on retired pay (dated Oct. 4th, 1911). Major Arthur O. B. Wroughton, from the Half-pay List, is restored to the establishment (dated Sept. 20th, 1911). Captain Ernest Blake Knox to be Major.

Lieutenant-Colonel W. T. Swan, commanding the Fourth and Fifth Companies of the Royal Army Medical Corps and in charge of the Royal Victoria Hospital at Netley, has been selected for the higher rate of pay under Article 317 of the Royal Warrant. Lieutenant-Colonel S. Hickson has taken over medical charge of the Cambridge Hospital at Aldershot. Lieutenant Colonel S. C. Chilson, commanding the Station Hospital at Bareilly, has arrived home on leave of absence. Lieutenant-Colonel J. Donaldson, in medical charge of the Infectious Diseases Hospital at Aldershot, has been detailed by the War Office for a tour of service in South Africa and will embark during the coming trooping season. Lieutenant-Colonel W. H. Starr, on return from a tour service in Burma, has taken up duty at the Military Hospital, Lichfield. Major A. O. B. Wroughton, on return from leave of absence on medical certificate on half-pay, has been appointed to the Eastern Command for duty. Major H. O. B. Browne Mason has been appointed Specialist in Dermatology and Venereal Diseases to the Sixth (Poona) Division by the Principal Medical Officer of His Majesty's Forces in India. Major O. L. Robinson has been transferred from Kirkee to the Station Hospital at Poona for general duty. Major F. J. Brackenridge, specialist in state medicine, has been appointed to the medical charge of troops at Oxford. Major S. A. Archer has arrived home on leave of absence from Jullundur. Captain G. Baillie has joined the London District for duty on return from the West Coast of Africa. Captain E. Scott-Worthington, M.V.O., has been struck off the strength of the London District and has taken up duty as medical officer on the staff of H.R.H. the Duke of Connaught, Governor-General of Canada. Captain F. Forrest, stationed at Bangalore, has been granted eight months' leave of absence home from India. Captain F. J. Stuart has been transferred from the Eighth (Lucknow) Division to the Seventh (Meerut) Division as Specialist in Dermatology and Venereal Diseases. An exchange of position on the roster for service abroad has been sanctioned by the War Office between Captain A. F. Weston and Captain A. H. McN. Mitchell. Captain P. Davidson, D.S.O., has been appointed Company Officer at the Royal Army Medical Corps Depôt, Aldershot. Captain E. W. Powell and Captain A. H. Safford, specialists in the prevention of disease, have resumed charge of the Brigade Bacteriological Research Laboratories at Aden and Fyzabad respectively. Captain F. A. McCammon has been granted one month's extension of his leave of absence home from India. Captain E. V. Aylen has been transferred from the First (Peshawar) Division to the Second (Rawal Pindi) Division, and appointed Specialist in Dermatology and Venereal Diseases in succession to Captain D. de C. O'Grady, who has taken up duty at Peshawar in the same capacity. Captain D. S. Skelton and Captain J. E. Powell have been posted to the Northern Command for duty. Captain F. M. M. Ommanney, company officer of the 9th Company Royal Army Medical Corps, Colchester District, has been granted leave of absence preparatory to joining the Royal Army Medical College, London, for the promotion course for Captains commencing on Nov. 1st next. Captain H. B. Connell, on the termination of leave granted for duty on the

West Coast of Africa, has been appointed to the Irish Command and posted for duty at the Royal Infirmary, Phœnix Park, Dublin. Captain C. R. Sylvester Bradley has been appointed a Specialist in Physical Training and posted for duty to the Military Hospital at Cosham on completion of the course for promotion held recently at the Royal Army Medical College, London. Lieutenant F. W. M. Cunningham, from the Curragh, has taken up duty at Donard Camp. Lieutenant M. J. Williamson, from medical charge of the 18th Hussars at Hamilton Camp, Salisbury Plain, has been posted to the Military Hospital at Tidworth. Lieutenant E. C. Stoney has joined at Colchester on the return of Major C. W. Allport to the medical charge of the Military Hospital at Great Yarmouth.

INDIAN MEDICAL SERVICE.

Lieutenant-Colonel C. N. C. Wimberley has been selected by the Commander-in-Chief in India for appointment as Staff Officer of Medical Mobilisation Stores to the Sixth (Poona) Division, in succession to Major T. A. Granger, whose tenure of the appointment has expired. Lieutenant-Colonel Lloyd-Jones has taken up duty as Assay Master in the Bombay Mint in succession to Lieutenant-Colonel A. Milne, who has retired from the service. Lieutenant Colonel E W. Hore, second class agency surgeon, Bengal Presidency, has been granted six months' leave of absence home from India. Lieutenant-Colonel A. Street, on expiration of his leave of absence, has been permitted by His Majesty's Secretary of State to return to India for duty. Major R. F. Baird, from Mainpuri, has been selected to succeed Major R. G. Turner as Civil Surgeon at Gonda during the latter's absence on leave. Major W. Lethbridge, in medical charge of the Mewar Bhil Corps, has been granted one month's leave of absence. Major W. H. Kenrick, on special duty in connexion with the investigation of malarial fevers in India, has been attached to the office of the Sanitary Commissioner of the Central Provinces. Major J. Penny has been granted six months' extension of leave on medical certificate. The services of Captain G. Holroyd have been placed at the disposal of the Government of Bengal as a temporary measure for employment in the Jail Department of the Bengal Presidency. Captain A. D. White, officiating resident surgeon at the Medical College, Calcutta, has been selected for appointment as Second Resident Surgeon in the Presidency General Hospital, Calcutta, during the absence on deputation of Captain J. Masson. Captain H. E J. Batty has taken up duty as Civil Surgeon in the Malakand District, relieving Captain C. H. Cross. Captain A. Cameron has been appointed District Plague Medical Officer at Delhi. Captain Lee Abott has relinquished charge of the Ferozopore Central Jail. The services of Captain M. F. Reaney have been placed permanently at the disposal of the Honourable the Chief Commissioner of the Central Provinces. Captain R. B. Nicholson has been selected for appointment as Medical Officer to the 36th Jacob's Horse. Captain E. J. C. MacDonald has taken up duty as District Plague Medical Officer at Gurgaon.

TERRITORIAL FORCE.

Honourable Artillery Company.

Surgeon-Major Edward H. Myddelton-Gavey resigns his commission, retires into the Veteran Company, and is granted permission to retain his rank and to wear the prescribed uniform (dated Oct. 4th, 1911).

Yeomanry.

Royal East Kent (The Duke of Connaught's Own Mounted Rifles) Yeomanry: Surgeon-Lieutenant Campbell T. Fox to be Surgeon-Captain (dated August 26th, 1911).

Royal Engineers.

2nd London Divisional Engineers, Royal Engineers: Surgeon-Major William H. Bourke resigns his commission and is granted permission to retain his rank and to wear the prescribed uniform (dated Oct. 4th, 1911).

Infantry.

4th Battalion, The Welsh Regiment: Surgeon-Lieutenant William R E. Williams to be Surgeon-Captain (dated July 30th, 1911).

4th Battalion, The Oxfordshire and Buckinghamshire Light Infantry: Surgeon-Major Julius O. Sankey retires, under the conditions of Paragraph 116 of the Territorial Force Regulations, and is granted permission to retain his rank and to wear the prescribed uniform (dated Oct. 7th, 1911).

Royal Army Medical Corps.

1st Home Counties Field Ambulance, Royal Army Medical Corps: Lieutenant Sidney W. Milner resigns his commission (dated Oct. 4th, 1911).

1st London (City of London) Field Ambulance, Royal Army Medical Corps: Lieutenant Arthur Donald John Bedward Williams, from the List of Officers attached to Units other than Medical Units, to be Lieutenant (dated Sept. 7th, 1911).

2nd Eastern General Hospital, Royal Army Medical Corps: Hugh Nethersole Fletcher to be Captain (dated Oct. 4th, 1911). Frederick Arundel Stewart Hutchinson to be Captain (dated Oct. 4th, 1911).

1st Western General Hospital, Royal Army Medical Corps: Captain Robert C. Dun resigns his commission (dated Oct. 7th, 1911).

For Attachment to Units other than Medical Units.—Horace Guy Lankester Haynes (late Cadet Sergeant, Cambridge University Contingent, Senior Division, Officers Training Corps) to be Lieutenant (dated June 18th, 1911). Robert Craig Dun (late Captain, 1st Western General Hospital, Royal Army Medical Corps) to be Lieutenant (dated Oct. 7th, 1911).

Attached to Units other than Medical Units.—Captain David Walker to be Major (dated July 27th, 1911). Supernumerary Lieutenant David A. Hughes to be Captain (to remain supernumerary) (dated July 28th, 1911) Captain Herbert Meggitt resigns his commission (dated Oct. 7th, 1911). Captain Alexander H. Pirie resigns his commission (dated Oct. 7th, 1911). Captain John Forbes resigns his commission (dated Oct. 7th, 1911). Captain Charles Ernest Goddard, from the 1st London (City of London) Sanitary Company, Royal Army Medical Corps, to be Major (dated July 3rd, 1911).

The undermentioned officers resign their commissions (dated Oct. 4th, 1911):—Captain George R. F. Stilwell. Lieutenant Herbert P. S. Devitt.

EXAMINATION FOR COMMISSIONS IN THE ROYAL NAVY MEDICAL SERVICE.

The next examination of candidates for Commissions in the Royal Navy Medical Service will be held at Examination Hall, Thames Embankment, on Nov. 20th next and following days, when 15 Commissions will be offered. The regulations for entry and the form to be filled up by candidates will be supplied on application to the Medical Director-General, Admiralty, S.W.

JOURNAL OF THE ROYAL ARMY MEDICAL CORPS.

A short article in the October issue of the above journal which will be read with much interest reviews the Manuals of Physical Training in Germany, Austria, and Great Britain. The author, Captain J. A. Black, compares the methods of physical training in use in the armies of the different countries mentioned, and points out the direction in which our own system of physical training might be amplified. Incidentally Captain Black expresses the opinion that swimming should be taught in our army, and he appears to think that the addition of a swimming bath to every gymnasium is a counsel of perfection which is not likely to be realised. It is difficult, however, to imagine on what grounds the authorities could refuse to sanction so important an addition to the means for physical training, and for securing cleanliness, in the army. Captain Black's remarks on "obstacle training" deserve careful attention, as they not only show that training in the gymnasium in this connexion may be for all practical purposes useless, but also point out how the exercises if they are to be effective should be carried out. Lieutenant-Colonel C. H. Melville adds a note dealing with a new issue of *Turnvorschrift für die Infanterie* (Manual of Physical Training for Infantry), at the conclusion of which he says: "It is interesting to note that we who as a nation have always prided ourselves on getting our physical training out of our games should now be turning to formal exercises for that purpose, while the leading military nation on the continent is showing a distinctly opposite trend." The report on "An Experimental March to Investigate the Amount of Food Required by Men on Active Service" is continued.

Correspondence.

"Audi alteram partem."

THE NATIONAL INSURANCE BILL.

To the Editor of THE LANCET.

SIR,—IN the *Daily News* of Oct. 3rd Dr. Macnamara was reported as having said to the Old Kent-road Brotherhood that he had received a letter from Mr. Lloyd George on the Insurance Bill, in which the Chancellor of the Exchequer stated: "You may tell your friends in London that the Government means to press the Insurance Bill through during the autumn session. There is no idea of abandoning any part of it. We shall stand or fall by it as a whole. The suggestion that we should at this stage divide the benefits—carry a third of them on to the Statute Book this session and postpone the rest—is a particularly fatuous one. No one who knows anything about the Bill or its history could ever have made such a proposal. Parliament has already after weeks of discussion settled the benefits. When we meet we shall proceed to a consideration of the machinery of distribution and control." If, therefore, the Bill is to be thrust through in its present form, as the Chancellor of the Exchequer seems to imply, it is now necessary to survey the position of the measure in so far as it affects the medical profession, and the degree in which the demands of that profession have been met.

These demands were definitely formulated in the six points which were laid down in the circular of June 3rd of the British Medical Association submitted to Members of Parliament by numerous deputations. The six points demanded were:—

1. An income limit of £2 a week for those entitled to medical benefit.
2. Free choice of doctor by patient, subject to consent of doctor to act.
3. Medical and maternity benefits to be administered by Local Health Committees and not by Friendly Societies.
4. The method of remuneration of medical practitioners adopted by each Local Health Committee to be according to the preference of the majority of the medical profession of the district of that committee.
5. Medical remuneration to be what the profession considers adequate, having due regard to the duties to be performed and other conditions of service.
6. Adequate medical representation among the Insurance Commissioners, in the Central Advisory Committee, and in the Local Health Committees, and statutory recognition of a Local Medical Committee representative of the profession in the district of each Health Committee.

So far as the Bill at present stands, though in many cases the amendments adopted in committee are conflicting, very little real concession has been granted.

1. The only income limit in the Bill is that of the income tax—namely, an income of £160 per annum—although Local Health Committees are empowered at their discretion to fix an income limit, and persons whose income exceeds this limit are to make their own arrangements for medical attendance and treatment. The £2 per week income limit suggested by the British Medical Association was rejected, and all that has been secured is a limit which may vary under different local conditions.

2. The principle of the free choice of doctor, "subject to consent of doctor to act," has been conceded, but unless the wording of Clause 14, Section 1, Subsection 2 (d), be amended, the doctor will have no option of refusal. The passage runs as follows: (Local Health Committees are to adopt such system as will secure) "the distribution amongst and, so far as practicable, under arrangements made by the several practitioners whose names are on the lists of the insured persons who, after due notice, have failed to make any selection, or who have been refused by the practitioner whom they have selected." The importance of this provision cannot be over-rated, and must in any case afford ground for constant disputes. The reasons for rejection by practitioners are obvious—age, chronic ill-health, residence at an extreme distance, any of these form a valid ground for rejection of attendance on the ordinary terms. Yet I can find no instructions to the local committees to allow any increase of fees for attendance on such persons, and there is a just fear that practitioners will find it impossible to refuse such cases, under the present wording of the provision. The words, "so far as practicable," are obviously capable of meaning nothing at all.

3. The removal of the control of medical benefits from the hands of Friendly Societies has been, in effect, very partially allowed, although the principle was carried by a large majority in Parliament. Not to mention the large representation of the Friendly Societies on the Local Health Committees, the Bill as it now stands contains a section of Clause 14—namely, Section 4, which provides that any system or organisation providing medical attendance and treatment and existing at the time of the passing of this Act if approved by the Local Health Committee and the Insurance Commissioners may be maintained. This section obviously covers the case of all existing medical clubs and associations. Thus it would seem that the Friendly Societies may still retain control of their medical benefits and their medical officers, and therefore the principle of the removal of control is largely nullified.

4 and 5. These two points dealing with the method and amount of remuneration are not considered in the Bill. If we may judge from the example of the Vaccination and Poor-law Acts the matter will be left in the hands of the Local Health Committees, though without the legal minimum of payment which at present exists in the case of vaccination; and it is quite evident that not much is to be expected in the way of support from the Insurance Commissioners when any demand for an increase in pay is made.

6. This point, dealing with adequate medical representation, has been nominally granted, though what the Government's idea of the meaning of the word "adequate" is remains to be seen. At present we only know that the medical profession will be represented on administrative bodies.

From this survey of the position as it is at present it is plain that the demands of the British Medical Association have been granted only to a very limited extent. Those points which are dealt with in the Bill—namely, points 1, 2, 3, and 6—are treated in such a way that what is given with the one hand is largely taken away with the other. The remaining points—namely, 4 and 5—dealing with the method and amount of remuneration, are left on one side, the Chancellor of the Exchequer's probable intention being to remit the matter to local administrative bodies. In this way the medical profession may be fought in scattered detachments, and it will be necessary for the medical profession (if the rank and file are to preserve the power of making a competent livelihood) to offer an obstinate resistance. What may be called the staff organisation of the profession has, I consider, already been out-generalled in the engagements which have at present taken place. It is now necessary for the units composing the medical forces—namely, the various local bodies of medical men—to see that in the probable forthcoming fights with local administrative bodies a strenuous resistance is offered to those whose wish it is to exploit the labours of the medical profession.

I am, Sir, yours faithfully,

Westerham, Kent, Oct. 6th, 1911. ARTHUR MAUDE.

To the Editor of THE LANCET.

SIR,—Will you permit me to make a short reply to the letters you have published criticising my suggestion as to a State Medical Service? I gather from these letters that there are only three alternatives to control by the State—1. That the profession should be controlled by Friendly Societies, either themselves or under the name of Health Committees, and should be left in each separate district to bargain with them as to remuneration. 2. That with the control of Health Committees fees should be paid for each separate attendance on persons insured. 3. That the medical benefits under the Bill should be dropped, leaving the people without any medical attendance except as at present in force.

1. I have pointed out the disadvantages of the question of remuneration being left open, and I purposely did not allude to the proposed medical representation on the Health Committees, as I thought it was clear to everyone that one or two medical men on a committee composed of representatives of Friendly Societies, local boards, and insured persons could have no weight, and in fact would not be listened to on a question of medical remuneration. 2. The suggestion of payment by fee for each attendance is a delightful dream, but purely Utopian and out of the range of practical politics, as it would land the Insurance Fund in bankruptcy in the

first year. 3 The proposal to drop the medical benefits is to my mind unthinkable; the great feature of this magnificent measure is the giving of full and sufficient medical service to people who have never been able to afford it, so that the health and therefore well-being of the nation shall be immensely increased.

I cannot see any objection to control by a department of the State which would consider the representations of medical men, Friendly Societies, and all others interested, but would be responsible for the appointment of medical officers and for an efficient and up-to-date medical service; nor can I see any chance of such a service degenerating into a glorified version of the present Poor-law Medical Service, which is condemned on every side and has but a short lease of life. I am, Sir, yours faithfully,

South Hampstead, N.W., Oct. 7th, 1911. ALBERT BENTHALL.

THE NOMENCLATURE OF SPINAL DEFORMITIES.

To the Editor of THE LANCET.

SIR,—It appeared to me that in his article of Sept. 2nd Mr. R. Timberg was particularly careful in his terminology when dealing with lateral curvature of the spine, and herein my impression differs from that of Mr. Paul B. Roth. I do not agree with Mr. Timberg's explanation of the cause of rotation of the vertebræ in lateral curvature, but I am very certain that he recognises the three distinct stages through which a lateral curvature passes, and a consideration of these three stages will do much to bring about that unity of expression which his critic advocates.

The first stage is that in which the spine assumes a lateral curve without any rotation. Experiments upon the cadaver have shown me the all-important influence of the presence of the ribs in the dorsal region upon the commencement of rotation, and that this first stage is limited by the amount of play in the costo-vertebral articulations. When this play has been taken up on the convex side of the curve the tubercles of the ribs on that side become firmly applied to the tips of the transverse processes of the vertebræ, with the result that further lateral movement of the posterior part of the column is resisted and a rotation is initiated which the forces bending the column outwards are bound to increase. This first stage must not be called skoliosis—there is no rotation or "twisting," and it is correctly alluded to by Mr. Timberg as "lateral deviation."

The second stage is that in which rotation and further side movement of the spine are accommodated by the general mobility of the thorax derived from the elasticity of the ribs and of their cartilages. The third stage commences when the extent of the said elasticity of the thoracic cage is reached, so that the ribs yield to prolonged and increasing pressure, and permanent bending, leading to fixation of the deformity, takes place. Both second and third stages are correctly termed skoliosis.

Bearing in mind these three stages, Mr. Timberg's meaning in the two following sentences is surely very clear: "At first it is merely a lateral deviation, but an added rotation of the interested vertebræ will soon convert it to a more or less fixed scoliosis." "The simple lateral deviation is generally easily amenable to treatment; and a curve in the second degree of severity—i.e., a true scoliosis, but not yet fixed—is, in favourable circumstances, capable of perfect recovery."

These three stages in the progress of a lateral curvature constitute the anatomical foundation of a classification of cases which may be set forth as follows:—Grade I.: Those in which the spine may be straightened out to normal by posture. Grade II.: Those in which the spine may be straightened out to some extent by posture, but in which some measure of the deformity still remains owing to bony displacement being maintained by muscular and ligamentous shortening. Grade III.: Those in which the deformity is so confirmed that radical changes in the shape of the ribs, and inferentially of the vertebræ, are palpable, and in which the alteration produced by posture is inconsiderable. These three grades pass imperceptibly one into the other, and the borderland between Grades II. and III. presents some cases occurring in patients of the "rigid" type, of which a correct estimate cannot be formed until the thoracic cage has been rendered mobile by means of suitable exercises. But, with experience in examination, there is little difficulty in relegating any one case to its proper grade; the distinction is about as definite as that between degrees of burn. Here, then, we have an example of a clear and rational way out of complex terminology, and I suggest that we follow the method adopted long ago by the Berlin school and classify our cases of lateral curvature as of Grade I., II., or III., as the case may be.—I am, Sir, yours faithfully,

J. S KELLETT SMITH.

Cavendish-place, W., Oct. 9th, 1911.

LIGATURE OF THE SPERMATIC ARTERY IN THE OPERATION FOR VARICOCELE.

To the Editor of THE LANCET.

SIR,—In an annotation on this subject in your last issue (Oct. 7th, pp. 1026-1027) you infer that Dr. E. Styles Potter by including in his ligature the spermatic artery as well as the veins is peculiar in his practice. This is not so. The great majority of surgeons like him do not trouble to exclude the artery from their ligature. To ligature the artery as well as the veins is the better practice; as by removing some veins only and not occluding the artery, a few veins alone are left to carry off the whole of the blood brought to the testicle by the spermatic and deferential arteries. Whilst if the spermatic artery is ligatured at the same time that the spermatic veins are removed there will be less work to do for the veins left behind as there will be less blood reaching and to be borne away from the testicle.

This balance between the entrance and exit of blood from the testicular area is upset by the operation for varicocele. But it is far less upset if the spermatic artery is ligatured with the veins than if it is left unoccluded. The clinical expression of the disturbance of this balance is the occurrence of œdema of the scrotum and hydrocele of the tunica vaginalis. On p. 279 of my "Male Diseases in General Practice" (Oxford Medical Publications) the results of the operation for varicocele are tabulated, and it will be noticed that hydroceles in some form were found in no less than 23 per cent. Thickening of the scrotal tissues was found in 50 per cent. of cases. Hence, it is obvious that the ordinary operation for varicocele with occlusion of the spermatic artery does disturb the "circulatory balance" of the testicular area. As a result of this knowledge, I now invariably whilst operating for varicocele draw the testicle into the wound and turn the tunica vaginalis inside out. This additional procedure—extroversion of the tunica vaginalis—has been most successful in lowering the percentage of the occurrence of hydrocele after varicocele operations.

You, Sir, state that Dr. Styles Potter designs to ligature the spermatic artery alone for varicocele. This has been done experimentally and with disastrous results to the physiological active tissues of the testis. Moreover, it produces venous engorgement of the testicular area by cutting off the main source of pressure, the arterial pressure, which drives the blood through the testicle and veins towards the heart. Hence ligature of the spermatic artery by itself is a far more disturbing procedure on the circulatory balance of the testicular area than the operation for varicocele as ordinarily practised, removal of part of the spermatic artery and many of the spermatic veins. In addition to this proceeding I would urge that extroversion of the tunica vaginalis be also done in every case. Stoppage of the blood-stream by atheroma inhibits what may be called the *vis a tergo* of the testicular circulation leading to venous engorgement, chronic inflammation, and, I believe, to the hydroceles of the men of, say, over 40. Atheroma of the spermatic arteries is the first stage of the involution of the testicles.

I am, Sir, yours faithfully,

Harley-street, W., Oct 7th, 1911. EDRED M. CORNER.

TOXIC EFFECT OF ASPIRIN.

To the Editor of THE LANCET.

SIR,—I would suggest to Dr. A. Brown that he try the effect of gr. v. of aspirin *in suspension* in the case in which a tablet of similar composition produced urticaria. I have not infrequently been told by patients that tablets of aspirin had caused fairly acute epigastric pain, but I have never had any similar complaints when the aspirin has been taken in suspension. The result of giving aspirin in suspension in

Dr. Brown's case would be of interest, not only in connexion with the toxicology of aspirin, but also in the more important and much-debated question—the etiology of urticaria.

I am, Sir, yours faithfully,

Brook-street, W., Oct. 9th, 1911. J. BRUNTON BLAIKIE.

NOTE ON TWO CASES OF TUMOUR OF THE PREFRONTAL LOBE IN CRIMINALS.

To the Editor of THE LANCET.

SIR,—Dr. W. C. Sullivan, under this title in THE LANCET of Oct. 7th, p. 1004, relates two cases of tumour of the prefrontal lobe. It would be interesting to know whether it was known if the patients were right- or left-handed, especially in the first case, in which a growth involved the left inferior frontal convolution without aphasic symptoms. In this latter case was any of the cortex left intact between the growth and the precentral sulcus?

I am, Sir, yours faithfully,

Cheltenham, Oct. 6th, 1911. A. E. TAIT, M.B. Edin.

THE INHERITANCE OF SYPHILIS.

To the Editor of THE LANCET.

SIRS,—On several occasions, and notably in the discussion on "Inherited Syphilis" before the Society for the Study of Disease in Children,[1] I have expressed the opinion that what we in England call congenital syphilis (hereditary syphilis of continental writers) was derived from the mother, and that there was no proof of direct paternal infection. Matzenauer in his exhaustive monograph, "Die Vererbung der Syphilis,"[2] has dealt with the matter in a most thorough manner. On the continent direct paternal infection is usually accepted as a matter of course, as a reference to text-books on syphilis will show. My object in again referring to the subject is to call attention to the opinion expressed by M. Jeanselme, a very careful observer, in a recent monograph on syphilis from the points of view of etiology and prophylaxis.[3] This is what he says: "En somme, dans l'immense majorité des cas, sinon dans tous, l'enfant tient la syphilis de sa mère." Such an opinion coming from a French expert is very important, for the paternal view is practically unchallenged in France. Dr. Carle of Lyons has also recently dealt critically with the subject of the direct paternal influence,[4] and relates an instructive instance of the ease with which an erroneous *paternal* conclusion may be arrived at. The matter is of interest as it must, to some extent, affect our views as to the length of time that should elapse between infection and marriage in the case of males. I do not propose to enter here into the various aspects of the subject, but would merely point out that in many cases the interval has been a much shorter one than that usually recommended by the medical man, patients (males) taking the law into their own hands without any untoward results ensuing, either as regards the female or her progeny.

I am, Sir, yours faithfully,

London, W., Oct. th, 1911. GEORGE PERNET, M.D.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

Opening of the Medical Session: the Scope of Anatomy.

Professor G. Elliot Smith on Oct. 2nd gave the inaugural address at the opening of the medical session. The title of the lecture, "The Present Position and Scope of Anatomy," was sufficiently wide and comprehensive, and enabled the lecturer to deal in an attractive manner with the prospects of the science as a subject for the instruction of medical students. Certain reforms in the teaching of anatomy—"an ancient and royal study, with a very long tradition behind it"—were suggested. Ancient though its lineage might be, it could only be brought into a proper relation with other subjects of the medical curriculum by throwing off the trammels of its past. In many respects present-day methods of teaching anatomy were appropriate only to the surgery of a hundred years ago or more. It was necessary to break away from tradition and to teach students the anatomy which would be useful to them. According to Professor Elliot Smith there are still far too many lectures, from which the student can learn little more than from an efficient text-book. Of text-books in anatomy there are enough and to spare. Lectures on the bones left the student with nothing but disgust for the whole subject of anatomy, his initial "considerable enthusiasm" disappearing very rapidly. The sort of knowledge which is needed in the student of anatomy is a complete grasp of locality—the formation of a visual picture of anatomical structures. The student should be guided to do his practical work thoroughly. There were, however, the general principles of the science which would always have to be explained in lectures. The tradition of the Manchester school had been to keep before the student the practical application of the science, and in this connexion the lecturer dealt with the interesting subject of surface anatomy. Finally, Professor Elliot Smith mentioned the reforms which had been adopted on the continent in the teaching of this subject. The point of view of the reformers was that anatomy should be based on embryology. Anatomists must demand as their field the whole of anatomy, not mere gross human anatomy, but also fine microscopic anatomy which had been taken over by the physiologists. He thought that the physiologists would gain considerable advantage from their own point of view if they gave up histology entirely to the anatomists. Reference was made to the intimate relations between art and anatomy.

Life in Motion.

The lecture delivered by Professor W. Stirling, introductory to the course of lectures on Physiology, was entitled "Life in Motion." By means of the cinematograph the lecturer showed how cinematography could be used in schools, colleges, and universities to visualise many phenomena which the student may not have an opportunity for seeing for himself. To illustrate the application of the cinematograph to biological problems the lecturer showed a number of films on such subjects as imitations of amœboid movement, the rhythmical beating of a globule of mercury, contrasting this with the beating of the excised heart of a rabbit perfused with Locke's fluid, and the arrest of the beat by chloroform, its subsequent recovery, and finally the effects of perfusion of adrenalin on the same heart. The movements of a starfish righting itself, the movements of the tube feet of a sea urchin were also shown; but perhaps the film that most interested the audience was one showing the successive divisions of the eggs of a sea-urchin—the segmentation of the ovum—up to the formation of the pluteus stage. The audience could follow the division of the ovum first into two, then four, eight, 16, until the two layers of the embryo were formed. Many other films were shown, including one made by Dr. Comandon on the protrusion of pollen tubes from the pollen of a lily.

Oct. 10th.

LEEDS.

(FROM OUR OWN CORRESPONDENT.)

Opening of the Medical Session.

THE custom, which in the main is an excellent one, of securing the services of some distinguished member of the medical profession to deliver the address on the occasion of the beginning of a new session at the medical schools of the country, was departed from at the University of Leeds this year, and the authorities of the School of Medicine were fortunate in getting Mr. Mark Sykes to undertake the duty. Mr. Sykes, who is one of the Members of Parliament for Hull and a member of a well-known Yorkshire family, has been a great traveller, and was able to speak from his own experience of the habits and of the medical and surgical methods of the nomadic Kurds and Arabs. He gave many interesting illustrations of the singular combination of apparently deep

[1] Reports of the Society for the Study of Disease in Children, vol. viii., 1908, pp. 74 et seq.

[2] Wien, 1903, vide pp. 74 et seq.

[3] Vide Etiologie et Prophylaxie des Maladies Transmissibles par la Peau et les Muqueuses Externes, Traité d'Hygiène, fasciculus xvii., p. 618, 1911.

[4] Influence Comparée des Générateurs dans l'Hérédo-syphilis (Annales de Dermatologie et de Syphilis, tome ii., No. 2, 1911, p. 73).

scientific insight and rank superstition which prevails among these people, and it was interesting and instructive to hear from the lips of an observant layman opinions formed from such premises as to the development of the science and art of medicine. On the influence of the imagination in the processes which lead to the recovery of the patient Mr. Sykes was distinctly amusing; perhaps it may be said that anyone might succeed in being so with such a topic, but Mr. Sykes was also instructive. He correctly grasped the legitimate position of the use of the imagination in therapeutics, and stated it in such a way that probably there are few members of the medical profession who would not be in agreement with his views, or, indeed, who have not acted in harmony with them.

Leeds and West Riding Medico-Chirurgical Society.

The opening meeting of this, the fortieth, session of the Leeds and West Riding Medico-Chirurgical Society takes place on Friday, Oct. 20th, when the chair will be taken by Mr. H. Littlewood, the president for the ensuing year. This society, founded on the old Leeds Medical Club, a small body consisting mostly of the members of the honorary staff of the infirmary, and meeting in succession at one another's houses, has had a flourishing existence and an increasing membership since it assumed its present form. The number of members now amounts to 395. Last session the average attendance at the meetings was 87·7, a number which is creditable when it is considered that a large number of the members are resident in remote parts of the West Riding. During the session 1910–11 the society held 11 meetings eight ordinary, one pathological, and two clinical. One of the meetings was devoted to a discussion on the diagnosis and treatment of tuberculosis. Most of the meetings are held in the General Infirmary, but, as a rule, the pathological meetings are arranged for at the Medical School.

Appointment of a Third Assistant Physician at the Infirmary.

Some time ago, as was mentioned in this column, a decision was come to to appoint a third assistant physician to the infirmary. It was arranged that his duties should be different in details from those of the other two members of the medical assistant staff, and that the recent rule adopted by the infirmary to the effect that members of the staff should not hold any other honorary appointment involving the charge of beds should not apply to the holder of the new appointment. The object of this special exemption was to permit of there being definitely included as part of his duties the charge of a certain number of beds at the hospital for tuberculosis. Dr. G. W. Watson, who has for some time held the position of assistant physician to the tuberculosis association, has been appointed to this position.

Oct. 10th.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

Opening of the Winter Session of the Medical Faculty of the University of Liverpool.

THE opening address was delivered on Oct. 3rd at the University by Sir Charles Ball, in the presence of a large and distinguished gathering. In the evening Sir Charles Ball was the principal guest at the annual dinner of the medical faculty, which was held at the University Club, under the chairmanship of Mr. Frank T. Paul, consulting surgeon to the Liverpool Royal Infirmary. There was a large muster of professors and lecturers, besides many local medical practitioners.

Gift to St. Paul's Eye Hospital by Grateful Chinamen.

An interesting ceremony was witnessed at the Town-hall last week, when the Lord Mayor received from a deputation of Chinamen a handsome gramophone with records for presentation to St. Paul's Eye Hospital, to be used by the staff of that institution for the entertainment of the inmates. The attendance at the function included representatives of the Chinese community in Liverpool and of the hospital committee and staff. The happy thought suggested itself to the Chinese community by the kindness shown at the hospital to two Chinamen who had been patients there. They were so impressed by the attention shown to them by members of the staff and the nurses that they conceived the idea of brightening the lives of the inmates by some form of entertainment for the benefit of those temporarily deprived of their sight. The project was warmly taken up by the Chinamen of the city, and within three weeks the funds necessary for the purchase of a gramophone and two dozen records were secured. Mr. G. A. Kirkham expressed the hope that that day's ceremony would strengthen the ties of friendship existing between this country and China, and would help them all to realise that there was only one brotherhood, formed of men of every colour and clime.

Port Sanitary Dispute.

The special committee appointed last year to inquire into the administration of the hospital at New Ferry belonging to the Liverpool port sanitary authority, presented its report to Birkenhead town council on Oct. 4th. The hospital is maintained for the treatment of seaborne cases of cholera, plague, and yellow fever entering the Mersey from foreign ports, and is the joint property of Liverpool, Birkenhead, Bootle, Wallasey, Lower Bebington, and Bromborough. The Liverpool corporation, as having the largest share in the partnership, was given the entire management of the hospital on behalf of the other authorities, who are annually apportioned a share of the cost of management and of the maintenance of the patients. It was said that Liverpool was using the hospital for its own city cases and that patients suffering from small-pox and other infectious diseases belonging to the city were conveyed there by the Wallasey luggage-boats. It was also alleged that the ambulance while on the boat was frequently brought in touch with other vehicles carrying foodstuffs and general merchandise. The port sanitary officials, among whom were the town clerk and medical officer of health, repudiated these allegations. The former wrote explicitly stating that the port sanitary hospital is used only for the accommodation and treatment of *bonâ-fide* seaborne cases, while Dr. E. W. Hope was equally emphatic on the point.

Annual Dinner of North of England Graduates of the University of Dublin.

The annual dinner of the graduates of the University of Dublin resident in the North of England will be held this year in Liverpool. The dinner will take place on Saturday, Oct. 21st, at 7.30 P.M., at the Adelphi Hotel. The Right Hon. Sir Edward Carson, K.C., will preside. The local committee of management expects a large gathering at this popular function.

Retirement of Mr. Arthur Price, M.R.C.S. Eng., H.M. Prison, Walton.

By the retirement of Mr. Arthur Price from the medical officership of H.M. Prison, Walton, the official circles of Liverpool have been deprived of a notable figure. During his lengthy career in the public service he has identified himself with many movements and institutions of a patriotic and civic nature, winning the high regard of all who have at heart the cause of citizenship. Joining the service in 1882 as assistant surgeon to H.M. Convict Prison, Parkhurst, Mr. Price was promoted five years later to the post of medical officer to H.M. Prison at Birmingham, and in 1897 was further promoted to the more important post of medical officer to H.M. prison, Walton, near Liverpool. For a number of years Mr. Price was connected with the Royal Naval Reserve (Volunteers), and was one of the pioneers for the reconstruction of the disbanded Royal Naval Artillery Volunteers, now known as the Royal Naval Volunteer Reserve. He also holds the rank of captain in the R.A.M.C. (T.). Only quite recently he successfully performed a difficult operation on a dog—a feat which was a tribute alike to his skill and to his courage, in connexion with which he was presented with the medal of the Society for the Prevention of Cruelty to Animals. The dog, in trying to scale some railings, had become impaled on one of the spikes. In its agony it bit Mr. Price, who, however, pluckily stuck to the work of rescue, and ultimately succeeded in releasing the poor animal, which he afterwards surgically treated and restored to health. Mr. Price has also been decorated with the Order of St. John of Jerusalem, a distinction conferred upon him on account of his services, extending over 32 years, as a lecturer on ambulance work in various parts of the country. In the many calls that have been made upon him to deal with and report upon dangerous criminals and lunatics he

has displayed a tact and fearlessness which have won for him the admiration both of the bench and the prison officials.

Oct. 10th.

BRISTOL AND THE WESTERN COUNTIES.

(FROM OUR OWN CORRESPONDENTS.)

The University of Bristol.

ANOTHER session has begun amid change and a certain degree of confusion consequent thereupon, especially in the Faculty of Medicine. Briefly, what has happened is this. The increase of clerical and administrative work entailed by the conversion of University College into the University has necessitated an increase in the staff. Further, the Vice-Chancellor's office had to be found in a building in which it was not originally provided for. Adequate accommodation for the various offices has been secured by converting the wing used till now for the medical school into an administrative block, a step facilitated by the fact that the department of physiology had already been moved thence into the new wing opened in 1909. The only part of the wing, which hitherto has housed the medical school, that remains unaltered is the department of anatomy; the provision of a new dissecting room in any other part of the buildings was so difficult a matter that it was left alone. The principal changes which have been effected are, therefore, the conversion of the medical library into the council chamber, and the alteration of the museum, faculty room, students' room, and the pathology, medicine, and other lecture-rooms into offices. The removal of the library has been managed with considerable dispatch, and the books and periodicals are now housed comfortably in the buildings which formerly belonged to the Blind Asylum, by acquisition of which the University gains a frontage in Queen's-road. This is a main thoroughfare, and in course of time the existing Blind Asylum buildings will be replaced by a newer block more adapted to university requirements. For the present, however, the old asylum premises give convenient accommodation to the Arts and Science Library, and to that of Medicine—in the case of the latter the books find so much more room that it has been possible to set aside separate magazine and reading rooms, as well as a private reading and writing room, for members of the University staff and of the Medico-Chirurgical Society (who are part owners of the library). This removal of the library makes a difference to the meetings of the medical societies, which have hitherto been held in the old library. Last week the local division of the British Medical Association met at the Y.M.C.A. rooms, which are conveniently central, and the opening meeting of the Medico-Chirurgical Society will take place in the physiological lecture theatre of the University. The other great migration is that of the department of pathology to the top floor of the 1909 wing, directly above the department of physiology. The new pathological department will contain the public health laboratory, which until now has occupied an annexe of the old medical school wing, and also the museum, which is to be increased by contributions from the collections at the Royal Infirmary and General Hospital. Here, as in the case of the library, the extent of the accommodation is increased, but at the expense of concentration. Formerly the medical student found the departments of anatomy, physiology, and pathology, the library, and his various lecture-rooms in one compact block; now they are scattered over three blocks at some distance from each other. It remains to be seen what will be the effect of this on the medical school; the entry for this year is a comparatively good one. The annual granting of degrees will take place on Oct. 20th.

Death of Alderman C. B. Hare.

On Oct. 7th Alderman C. B. Hare was walking quietly through the Bristol Industrial Exhibition, which is being held at the Coliseum, when he fell suddenly and died in a few minutes. He was 70 years of age, and had for 40 years been a member of the city council, of which he had for some time been the "father." He served the city faithfully and unostentatiously in many ways, but in none more faithfully than as a vice-president and active member of committee of the General Hospital. Since he joined the committee, 28 years ago, he devoted the greatest energy to the service of the institution. He was particularly valuable as a financial administrator, and as such did a great deal to set the hospital in the enviable position of comparative financial stability which it now enjoys.

Notification of Cerebro-spinal Fever and Poliomyelitis.

Having obtained the consent of the Local Government Board the Bristol city council has issued a notice declaring acute anterior poliomyelitis and cerebro-spinal meningitis to be included within the provisions of the Infectious Disease (Notification) Act, 1889, for six months from Oct. 9th. This step is amply justified, for in the autumn of 1909 the number of cases of the former disease occurring in Bristol was so great as to warrant its description as an epidemic. There seems reason to believe that the total number of cases this autumn will be noteworthy.

The Salaries of Workhouse Medical Officers.

The Bristol board of guardians recently advertised for a medical officer to one of their workhouses at a salary of £100 per annum, with board and rations. No applications were received for the post, and they are now advertising the appointment with an additional £25 salary.

The South-Western Poor-law Conference.

The annual Poor-law Conference of the South-Western District was held at Weymouth on Oct. 5th and 6th, under the presidency of Sir Thomas Dyke Acland, and was largely attended by delegates from all the unions in Cornwall, Dorset, Devon, Somerset, and Wilts. Sir Thomas Dyke Acland, in his presidential address, alluded to the present wretched condition of filthiness and misery to be found among the poor living in the country, and dwelt on the importance of rural housing. A resolution was passed stating that the proposals of the County Councils Association were impracticable, and would not result in any corresponding improvement in administration, and resolutions were also passed in favour of immediate legislation in regard to the treatment of feeble-minded persons, and approving of the principle of combinations in unions for the joint treatment of imbeciles, &c.

Sanitary Inspectors' Association.

The annual meeting of the South-Western Centre (comprising six counties) of the Sanitary Inspectors' Association was held at Weston-super-Mare on Sept. 30th. There was a good attendance. Mr. J. A. Robinson, chief meat and food inspector for the Port of Bristol, gave an interesting address on the Need of a More Comprehensive Inspection of Food. He urged the importance of more uniformity in the inspection of tuberculous meat. He said that the Dairies, Cowsheds, and Milkshops Order had done much to assist in giving a pure and clean milk-supply, and he thought the promised Milk and Dairies Bill would materially strengthen the local authorities in their control over the milk-supply. In mentioning the inspection of "canned foods," he said it would be a great advantage if it were made compulsory to state on the cans the date of manufacture.

Oct. 10th.

WALES.

(FROM OUR OWN CORRESPONDENT.)

Tuberculosis in Cardiff.

THERE has been a steady fall in the death-rate from phthisis in Cardiff during the past 30 years. In 1881 the rate was 3·0 per 1000, and in 1910 it was 1·0 per 1000 of the population. There are, however, certain parts of the borough where the disease appears to be unduly prevalent. In the south ward, for example, where there is a population of about 10,000 persons, the death-rate in 1910 was 2·5 per 1000, and in previous years the rate in this ward has been above that recorded for the whole borough. At the end of 1910 a dispensary for tuberculous patients was opened in Cardiff, two rooms being set aside for that purpose in the basement of the city hall. The assistant medical officer of health, Dr. E. Fairfield Thomas, attended from 6 to 8 o'clock on three evenings in each week and had the assistance of the lady health visitor. During the 11 months ending August last there have attended the dispensary 787 patients. Of this number 20 have died, 11 are reported to be much worse, 32 are said to be stationary, 291 are improved, and 44 are much improved. Tuberculin treatment was carried out only at the end of the

period named. In a report on the whole question, recently issued by the medical officer of health, Dr. E. Walford, it is pointed out that the accommodation available for the dispensary has become entirely inadequate, more especially as the rooms are also used for the examination of school children and for infant consultations. In Dr. Walford's annual report for 1910 on the health of Cardiff, Dr. Thomas expressed the opinion that even by the end of that year the work had become so exacting as to require the whole-time services of a medical officer, for in order to obtain the best results he should visit the homes of the patients who attended at the dispensary.

A Municipal Lodging-house for Women in Cardiff.

The question of providing a municipal lodging-house for women in Cardiff has been actively engaging the attention during many months past of a committee of ladies, with whom Dr. Erie Evans has been prominently associated. The need for such an institution has been demonstrated by the fact that there is in the borough only one registered lodging-house for women, and that contains accommodation for 49. The Salvation Army provides accommodation for 50 more, and in unregistered houses about 100 can be received. As a result of representations which were made by this committee the health committee of the corporation held an inquiry for the purpose of ascertaining whether there was any necessity for such a lodging house, and subsequently recommended that the principle of a municipal lodging house "for women only" should be adopted. After various buildings had been inspected by the medical officer of health and the city surveyor it was decided to rent two centrally situated houses formerly in the occupation of the Salvation Army. Accommodation is proposed for 20 beds. The charge per night is to be 5*d.*, and it is estimated that the undertaking will be a charge upon the rates.

Housing Conditions in Gelligaer.

At a recent meeting of the district council very disquieting statements were made with respect to the overcrowding and insanitary state of a large number of houses in the Gelligaer urban district, which adjoins Merthyr Tydfil, and where there was a population at the last Census of 35,000 persons, an increase of over 18,000 since 1901. In one locality there was stated to be an average of eight persons to a house. At a subsequent meeting of the housing committee of the council the medical officer of health, Dr. W. W. Jones, reported the result of his examination of 45 houses in the district of Pontlottyn. Of these he considered that at least 14 were uninhabitable and only three were in a reasonably good sanitary condition, the remainder being capable of repair. Some of the dwellings were nearly 100 years old, and as the leases would soon fall in it was unlikely that the present owners would spend much on their repair. Dr. Jones advised the council to take immediate steps to erect 50 houses, and expressed the opinion that later another 50 would be necessary. The council decided to seek for suitable sites with a view of carrying out the recommendation of the medical officer of health.

Oct. 10th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Veterinary Degrees in the University of Edinburgh.

A SCHEME of coördination has been arranged between the University of Edinburgh and the Royal (Dick) Veterinary College, whereby the degrees of B.Sc. and D.Sc. in veterinary medicine will be awarded. The scheme, which awaits the approval of the Privy Council, provides for one year of study to be spent at the University and four academic years at the Veterinary College.

The Dr. Jessie Macgregor Lecture.

In accordance with the conditions laid down by the trustees of the Dr. Jessie Macgregor Fund, Dr. Agnes Ellen Porter, to whom the prize was awarded this year, delivered a lecture, entitled "A Short Survey of Immunity in Tuberculosis," in the Anatomical Department of the University of Edinburgh on Sept. 29th. The treasurer of the Royal College of Physicians of Edinburgh, Dr. Norman Walker, who introduced Miss Porter, referred to the high standard of the work submitted by the candidates for the prize. The next award will be made in 1914.

Opening of the New Pathological Institute at Glasgow Royal Infirmary.

An important addition to the equipment of the Royal Infirmary, Glasgow, has just been completed, and was formally inaugurated last week by Sir William Osler. This is the new Pathological Institute, which is handsomely housed in a new building and is part of the great reconstruction scheme of the Royal Infirmary itself. Sir William Osler said he wondered if they appreciated in Glasgow the delightful memories that crowded the mind of a man familiar with the story of medicine in Great Britain when the name of their Royal Infirmary was mentioned—memories of men who by their life and doctrine had set forth not alone the very best the profession had had to offer, but the very best that man had ever offered to his fellow men. He commended them for adopting the name "institute." He was sure that the name indicated that they felt the infirmary would bear its share with the University in advancing scientific medicine. For an institute was something more than a deadhouse, and very much more than an ordinary pathological laboratory; it was the cerebrum of the infirmary, the place where the thinking was done, where ideas were nurtured, where men dreamed dreams, and thoughts were materialised into researches upon the one great central problem that confronted the profession in each generation—the nature of disease. Observation, plus thinking, had given them the vast stores of knowledge they now possessed of the structure of the bodies of living creatures in health and disease. There had been two inherent difficulties—to get men to see straight and to get men to think clearly; but in spite of the frailty of the instrument the method had been one of the most powerful ever placed in the hands of man. The institute which they opened that day was a manifestation of the new spirit. In this great field of experimentation and research he cited names of interest in Glasgow, such as Professor Andrew Buchanan and Lord Lister. He then went on to refer to the relations of the infirmary with the University. With two modern hospitals the problem of the relation of their pathological departments to the pathological department of the University had been settled in the only way. In the interest of both institutions the union had been made organic, and the professors of the subject in the University had the same relation to the pathological laboratories of the hospitals as the professors of surgery had to their wards in the infirmaries. In addition he said the institute existed for the benefit of the public. There was not a patient in the wards who would not be helped by the work done in it. From laboratories had come not alone the war-cries of modern medicine, but the chief weapons against the acute infections. In connexion with the realisation of the preventability of infectious diseases, he stated that the sanitary story of the city of Glasgow in the last half century was one of which they might be justly proud. To wipe out typhus, to have made typhoid a last-ditcher, to have cut in half the mortality from tuberculosis, were among the peace victories in which the citizens of Glasgow had shared. In conclusion, Sir William Osler stated that in the field of medicine four great problems awaited solution. In the first place, literally thousands of workers were struggling to unravel the mystery of cancer. Secondly, the exanthems were still with them, still killing thousands, and the world awaited the researches which would reveal the cause of measles, of scarlet fever, and of small-pox. Thirdly, though perversions of metabolism were every day yielding up their fascinating secrets, the sure and certain studies that alone could give control of such common diseases as diabetes, gout, and arthritis were lacking. Fourthly, they were entering a new chapter in the researches upon the internal secretions and the functions of these mysterious glands, so insignificant anatomically, but so potent in their influence upon growth and nutrition. In addition, he said, there were scores of minor problems to be solved by this generation, and there was much knowledge to be sifted before it could be used to the best advantage. Considering the enormous quantity of sap they had collected, they might feel disappointed at the comparatively small bulk of sugar left after complete boiling; but sweeter or better sugar had never been tasted than that of their making, and among all samples in the market no brand ranked higher than that from the old Glasgow Royal

infirmary. It was for them in the new infirmary, and in that splendid institute, to see that the quality was maintained.

Scottish Universities and the Inclusive Fee.

A meeting of the University Court of St. Andrews was held on Sept. 30th. It was then reported that the resolution of the last meeting of the court, adopting the recommendations of a conference of the four Scottish universities with reference to the proposed institution of inclusive fees in the faculties of arts and science, had been intimated to the Lords Commissioners of H.M. Treasury and to the other Scottish universities, with an announcement that the University of St. Andrews was prepared, if the other Scottish universities were also willing, to introduce inclusive fees in the session 1911–12. The University Courts of Glasgow and Edinburgh had not yet discussed the proposals of the conference, but the University Court of Aberdeen had stated that they were prepared to introduce the inclusive fees in 1912–13. A letter was read from the Lords Commissioners of H.M. Treasury, in which it was stated that it was not to be assumed that the additional grants to the universities would be continued next year unless the arrangement as regarded the inclusive fees was extended before the beginning of the academic year 1912–13 to all the faculties except that of divinity; and in any case the question of increasing the grants to the full sum contemplated by the Treasury could not be considered until the inclusive fees had been instituted in the faculties of law, medicine, and applied science. The University Court agreed to invite the other Scottish universities to appoint representatives, and reappointed Principal Sir James Donaldson, Principal Mackay, and Professor Burnet to represent the University of St. Andrews.

Medical Inspection of Schools in Kincardineshire.

In the second report to the secondary education committee of Kincardineshire submitted by Dr. R. King, the assistant school medical officer for the county, it is stated that the number of children examined during the year was 4412, of whom 2780 were found defective. Many of these defects are not of a serious nature, and Dr. King says that there seems to be no valid reason why the great majority of the defective should not get rid of their defects and take their place among other children. The statement shows that the most common defects are: enlarged glands, 668 boys, 621 girls, total 1289; decayed teeth under 6 years, 425 boys, 401 girls, total, 826; nits in hair, 175 boys, 536 girls, total 711; enlarged tonsils, adenoids, 272 boys, 277 girls, total 549; defective vision, 168 boys, 267 girls, total 435; external eye diseases, 112 boys, 152 girls, total 264. 78 per cent. of the children had suffered from measles, 70 per cent. from whooping-cough, 6 per cent. from scarlet fever, 2 per cent. from diphtheria, 36 per cent. from mumps, and 22 per cent. from chicken-pox. From the statistics it appears that rural and urban schools have about the same percentage of defective children, and that in nearly every case the number of defective girls is larger than that of defective boys. This is largely due to the greater number of girls with nits in their hair and the greater number with defective vision. Kincardineshire at almost every age exceeds the standard for the whole of Britain as to height and weight, but at the age of 14 the averages for height and weight of both boys and girls are below the standard. At ages 12, 13, and 14 the girls are superior to the boys in both height and weight, the boys appearing to stand still, while the girls advance rapidly. At a later age the boys seem to shoot ahead while the girls remain stationary, thus attaining the relative standards maintained throughout life.

Oct. 10th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Poor-law Medical Officers and the Insurance Bill.

AT a meeting of delegates of dispensary medical officers, held in the Royal College of Surgeons in Ireland, Dublin, on Oct. 4th, the following resolutions were passed:—

1. That we, the delegates assembled here to-day, view with alarm the amendment of the Insurance Bill suggested by the Select Committee of the Irish Party, proposing to delete the medical benefits, while retaining the sickness benefits, thus throwing over on us an enormous amount of extra work, without any corresponding remuneration, and that a deputation of dispensary medical officers be elected to wait on the Irish Parliamentary Party and Mr. Lloyd George.
2. In the event of medical benefits being denied to Ireland under the Insurance Bill, we hereby recommend our *confrères* in the dispensary service to refuse to carry out the work imposed on us, unless we are properly compensated for our extra work.
3. That the medical benefits of the Insurance Bill, as applied to Ireland, be not deleted.
4. That the deputation appointed to-day confer with the dispensary medical officers appointed by the Conjoint Committee of the British Medical and Irish Medical Associations, with a view to a settled policy, before waiting on the Irish party and Mr. Lloyd George.

Public Health of Dublin.

The corporation of Dublin has accepted the report of the public health committee recommending the appointment of an assistant medical officer of health. Up to the present the medical officer of health, who is not himself a whole-time officer, has not had any qualified assistant in his department. The corporation has also directed its paving committee to "ascertain whether more sanitary methods of removing the street dust could be adopted, either by sprinkling with tar or otherwise, so as to prevent citizens who keep their windows open at night from being poisoned with the dust." Steps are being taken also to obtain control of the various lanes and alleys in the city, which are not in the charge of the corporation. There are at present 894 such lanes, with a total mileage of some 38 miles.

Retirement of the Registrar of the Royal College of Surgeons.

Old students of the Royal College of Surgeons in Ireland will learn with regret that Mr. G. F. Blake, the registrar of the College, has found it necessary after a long period of service to resign his office. At a meeting of the Council held on Oct. 5th, in a resolution accepting his resignation with great reluctance and regret, the President, Vice-President, and Council state that "during the long period of 31 years that Mr. Blake discharged the onerous duties of registrar to the College, his devotion to its interests, his courteous deportment to all with whom he had relations, and the admirable manner and efficiency in which he carried out the important work connected with his office were beyond all praise. The President, Vice-President, and Council feel that by the resignation of Mr. Blake the College has lost the services of a most efficient officer, and a kind friend, whom it will be difficult adequately to replace. They hope that in the many years which they trust are before him he will enjoy his well-deserved rest from duty. He may at the same time be assured that his valuable services to the College will long be remembered and appreciated."

Emigration from Ireland.

According to the Registrar-General's return, during the month of September 3443 emigrants left Ireland, a decrease of 1087 compared with the corresponding month of last year. The total for the first nine months of this year is 25,782, compared with 27,539 for the first nine months of 1910. Of the 3443 emigrants in September, 442 were from Leinster, 917 from Munster, 1406 from Ulster, and 678 from Connaught. The destination of 2747 was the United States, 441 Canada, 12 South Africa, 65 Australia, 19 New Zealand, 130 England and Wales, and 29 Scotland. Out of 2578 steerage passengers to the United States 761 had their passages paid for in America.

Royal College of Physicians of Ireland.

The following were admitted Licentiates and Members of the College on Oct. 6th:—Charles Preston Ball, M.D., William Porter MacArthur, M.D., Lieutenant, R.A.M.C., and Robert James Rowlette, M.D.

The "Handy Woman" Again.

The North of Ireland papers of Oct. 5th contain the account of an inquest held by the coroner of South Armagh in reference to the deplorable death during her confinement of a farmer's wife at Dromilly, near Balleek. It would appear that a fortnight before the event occurred the husband arranged with a fully trained and certificated midwife who lives at Mountnorris to attend his wife; but on Sept. 31st, when his wife became unwell, he, at her request, went for a neighbour and not for the midwife. On the next morning (Oct. 1st) the child was born at 6.30, and about 8 o'clock the woman who acted as "handy woman" went home. At half-past nine, three hours after the birth of the child, the mother died, and Dr. G. M. Irvine deposed that the cause was post-partum hæmorrhage. The jury found that death was due to post-partum hæmorrhage, the foreman adding

that the Crown, if they felt so disposed, "could pursue the matter wherever they like afterwards."

Water Scarcity.

Never in the recollection of anyone has there been such a water famine as at present exists in the North of Ireland, a place where, as a rule, there is a heavy rainfall. The question is now becoming a very grave one for Belfast, where the water is no longer turned on to the houses between 5 o'clock at night and 10 the next morning. In Londonderry there is little over a week's supply, in Belfast about three weeks', and in the former city many manufactories are closed, and the engines of the railway trains have to get their supplies in the country stations.

The Queen's University of Belfast.

The medical session opened on Oct. 10th, when the introductory address at the Royal Victoria Hospital was given by Dr. John E. MacIlwaine, who has succeeded the late Dr. W. B. McQuitty as assistant physician. During the day systematic lectures in the various classes began at Queen's College.

Oct. 10th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The Milk Question in Paris.

AMONG the many problems that Paris has faced this year the lack of milk has caused great uneasiness for many weeks. Not only has milk been increasing in price, but, like butter, the supply also has diminished. Until recently the increase in price has only been expected, but now it has become a fact. A large milk concern in Paris has announced that from Oct. 15th the price of milk will be increased a halfpenny a litre, and, further, the population will be put on a milk ration, for since the end of July the daily amount of milk brought into Paris has fallen by 200,000 litres. Owing to the absence of a large number of Parisians on vacation this deficit has hitherto been of less moment, but the situation has now become alarming. The prefect of police has taken cognisance of it, and has summoned a conference of the three principal wholesale milk dealers in Paris to inquire into the causes of the milk famine and to concert measures to deal with it. This year, because there has been scarcely any grass, cattle have had to be fed with the hay crop. Fortunately this has been abundant. Nevertheless, the cattle have had to be put on a ration, and the absence of fresh grass as well as the diminution of food has resulted in a deficiency of milk. Aphthous fever has still further increased the difficulties. It has ravaged whole herds of cattle in the department of the Nord and in Normandy and also in the departments of the Midi. Those cows that have survived no longer furnish milk. Frequently they have had to be slaughtered on the first symptoms of the disease. The wholesale milk dealers estimate that the production of milk has become lowered by one-third. On all sides they have endeavoured to find fresh sources of supply, and have scoured even the most remote provinces for the purpose. In this manner they have succeeded now in limiting the deficit to a fifth, but there will be still a great deficiency of milk in Paris during the coming winter. The prefect of police has decided that care must first be taken of the infants' needs. The restricted ration will be enforced only on those who will hardly suffer much from it. Mothers of families with children under a year old are invited to state the amount of milk needed by them and they will be first served. At the present time the milk costs, according to neighbourhood, from 3*d.* to 4*d.* per litre.

Tetanus as an Accident of Work.

The Court of Appeal of the Seine pronounced judgment on an interesting point on Oct. 4th. The question arose whether a man who died from tetanus on Dec. 10th, 1910, could be regarded as the victim of an accident of work, his widow testifying that while at work on Dec. 10th he had sustained a slight puncture of the right foot. The court decided that the proof of the coincidence of the puncture with the beginning of the usual ten days' incubation of tetanus, and in a part of the body especially predisposing to that disease, imposed a liability on the master. The latter's insurance company, therefore, has been ordered to pay to the widow a life annuity of 490 francs, and also an income of 819 francs for the deceased's minor children.

Oct. 10th.

SWITZERLAND.

(FROM OUR OWN CORRESPONDENT.)

Swiss Balneological Society.

THE twelfth annual meeting of the Swiss Balneological Society took place at Zürich on Oct. 1st and 2nd, Dr. Hans Lötscher being local president. The number of members has risen from 111 to 124. The German edition of the *Swiss Balneological Review* has been very favourably criticised; the French edition will appear shortly, and the English one in the spring of 1912. Every year balneological excursions are organised, as in Germany and France. The question was debated whether Switzerland could undertake in 1914 the International Balneological Congress, which brings together several thousands of members. It was decided that such an undertaking would be possible only with the financial support of the Swiss Societies of Hotelkeepers and of Commerce. As regards the scientific part of the proceedings, Professor Sommer of Zürich lectured on the therapeutic application of the newest rays (X rays and radium emanation). Dr. Lötscher spoke on the importance of the town of Zürich as an intermediate climatic station. He mentioned that the mortality had decreased by 3 per cent. in the last 20 years, and that the ratio of deaths from tuberculosis had declined from 22·8 to 18·7 per 10,000 inhabitants. The mortality from typhoid had decreased from 6 per 10,000 to 0·8 per 10,000 inhabitants (i.e., 15 cases a year). He referred to the excellent water-supply and various sanitary improvements. Professor Dr. Schweitzer lectured on the radio-activity of various Swiss springs, of which about 300 so far have been investigated, and of these Disentio in the Grisons was given first place. Dr. von Muralt of Davos read a paper on the Psychic and Nervous Symptoms in Tuberculous Patients. Dr. Diebold of Zürich spoke about the inhalation treatment adopted at the sulphur baths of Baden, near Zürich, and Dr. Markwalder, of Baden, read a paper on After-treatment of Stiff Joints at the Spa, Baden, the importance of which, as well as that of Schinznach, is increasing from year to year. The next annual meeting of the society will take place at Zermatt in 1912.

Treatment of Cardiac Disease.

In the *Korrespondenzblatt für Schweizer Aerzte* of Oct. 1st Professor Eichhorst of Zürich has published a concise article on the treatment of cardiac disease. In the treatment of cardiac insufficiency he considers rest and a milk diet of primary importance. Medicinally, a combination of powdered digitalis (not the infusion), 2 grains, with diuretine, 16 grains, given three times a day, stands first. Digalen, introduced into therapeutics by Professor Cloetta of Zürich, is also recommended. Powdered leaves of digitalis, 2 grains, and calomel, 1 grain, are often very efficacious. Finally, a properly titrated tincture of strophanthus or Boehringer's strophanthine must be mentioned. Massage of the œdematous lower extremities is often to be recommended, together with passive movement. Venesection on the lines adhered to by Professor von Liebermeister may give surprising results. Excitement of any kind is very detrimental, as shown by three fatal cases lately observed in Professor Eichhorst's clinique. Carefully prescribed carbonic acid baths, with or without the addition of sea-salt and Nauheim exercises, benefit certain cases when given under strict medical supervision. In cases of arterio-sclerosis with symptoms of angina pectoris, morphia or pantopon can be given with advantage from time to time. The nitrites, adrenalin, and the quite modern vasotonin must not be forgotten.

Zürich, Oct. 5th.

LONDON SCHOOL OF TROPICAL MEDICINE.—The annual dinner of the school will be held on Tuesday, Oct. 17th, at 7.15 for 7.30 P.M., at Prince's Restaurant, Piccadilly, W., under the chairmanship of Dr. M. Cameron Blair, senior sanitary officer, Northern Nigeria. Miniature decorations will be worn.

VIENNA.

(FROM OUR OWN CORRESPONDENT.)

Formation of a Technical Museum in Vienna.

SOME very influential Austrian commercial men and educationists have taken steps to bring together the existing scattered collections of objects dealing with the development of technical occupations and to make such additions as may be required for the adequate representation of modern methods and conditions. In commemoration of the sixtieth anniversary of the Emperor's accession the State and the City of Vienna have coöperated in the formation of a new museum, the foundation-stone of which was laid on June 20th, 1909, and the building, which covers an area of over 20,000 square yards and is situated opposite the Imperial Palace of Schönbrunn, is now nearing completion. The purpose of the museum is to illustrate the development of handicrafts and industries in historical succession, and in connexion with it periodical exhibitions will be held so as to constitute it a centre of public education in such matters. A considerable stock of specimens has already been acquired for the museum, and technical scientists, manufacturers, and craftsmen of all countries are invited to assist the museum in securing suitable objects for exhibition, such as tools, machines, apparatus, models, materials, descriptions of methods of working, plans, books, illustrations, manuscripts, and information of all kind pertaining to industrial technology. The exhibits will be subdivided into several sections, such as mining, practical applications of electricity, chemistry, and several others. Special medical interest attaches to the section dealing with the preparation and distribution of food and beverages, and to the section on public health, which includes the sanitation of buildings, water-supply, drainage, systems of heating and lighting, appliances and methods for first aid, Red Cross stations, hospital railway trains, hospital ships, and town planning. In the section on chemistry, the pharmaceutical department, with its illustrative specimens of old and new remedies, will no doubt be of interest to medical practitioners. Particulars can be obtained from the office of the Technical Museum, Vienna I., Ebendorferstrasse 6.

Difficulties in Connexion with the New Clinics.

The building of the proposed new clinics has been suddenly interrupted by a controversy between the State and the corporation known as the "Spitalsfond," which is responsible for the upkeep of hospitals. This incident is a good illustration of what may happen when an antiquated bureaucratic institution is called upon to undertake a great task. The Government gave at the outset 20 million kronen (£800,000) for the purpose of erecting the new General Hospital, and the Spitalsfond ought, in addition, to have provided a similar sum by selling the ground on which the old hospital stands, but it is now found that after five clinics have been erected and nearly all completed, there is no more money available for the erection of the further necessary institutes. The officials of the Spitalsfond, moreover, declare that the clinics remaining in the old General Hospital need not be moved into new buildings, but can extend themselves into the premises vacated by the five clinics, which are now located in the new hospital. The fact that these old premises are of an antiquated type incompatible with modern requirements does not count for much with the financial magnates of the Spitalsfond, who say that they have no money, and whose reply to all remonstrances is, "If the new clinics are wanted, then let him pay for them who wants them." The indignation of the public at the attitude of the officials has led to bitter words being spoken and written about the matter not only in medical circles but also by the lay press. The Government, however, did not lose patience, and after prolonged negotiations, from which the old political enmities were with difficulty excluded, an arrangement was arrived at ensuring the continuance of work on the requisite new institutes, which are to be completed within five years.

Disappearance of a Historic Building.

An interesting old building is about to be pulled down in accordance with a scheme of street widening. It formerly belonged to the medical faculty of mediæval Vienna, and in it the first regular necropsy on a human body in a German-speaking country took place. Owing to religious prejudice such a procedure was extremely rare, and medical men had no means of making themselves acquainted with the position of the viscera except by opening the bodies of domestic animals. In the year 1404, however, the Emperor Frederic II., an enlightened man, permitted the dissection of a male corpse for the benefit of the students and doctors of medicine every five years; it was at the same time ordered that this dissection should take place secretly and that a mass should be read after it was finished and before the corpse was buried. Only six necropsies took place in Vienna in the fifteenth century—namely, in the years 1404, 1418, 1444, 1452, 1455, and 1459. The first female body dissected in Vienna was that of a woman who was hanged as a witch in 1452, together with five other unhappy victims. This necropsy was conducted by "Master Jacobus, the chirurgien," a German, whilst the first complete dissection was performed by the Italian scientist, Galearo of Padua, who devoted a full week to it! It is interesting to note that when the house became the property of Roman Catholic monks a solemn "purification" of the building from the sins committed in it by the prosectors was considered an absolute necessity. The above-mentioned dates are those which have obtained historical sanction, but from the registers of the faculty in this city it would appear that some other necropsies, at least of a partial nature, must have taken place here too, for the anatomical knowledge of the Viennese prosectors could not have been obtained solely from the dissection of the lower animals.

BUDAPEST.

(FROM OUR OWN CORRESPONDENT.)

Conveyance of Infectious Diseases by Milk.

IN Nagyvárad, where two years ago a typhoid epidemic claimed about 300 lives, the sanitary board has issued small pamphlets among milk dealers, instructing them on the danger arising from contaminated milk. A great many dealers have also been fined for not returning their milk cans to the dairies clean and dry. Tuberculosis is very prevalent among the cows. The dairy inspectors have to pay special attention to this fact. To the public the following instruction has been sent. "Typhoid fever, scarlet fever, and diphtheria are sometimes conveyed by milk, especially typhoid, if the cans and bottles are washed in foul water and are not sterilised. Cities well supplied with water of good quality and having a modern sewerage system derive typhoid fever only from contaminated country milk or vegetables, or by the return of people in the autumn from less sanitary places. The bacteria in milk produce acids and toxins, which are injurious to infants and invalids. To destroy these milk is often pasteurised. This, however, is somewhat objectionable, as its destroys certain enzymes that are necessary for the digestion of the milk. It is easy enough, by diluting pasteurised cow's milk and adding milk sugar, to obtain milk identical in percentage of its principal constituents with mother's milk, but the trouble due to the indigestibility of the caseins remains; therefore, mother's milk is about the only thing for the baby."

War on Trachoma.

With the opening of the public schools the department of health renews its active struggle against trachoma. Inspectors are to visit every building as soon as possible, and the eyes of every child will be examined for traces of the disease, which is gradually beginning to give way under the continued assaults of the department. Children suffering from trachoma will be kept from school until they have undergone an operation or had appropriate treatment. The department will perform the necessary operation and administer treatment without charge. A certificate from a physician that a child has begun treatment will obtain readmission. It is believed that this inspection will show a great falling off in the number of trachoma cases. After the examination for trachoma has been completed it is proposed to test the eyes of the school children for defective vision.

UNITED STATES OF AMERICA.

(FROM OUR OWN CORRESPONDENTS.)

Danger of Water Famine Averted.

THE unprecedentedly heavy rains of the past few weeks have saved New York from what would have been a serious shortage in the water-supply. The borough of Manhattan, containing some 2,000,000 inhabitants, would have been the sole sufferer among the five boroughs, but as it is the site of all the principal hotels, theatres, public buildings, as well as of the worst slums of the city, it would have felt the want of its good water most grievously. Just before the beginning of the heavy rainfall the health authorities had begun an attempt to purify the water remaining in the reservoirs by the use of chloride of lime; 700 cases of typhoid fever occurring in ten weeks had awakened them to the gravity of the situation. It was found that part of the supply was coming from a small stream that received the dejecta of a village in which there were several cases of typhoid fever. All danger is now passed, and New York has resumed its usual extravagant use of water.

A New Inebriety Hospital.

The commission appointed by Mayor Gaynor to consider means for dealing with habitual inebriety met on Sept 12th at the City Hall and decided first to select a suitable site for the contemplated hospital for inebriates, which must be found not more than 35 miles from the city. Legislation will be urged to permit the incarceration of chronic drunkards without the permission of their relatives or their own consent.

Plans Further to Reduce Infant Mortality.

The committee for the reduction of infant mortality, of the New York Milk Committee, expresses itself as satisfied with the results obtained by the allied agencies this summer. It will now turn its attention to the prevention of infant deaths due to congenital troubles, which cause about 17 per cent. of all infant deaths. The committee is giving attention to 1000 expectant mothers to enable them if possible to bring into the world children strong enough to meet the stress of life. An arrangement will be made with the Russell Sage Foundation by which a special nurse will be detailed for this work. In addition to medical care and hygienic precautions, help will be provided if the mother is overworked. No midwives will be permitted to handle any of these cases. After confinement rest will be provided for the mothers, and the children will be referred to the milk stations.

Death of a Medical Journalist.

Dr. De Santos Saxe, a young urologist and gynæcologist, died in his thirty-fifth year on Sept. 10th. He was one of the assistant editors of the *New York Medical Journal*, and his death makes a second gap in the *personnel* of that publication. Dr. Saxe had command of five languages, and was a promising writer in addition to his professional attainments.

Wholesale Destruction of Stray Animals.

The New York Society for the Prevention of Cruelty to Animals has been collecting stray dogs and cats since June 1st last. During that time 113,186 animals have been painlessly put to death, the record for a single night being 886 cats. Stray animals are now believed to be carriers of infection and the society's crusade thus serves a double purpose.

Compulsory Antityphoid Vaccination in the Army.

Major-General Leonard Wood, who, it may be remembered, was originally an army surgeon, issued an order on August 28th making it compulsory for every officer and enlisted man in the United States Army under 45 years of age to subject himself to vaccination against typhoid fever. Heretofore, it has been voluntary on the part of either officer or private to subject himself to what was considered an experiment. The War Department is now thoroughly convinced of the efficacy of antityphoid vaccine.

Vacancies in the Philippines.

The United States Civil Service Commission announces an examination to secure eligible medical men for vacancies in the positions of bacteriologist and pathologist in the Bureau of Science at Manila. The salary is £400 per annum, with opportunities for promotion. It has recently been difficult to secure men to fill these positions, just as it is hard to persuade young practitioners to present themselves for examination for positions in the army, and especially in the navy. The pay of surgeons in the army and navy is about the same as in Great Britain, although no American surgeon reaches the emoluments of the English surgeon-general.

A Scandal about "Fee Splitting."

Certain members of the Erie County Medical Society are accused of fee splitting, or dichotomy. This practice consists of division of the fee for a surgical operation between the surgeon who performs the operation and the medical attendant who sends the patient to that particular surgeon. It is customary for the medical attendant to accompany his patient to the surgeon, and patients are prone to consider such a trip as a friendly duty on the part of their adviser, and seldom offer to defray even his travelling expenses. In its least objectionable form the fee splitting has been restricted to the surgeon's including the advising practitioner's expenses in his bill; but the practice has quickly outgrown this simple form, and certain medical men, it is alleged, have made a custom of sending their patients to the surgeon who was willing to pay the largest commissions. Reprehensible as this custom is, it is an inevitable outcome of the crowding of the profession by the small, proprietary medical schools, chartered, generally with great pride, by communities that have been newly furnished by the Federal Government with a State constitution. The various States are only now waking up to the evils which they, unthinkingly and with mistaken liberality, fostered years ago.

Hygienic Precautions in Secret Societies.

A Chicago alderman has come to the conclusion that danger of infection lurks in the "hoodwink," or blindfolding bandage, used on candidates for admission to various secret societies, and that serious eye diseases might be communicated by its use. The alderman, who is a medical man, proposes to introduce a city ordinance to compel the use of a new bandage for each candidate, or the interposition of a piece of fresh sterile gauze between it and the eyes.

The Mortality from Patriotic Crackers.

Owing to regulations passed in various cities and States forbidding the use of giant crackers on July 4th, the number of deaths from their use has fallen from 466 in 1903 to 57 in 1911, and of the non-fatal injuries from 3983 to 1546.

Oct. 2nd.

AUSTRALIA.

(FROM OUR OWN CORRESPONDENT.)

A Curious Fatality.

A VERY curious occurrence involving the death of a young medical man took place at St. Kilda recently. Three young men who had been playing tennis together entered a small bathroom for the purpose of having a hot shower bath. The bathroom was a very small apartment, almost without ventilation and containing a gas heater. They locked the door on entering. About half an hour later a message was taken up to one of them, but no response could be elicited from within the bathroom, although the bath tap could be heard running. The door was forced and the three occupants of the room were seen lying apparently unconscious on the floor. On dragging them out two were found to be still breathing, but the third was dead. The young man who thus lost his life was Dr. T. L. Gill, a recent graduate of the Melbourne University, who after a brilliant student career had held resident appointments at the Melbourne and Children's Hospitals, and had acted as demonstrator of pathology in the University. He was about to be married and to begin private practice. The survivors can give no clear account of what happened. All that is remembered by one of them is that he heard Dr. Gill, who was in the bath, complain of sudden dizziness, and then everything became blank. The other recollects nothing. A necropsy showed death to be due to suffocation, and the inquiry was adjourned. It is supposed that death was due to carbon-monoxide poisoning.

State Sanatoriums.

In Victoria the Government has now established three

sanatoriums for consumptives. At Greenvale there are 67 patients, and the highest number has been 82. This is stated to be chiefly an educational institution and patients are retained there only three months. At Amherst there is accommodation for 65, with a present total of 19. At Daylesford four patients are in residence. Before the end of the present year a home for advanced and hopeless cases will be opened at Cheltenham and will accommodate 100 patients. The total number of probable cases in Victoria has been estimated at about 5000.

Health of South Australia.

The Registrar-General for South Australia reports a total population of 430,000 in an area of 380,000 square miles. The infant mortality figure is the lowest in the world. The death-rate from phthisis is below that of Victoria, but higher than that of any other State except Tasmania. A very disquieting feature of the report relates to vaccination. During 1910 the births numbered 10,540, while only 1800 successful vaccinations were recorded. The total amount paid by Government to 191 public vaccinators was £293. The marriage rate for 1910 is the highest yet recorded.

Prevalence of Syphilis.

At the last Australasian Congress there was marked difference of opinion as to the prevalence of syphilis in Australia. During 1910, as I explained in my last letter, Dr. Burnett Ham of Victoria obtained a Government grant to have a free test by Wassermann's method of any specimen forwarded from the metropolitan area. Syphilis was gazetted notifiable under impersonal conditions and an account of each specimen was sent as regards sex, age, and disease. The report of the advisory committee, signed by Professor H. B. Allen, from which I was able to quote, stated that 5000 distinct cases were registered and examined. Of these 1900 gave a positive reaction and over 400 a partial reaction. The report said: "Experience has shown that out of 100 cases of syphilis only about 60 will give a positive reaction, so that 60 positives represent 100 cases of syphilis. Therefore 1900 positives represent 3167 cases of syphilis, or 63·3 per cent. out of the 5000 reported. On the metropolitan population of 600,000 this means that more than 0·5 per cent. were found to be syphilitic." The *Australasian Medical Journal* objects that these figures cannot be taken as statistically accurate, but withholds definite criticism until a fuller analysis is made, which is being done for the Sydney Congress in September. The whole of the 5000 tests were performed by Dr. Konrad Hiller. In conjunction with the supposed result of the report a "campaign" has been inaugurated to endeavour to lessen the incidence of syphilis. The daily press has viewed the matter sympathetically, and the Government promises to act on any practicable suggestions laid before it. The feeling against Contagious Disease Acts and lock hospitals is even stronger here than in England, so that it is difficult to see what legislative measures would be considered.

Ninth Australasian Medical Congress.

The arrangements for the Ninth Australasian Medical Congress are now well forward, and an interesting gathering is assured. In Medicine attention will be directed to arteriosclerosis. In Surgery the chief topics will be the Surgery of the Large Intestine, the Treatment of Fractures, and Surgical Shock. In Obstetrics the Hæmorrhages of Pregnancy and Parturition will be discussed. The subject for full congress will be Serum and Vaccine-Therapy. All the special sections are being well filled. The proposals for autonomy for the Australian branches of the British Medical Association will be considered. So far as present indications go these will be favourably received, although New South Wales has always opposed any move in such a direction in former years.

Cancer Cure.

About six years ago the procedure of a notorious cancer-curer named Davis was made the subject of much newspaper correspondence. His claims were championed by Sir John Madden, Chief Justice of Victoria, and as a result of this support the then Premier granted a board of inquiry into the alleged cure. This was composed of medical men and laymen in about equal proportions and presided over by Dr. W. P. Norris, chairman of the Board of Public Health. The committee has just presented its report, in which it is stated that the preparation was an arsenical one, and that in no instance had it cured cancer or fulfilled the claim made by its proprietor. In addition, the committee considered that in some instances its use had entailed unnecessary suffering. The committee also made some suggestions for the restriction of unqualified practice by cancer-curers.

Federal Quarantine.

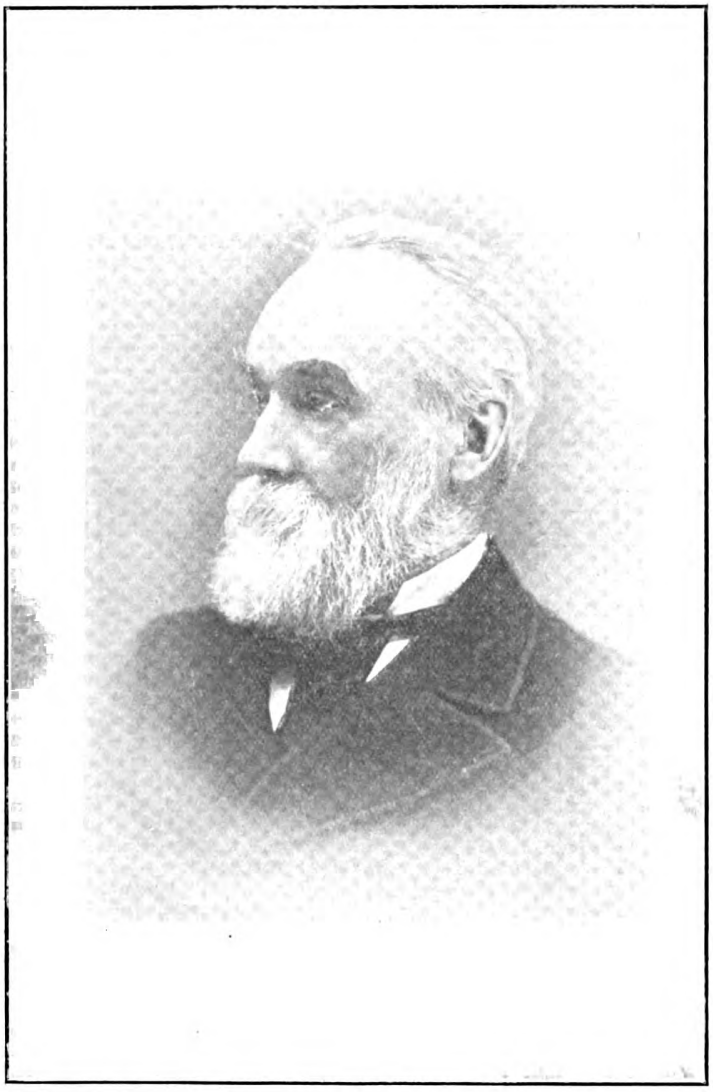
A new post as assistant medical officer has been created by the Federal Government in the Department of Quarantine at a salary of £650 per annum. It has been filled by the appointment of Dr. J. H. L. Cumpston, who was assistant medical officer in the Western Australia Health Department, and is a graduate of the University of Melbourne. Dr. Cumpston will have charge of the department during the absence on leave for six months of Dr. Norris, the Inspector-General.

Sept. 2nd.

Obituary.

JOHN HUGHLINGS JACKSON, M.D. ST. AND., F.R.C.P. LOND., LL.D., D.SC., F.R.S.,

CONSULTING PHYSICIAN TO THE LONDON HOSPITAL AND TO THE NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC.



Dr. John Hughlings Jackson, whose death occurred on Saturday, Oct. 7th, at his residence, 3, Manchester-square, London, was a Yorkshireman. He received his early medical training by acting as an apprentice in York and attending the York Medical and Surgical School, where Dr. Shann, physician to the dispensary, lectured on anatomy and physiology, and Mr. J. Milner superintended the dissecting. The school, though small, was a good one, and Jackson was well grounded when he proceeded to St. Bartholomew's Hospital. From this hospital in the space of a few months he qualified as M.R.C.S. Eng. and L.S.A. Lond. This was in 1856, and for a short time he returned to York as resident medical officer to the dispensary, but in 1859 he began that connexion with the London Hospital which was so fruitful in opportunities of work for him, and has redounded so much to the honour of the hospital, for in that year he was appointed lecturer in pathology and morbid anatomy, and also lecturer on histology and the microscope in the summer session. He owed these appointments to a great extent to the introduction of Sir Jonathan Hutchinson, whose interest in him was partly due to the fact that both received their early medical education at the York School. In 1860 he took the M.D. degree at the University of St. Andrews and in the following year was admitted a Member of the Royal College of Physicians of London. He was appointed assistant physician at the London Hospital and lecturer on physiology at its medical school in 1864. Even at that time he was recognised as a neurologist of mark, for we find him coupled with J. S. Ramskill and C. B. Radcliffe as an original member of the staff of the National Hospital for the Paralysed and Epileptic, to which hospital he became in due course full physician and consulting physician. In 1872 he became full physician at the London Hospital, passing on to the consulting staff in 1894. Occasion was taken of his retirement from the active staff to present him with his portrait in oils and a silver ewer and stand from his colleagues of the medical and surgical staff and numerous friends both at home and abroad, "in recognition of their esteem and admiration of his great services to the London Hospital Medical College, his distinguished position in the profession, and the advances he has effected in medical science by his laborious investigation and profound insight into diseases of the nervous system." Sir James Paget, in making the presentation, remarked on the fact that Jackson and Jonathan Hutchinson were among the first students he had taught, and he dwelt on the constant effort of Jackson to bring all clinical and scientific facts into harmony for the practical good of the patient. He laid special emphasis on Jackson's fruitful researches into the localisation of brain function, which, he said, had "given lucidity to physiology and guidance to surgery." Dr. Stephen Mackenzie remarked that Sir Jonathan Hutchinson had told him that the "greatest work he had ever done was to discover Dr. Hughlings Jackson." In 1868 Dr. Jackson was elected to the Fellowship of the College of Physicians, and in the same year he delivered the Croonian lectures of the College, taking as his subject the Evolution and Dissolution of the Nervous System. These

lectures were published in THE LANCET at a subsequent date. In 1869 he delivered the Goulstonian lectures on Certain Points in the Study and Classification of Diseases of the Nervous System, which were published in THE LANCET of February and March of that year. In 1872 Dr. Jackson delivered the Hunterian Oration, in which he discussed the question of education in its widest sense, pointing out the impossibility of preserving the artificially abrupt separation commonly made between mind and body. As physiologists, he said, we were concerned with physiological phenomena, with coördinations of impressions and movements of different orders, and not with memory, will, and the like. He pointed out that such coördinations were experimented on for us by disease, and from these experiments we might hope ultimately to obtain a knowledge of such physiological phenomena in their entirety. In 1877 he delivered the annual oration before the Medical Society of London on Ophthalmology in its Relations to General Medicine (THE LANCET, May 12th, 1877), a subject which served him also in 1890 for his presidential address to the Ophthalmological Society of the United Kingdom (THE LANCET, Oct. 26th, 1890); and in 1879 the Diagnosis of Epilepsy was the topic of a series of lectures given by him before the Harveian Society.

In 1885 he delivered the Bowman lecture before the Ophthalmological Society, on Ophthalmology and Diseases of the Nervous System, which was published in THE LANCET of November of that year. In 1889 he delivered the address in medicine at the Leeds meeting of the British Medical Association on the Comparative Study of Diseases of the Nervous System—a subtle address on those obscure relations of evolution to medicine, regarding which the profession was then, as now, groping towards the light, assured, however, that the day of fuller illumination is not far distant. In 1890 he was Lumleian lecturer, and took for his subject Convulsive Seizures, a subject that he had made peculiarly his own, for almost a quarter of a century had elapsed since the clinical and pathological study of convulsions due to gross local organic disease of the brain—now almost universally known as Jacksonian convulsions—had led him to enunciate the doctrine that the Rolandic region of the brain was "motor," and that in it the movements of the different parts of the body were represented. These lectures, which contained the latest views of his riper experience, were remarkable for their closeness of observation, clearness of argument, and the marvellous powers of induction of which they were the outcome. In 1897 Dr. Jackson delivered the first of the Jacksonian lectures, founded by the Neurological Society in his honour. These lectures, on the Relations of Different Divisions of the Central Nervous System to one Another and to Parts of the Body, were published in THE LANCET of Jan. 8th, 1898.

His literary work was extensive, but solid and unpretentious rather than ostentatious. Much of his work is to be found in those of our columns devoted to hospital reports. In 1868 he contributed the article on Convulsions and Epilepsy to Vol. II. of "Reynolds' System of Medicine." In the same year was published his "Cases of Disease of the Nervous System in Patients the Subjects of Inherited Syphilis." An "Abstract of a Paper on the Psychology of Language" was published by him about this time. In 1869 he published a reprint of his address before the St. Andrews Medical Graduates' Association on Cases of Disease of the Nervous System in Patients the Subjects of Inherited Syphilis, in which he conveyed the lesson that hemiplegia, chorea, and other diseases of the nervous system might be traced to the influence of hereditary syphilis, even when the patient presented none of the usual signs of the disease. The study of the family history was insisted on by him as of the highest importance, as tending towards the establishment of a right clue whereby cases otherwise hopelessly unintelligible might be benefited by specific treatment. In 1870 he published "A Study of Convulsions," to which we make further reference, and in 1879 "Some Remarks on the Routine Use of the Ophthalmoscope in Cerebral Disease." But Jackson's best literary work was in the form of communications to periodical medical literature. These were numerous and always important, reporting his wonderfully acute clinical and pathological observations and drawing from them deductions that formed at once an introduction to, and an abstract of, the numberless physiological experiments that have since been carried out, many of the results of which have been incorporated in the ordinary medical creed. The pathological and physiological knowledge to which they, together with the work of Ferrier, Schäfer, and others, were the prelude, have had as their sequel the brilliant surgery which in this country is identified with the names of Macewen and Horsley. Many of the more important of these communications appeared in our columns, as, for example: On a Case of Disease of the Posterior Columns of the Cord—Locomotor Ataxy (with Mr. Lockhart Clarke) (THE LANCET, June 10th, 1865); Clinical Remarks on Emotional and Intellectual Language in Some Cases of Disease of the Nervous System (THE LANCET, Feb. 17th, 1866); on Anatomical and Physiological Localisation of Movements in the Brain (THE LANCET, January, February, and March, 1873); a lecture on Softening of the Brain (THE LANCET, Sept. 4th, 1875), in which the precision of thought and language and the strict adherence to that only which is justified by clinical and pathological observation, which formed always such a valuable part of Dr. Jackson's treatment of a question, were very noticeable (in this lecture Jackson called attention to the frequent misuse of the term "softening of the brain" in cases which were really cases of nervous exhaustion, remediable by common-sense measures); On Nervous Symptoms with Ear Disease (THE LANCET, March 24th, 1877); On Tumours of the Cerebellum (THE LANCET, Jan. 24th, 1880); lecture on a Case of Intracranial Syphilis (THE LANCET, Feb. 21st, 1880); On Aphasia with Left Hemiplegia (THE LANCET, April 24th, 1880); A Case Illustrating the Value of the Ophthalmoscope in the Investigation and Treatment of Disease (THE LANCET, June 12th, 1880); Lecture on Auditory Vertigo (THE LANCET, Oct. 2nd, 1880); Eye Symptoms in Locomotor Ataxia (THE LANCET, Dec. 18th, 1880); The Psychology of Joking (THE LANCET, Oct. 22nd, 1887), an interesting paper in which it is stated that, Dr. Johnson to the contrary notwithstanding, punning should not be despised. His last paper in our columns was published (in conjunction with Mr. Leslie Paton) on March 27th, 1909, On Some Abnormalities of Ocular Movements.

Some 16 years ago an index to his published writings, from 1861 to 1894 inclusive, was printed in the *London Hospital Gazette*. They reached the astonishing total of 202, and the list was not complete. The amazing fertility of his genius can, perhaps, best be appreciated when it is noted that in three consecutive years (1873 to 1875) no fewer than 40 contributions to neurology emanated from his study, many of them long and elaborate, but all reflecting that intellectual power and comprehensiveness of view at which the reader of to-day still marvels. The first paper, in addition to those in our own columns, of which there is a record is entitled "Cases of Reflex Amaurosis, with Coloured Vision," which appeared in the Royal London Opthalmic Hospital Reports for 1861. It was followed ere long by "Observations on Defects of Sight in Brain Disease," "On Ophthalmoscopic Examination during Sleep," and "On the Use of the Ophthalmoscope in Affections of the Nervous System," all in the same series of reports. Thus early was Dr. Jackson instrumental in popularising the use of the ophthalmoscope, the most valuable of all weapons in the neurologist's diagnostic armamentarium. In 1864 came "Loss of Speech with Hemiplegia on the Right Side," and "Loss of Speech: its Association with Valvular Disease of the Heart, and with Hemiplegia on the Right Side." These contributions appeared very shortly after the discoveries of Broca, and served to elaborate and substantiate the contentions of the French *savant*. In 1866 a paper was published entitled "Remarks on those Cases of Disease of the Nervous System in which Defect of Expression is the most striking Symptom," which merits attention, inasmuch as it contains proof that Dr. Jackson had observed the phenomena and fully appreciated the significance of what has come to be known as apraxia 34 years before Professor Liepmann published the account of a case which has become a classic in the study of that subject. In these early years, too, appeared observations on "Regional Palsy and Spasm," on "The Disorderly Movements of Convulsion," on "The Sequence of Spasm in Unilateral Convulsions," and on "A Study of Convulsions," in which his unerring clinical acumen and scientific

JOHN HUGHLINGS JACKSON, M.D., F.R.C.P., LL.D., D.SC., F.R.S.
(Reproduced from a photograph by Messrs. Maull and Fox.)

imagination led him to postulate the existence of a motor area in the cortex and of centres in that motor area, and to determine their arrangement—brilliant speculations which subsequently received complete corroboration by the experimental work of Fritsch, Hitzig, and Ferrier. Merely to scan the titles of the lectures (Croonian, Lumleian, Hunterian, Bowman, &c.), presidential addresses, communications, papers, and notes that constitute the record of these fertile years leaves on the mind an indelible impression of the indefatigable industry and catholicity of interest of him whose superlative genius was equalled by his modesty. On July 15th, 1893, there was published in THE LANCET the first of that delightful series of "Neurological Fragments" which continued to appear at intervals for many years—chips from the workshop of a master mind. In his later years Dr. Jackson was wont whimsically to remark that he was afraid the younger generation of investigators would "find him out," and he was "found out," but not in the sense that amused his fancy. The psychologist of to-day has adopted Dr. Jackson's hypothesis of "levels" in the central nervous system; the physiologist has established the truth of his views on the functions of the motor cortex and of the cerebellum; the clinician and the pathologist are reaping in many fields where he sowed.

We have said enough to indicate that by the death of John Hughlings Jackson English neurology has suffered a loss, the extent of which it would be difficult to exaggerate. His was a figure that never came prominently before the general public, and while by reason of his age and his unusually retiring disposition he had perhaps become even to many of the profession not much more than a name, to his friends and to neurologists generally he was the "Grand Old Man" of their affection and esteem. No less than half a century has elapsed since he first ventured as a pioneer into the unexplored region of clinical neurology, to illumine its recesses by an unparalleled series of researches, conducted with unflagging zeal and enthusiasm, and animated by a rare scientific temper. Many of these researches culminated in discoveries which made his name familiar wherever medicine is taught the world over, but it is not merely because the present generation of the medical profession has entered into the fruit of these labours that he was regarded as the Nestor of neurology. The affection cherished for him by all who enjoyed the inestimable privilege of working with him as colleagues or pupils was no less striking than the unanimity with which his neurological genius was reverenced. Not a few whose names are as familiar to-day in foreign medical schools as his own were proud to call him their master. To come into close contact with that philosophic mind was to discover that discussions were somehow raised to its own high level, and that minuteness of detail could be combined with breadth of principle without either being sacrificed. It is because the modern student of scientific neurology was taught by Dr. Jackson how to think and how to work that the extent of his indebtedness cannot be readily estimated.

We may well close this notice with a few words from one of his pupils which show vividly what an admirable teacher and master Hughlings Jackson was. Dr. F. J. Smith writes: "The death of Hughlings Jackson takes me back in memory to the days when I first clerked under him in the very early 'eighties' of last century, when he had already gained great renown as a (perhaps the) leading neurologist, and consequently excited most reverential awe in the minds of us students, to whom his powers of diagnosis seemed little short of marvellous. We loved to go round with him because we felt that what he told us was true and was the outcome of real clinical observation, coupled with sound deduction, and not a mere quotation from others; for, indeed, we could find but little in our text-books that could compare with his teaching, or, rather, with which we could test his words. This must have been our reason, though, perhaps, we never admitted it to ourselves, for it would be idle to suggest that he talked freely, or in what would now be considered the correct fashion; we had from him no detailed results of examination of spinal fluid, no occult views on the precise methods by which nerve degeneration occurred, nor upon the precise meaning to be attached to every detail of a microscopic field; but we did get a knowledge of how to test reflexes, and of the significance to be attached to their increase or decrease, and of how to differentiate between their real and their apparent alterations. How we relied, too, upon his opinion as to whether optic neuritis was or was not present! In those days the ophthalmoscope was almost a novelty, and it became our ambition (never fulfilled by the way) to discover optic neuritis before Jackson did, and to draw his attention to its earliest appearance. It was, I think, by his appreciation of these our endeavours to tell him something we had discovered, that he attracted our love as well as our admiration, for it never could be said that his teaching or manners to us were attractive in the showy sense of the word. It has given me the keenest pleasure in later years to find how little I have had to unlearn that Jackson taught me, and to perceive how little inclined even modern neurologists are to sneer at anything he ever said or wrote; and frequently enough I have had the delight of telling some of them that they have only just re-discovered what Jackson had told us five and twenty years ago. Of his personal character I can say but little. We were too far removed in age to ever have been intimate, but the little I can say is that I never knew Jackson to do or say an unkind word to anybody; he had the modesty which only belongs to true genius, and when we approached him with some fancied discovery he never made one 'feel small'—rather did he profess his own ignorance of the point in question and give us the joy of believing we had helped him, though inwardly he must have chafed a little, I think, for he had to listen, doubtless, to much nonsense. To me Jackson will always remain as the greatest original I ever knew, for there was little foundation laid by others upon which to build. He has left a monument indeed for others perhaps to gild, but scarcely to improve its architecture."

Dr. Jackson had many honours conferred on him. He received the honorary degree of LL.D. from the Universities of Glasgow and Edinburgh, that of D.Sc. from the University of Leeds, that of M.D. from the University of Bologna, and the honorary Fellowship of the Royal College of Physicians of Ireland. He was, of course, a Fellow of the Royal Society. He was also a corresponding member of the Royal Academy of Medicine of Belgium. In 1907 a marble bust of him was placed in the National Hospital for the Paralysed and Epileptic.

JOSEPH BELL, M.D. EDIN., F.R.C.S. EDIN., J.P., D.L.,

CONSULTING SURGEON TO THE ROYAL INFIRMARY EDINBURGH, ETC.

WE regret to announce the death of Dr. Joseph Bell, which occurred at his residence Maurice Wood, Milton Bridge, Midlothian, on Wednesday, Oct. 4th. Dr. Joseph Bell's distinguished surgical career was very intimately associated with Edinburgh. The eldest son of Benjamin Bell, an Edinburgh surgeon, he was educated at Edinburgh Academy and the University of Edinburgh, and did his clinical work as a medical student at the Edinburgh Royal Infirmary. Having taken the degree of Doctor of Medicine in 1859 he served in all the junior posts at the infirmary. In 1863 he took the Fellowship of the Royal College of Surgeons of Edinburgh, was for a time demonstrator of anatomy in the University, and was elected assistant surgeon to the Royal Infirmary in 1871. He had not long to wait for a vacancy as full surgeon, and in the meantime had been appointed surgeon to the Edinburgh Eye Infirmary shortly after qualification, and later surgeon to the Royal Hospital for Sick Children, Edinburgh. Upon the staff of all of these institutions he served with distinction for the full term of office, and was duly elected consulting surgeon in each case. His private practice grew with his public appointments. At the University of Edinburgh he held several educational appointments and examinerships.

He was not only an extremely skilful surgeon, but carried, as is well known, the art of diagnosis very far by his extraordinary faculty of detecting the ordinary routine of his patient's careers or the environments in which they lived. Bell was not that dangerous person the "lightning diagnostician," but, having behind him a very full surgical equipment, he was able to reinforce his scientific knowledge by a wide familiarity with the ordinary conditions of life, and an almost uncanny intuition of the part which those conditions had played in the healths and lives of any man, woman, or child who happened to come before him. By this faculty he became famous throughout the world owing to the accidental circumstance that Sir Arthur Conan Doyle, when completing his medical education in Edinburgh some 30 years ago, worked under Bell, and was so

impressed by the display of his chief's deductive faculties that he was led to create his famous hero Sherlock Holmes. Sir Arthur Conan Doyle has recorded a typical episode, which occurred in the out-patient department of the infirmary, when a new patient was told, without being questioned, that he was a soldier, a non-commissioned officer, who had served in the West Indies. The speech then made by Bell was exactly similar to the many speeches with which the great detective confounds the not over-ready wit of his friend Watson, and it is easy to see how the dramatic side of Joseph Bell's highly developed gifts of observation led to the fashioning of Sherlock Holmes.

Joseph Bell was a successful though not very prolific author, but for no less than 23 years edited the *Edinburgh Medical Journal* with conspicuous ability. A small manual upon surgical operations, a subject on which he had lectured at the University of Edinburgh, ran through seven editions, and "Some Notes on Surgery for Nurses" achieved almost as great a success. He was a Fellow of the Royal Society of Edinburgh and a Deputy Lieutenant of the county. His wife was the daughter of the Hon. James Erskine Murray, but he had for a long time been a widower.

LOUIS STROMEYER LITTLE, B.A. LOND., F.R.C.S. ENG., M.D. KIEL,

LATE SURGEON TO THE LONDON HOSPITAL AND TO THE SHANGHAI GENERAL HOSPITAL.

AFTER a long illness the death of Louis Stromeyer Little took place at his residence at Bletchingley, Surrey, on Oct. 4th. Mr. Little, who was 70 years of age, was a student at the London Hospital, where he subsequently held the posts of lecturer in anatomy, curator of the museum, and surgeon to the hospital. He took the M.R.C.S. Eng. in 1862, and proceeded to the Fellowship four years later, while he graduated in Arts at the University of London. He also took the degree of Doctor of Medicine in the University of Kiel, and held surgical appointments at the London National Orthopædic Hospital and at St. Mary's Dispensary for Women and Children. In or about 1876 he went to Shanghai in China, where he resided for nearly 20 years, and was surgeon to the Shanghai General Hospital. He then returned to England and lived in retirement at Bletchingley in Surrey.

During the war in 1864 Little was present at the campaign in Schleswig from February to May in that year, doing much good work in tending the wounded, Prussians and Danes, over 2000 in number. In his "Notes on the Campaign" Dr. Little made some interesting observations on his own experiences and those of the great Esmarch with whom he worked. He was buried at Bletchingley.

GEORGE THOM, M.R.C.S. ENG., L.S.A., J.P.,

CONSULTING SURGEON TO THE ROYAL ALBERT HOSPITAL DEVONPORT.

Mr. George Thom died at his residence, 1, Clarendon-terrace, Devonport, on Oct. 8th, in his sixty-sixth year. He received his medical education at King's College Hospital, London, and took the M.R.C.S. and L.S.A. qualifications in 1870. He was shortly afterwards appointed resident medical officer at the Royal Albert Hospital, Devonport. He resigned this post after six years' service, and commenced practice at Devonport. He was for many years on the honorary staff of the Royal Albert Hospital, and at the time of his death was consulting surgeon to the institution. Mr. Thom had a large practice in the "Three Towns," where he was most highly respected. He was one of the oldest borough magistrates for Devonport, and attended to his magisterial duties as recently as Oct. 4th. He had been in failing health for some time, but had continued his professional work up to a few days before his death. He will be much missed in Plymouth, Devonport, and Stonehouse, and great sympathy is felt there for his widow, daughter, and three sons, one of whom is a member of the medical profession.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. Julius von Michel, professor of ophthalmology in the University of Berlin, from cardiac disease, at the age of 68. He had been somewhat unwell for a good while, but, notwithstanding reports to the contrary, proposed to continue to carry on the active duties of his chair. His student days were passed in Würzburg and Zürich. Before the Franco-German war, in which he took part, he was assistant in the Zürich ophthalmic clinic under Professor Horner. Subsequently he went to Leipsic, where he worked under Coccius, Ludwig, and Schwalbe, and afterwards became professor of ophthalmology successively in Erlangen, Würzburg, and Berlin, where he followed Professor Schweigger. He published a number of papers, besides a large text-book on the eye, and edited a well-known ophthalmological journal.—Dr. Starling Loving, professor of medicine in the Starling-Ohio Medical College.—Dr. Meyer-Steinegg, *privat-docent* in the University of Jena.—Dr. Mitscherlich, sanitary councillor of Charlottenburg.

Medical News.

EXAMINING BOARD IN ENGLAND BY THE ROYAL COLLEGES OF PHYSICIANS OF LONDON AND SURGEONS OF ENGLAND.—At the Second Professional Examination in Anatomy and Physiology held on Sept. 28th and 29th, and Oct. 2nd and 3rd, 73 candidates presented themselves, of whom 40 were approved and 33 were rejected. The following is a list of the successful candidates:—

Charles Layton Balkwill, Birmingham University; Otto Barkau, B.A. Oxon., Oxford and Freiburg Universities; Dhirendranath Basu, Calcutta and Middlesex Hospital; William McHuchison Binning, University College; Cecil Bluett, London Hospital; Geoffrey Alwyn Gershom Bonser, B.A. Cantab., Cambridge University and St. Thomas's Hospital; Frederick Wyndham Chamberlain, Middlesex Hospital; Edwin Lionel Christoffelsz, Ceylon Medical College and London Hospital; John Edgar Davies, Guy's Hospital; William Sadgun Desai, L.M.S. Bombay, Bombay University; Alma Percy Ford, London Hospital; Frank Brayshaw Gilhespy, University College; Evan Williams Griffith, University College, Cardiff; Frank Arnold Gunesekera, L.M.S. Ceylon, Ceylon Medical College; Donald Herbert Hargrave, London Hospital; Joseph Francis Holmes, Calcutta and Charing Cross Hospital; Oswald Ryle Horwood, M.A. Cantab., Cambridge University and London Hospital; Arthur Maddock Jones, Charing Cross Hospital; James Phillips Jones, Guy's Hospital; Walter Hewitt Jones, St. Mary's Hospital; Joseph Georges L'Etang, St. Bartholomew's Hospital; Desmond Manus MacManus, Guy's Hospital; Samuel Mallinick, Halle University and London Hospital; George Frederick Meinertzhagen, St. Bartholomew's Hospital; Arthur Rennie Muir, Cardiff and University College; Henry Felix Mullan, London Hospital; Kenneth Montague Nelson, St. Mary's Hospital; Walter Justice Paramore, University College; Leonard Robert Pickett, Guy's Hospital; John Wootton Rammell, London Hospital; Cecil Arthur Robinson, St. Mary's Hospital; Gordon Wilfred Ritchie Rudkin, University College; Henry Christmas Samuel, Ceylon Medical College and Middlesex Hospital; Mohammed Sharaf, Cairo and St. Mary's Hospital; Cuthbert Shaw-Crisp, St. Mary's Hospital; Alan Edward Staffurth, Cambridge University and St. Thomas's Hospital; George Sydney Stathers, St. Bartholomew's Hospital; Herman Crowther Viehoff, Liverpool University; Philip Pennefather Warren, London Hospital; and Ernest Jenner Wright, St. Mary's Hospital.

At the quarterly examination in Practical Pharmacy held on Oct. 5th the following candidates were approved:—

Malcolm Barker, L.D.S. Eng., Charing Cross Hospital; William Fletcher Barrett, Birkbeck College and private study; Alexander William Charles Bennett, St. Thomas's Hospital; Ellis Campbell Bowden, London Hospital; Robert Graham Brown, London Hospital; Richard Challoner Cobbe Clay, Westminster Hospital and private study; Charles Frederick Constant, Guy's Hospital; George Malcolm Coope, Manchester University; Edward Dance Fountain, St. Mary's Hospital; Henry Charles Coutts Hackney, King's College Hospital; Arthur Edward Huxtable, Charing Cross Hospital; Henry Barry Hyde, St. Thomas's Hospital; Thomas Hitchings James, London Hospital and private study; Kenneth John Taylor Keer, Guy's Hospital; William Morgan Langdon, Guy's Hospital; James Lafayette Lauder, Guy's Hospital; Gerald Laurence, Middlesex Hospital; Edmund Thomas Howard Lea, Westminster Hospital and private study; Frederick Martin Lipscomb, King's College Hospital; Eustace Fernando Llarena, Guy's Hospital; Bryen McDermott, Guy's Hospital; Maurice Mackenzie, London Hospital; William Frank Morgan, London Hospital; William Henry Parr, London Hospital; Claud John Burgoyne Pasley, Westminster Hospital and private study; James Remers, Manchester University; Herbert Thomas Retallack-Moloney, London Hospital; Denys Revell Reynolds, St. Bartholomew's Hospital; Henry Charles Rigg, Charing Cross Hospital; Harold Robinson, Manchester University; Maitland Scott, Guy's Hospital; Ambrose Huntington Warde, St. Thomas's Hospital; and Nathan Judah Wigram, Sheffield University.

UNIVERSITY OF GLASGOW.—The following have passed the First Professional Examination for the degrees of M.B. and Ch.B. in the subjects indicated (B., Botany; Z., Zoology; P., Physics; C., Chemistry):—

Robert Aitken (Airdrie) (B., P.), William Dick Allan (B., P.), John Alston (B., P.), William Baird (B., P.), William Barras (B., P.), Monindra Nath Bhattacharjie (B., P.), Thomas Blackwood (B., P.), Robert Mitchell Stewart Boyd (Z., C.), William Ernest Boyd (Z.), John Bradford (Z., C.), John Buchanan (P., C.), Donald Ronald Colin Cameron (B., Z., P., C.), Dugald Stewart Campbell (B., P.), John Ferguson Campbell (B., P.), William Campbell (B., P.),

Thomas Watson Carstairs (Z., P.), Joseph Chalmers (B., P.), Allan La Barte Clark (Z., C.), Douglas Hamilton Coats (B., P.), John Connal (B., C.), William Kerr Connell (B., P.), Alexander Findlay Cook (B., P.), Archibald Shankland Cook (B., P.), Walter Gow Cook (B.), Robert Stobo Crawford (B., Z., P., C.), Henry Paterson Crow (Z., C.), John Freeland Cunningham, M.A. (B., Z., C.), William Cunningham (B., P.), John Williamson Dalglish (B., P.), Ronald Stevenson Dickie (B., Z., P.), John Dunbar (B., P.), Ernest M'Murchie Dunlop (B., Z., P., C.), James Jackson Finlay (Z., C.), Thomas Finlay (B., Z., P.), Thomas Fleming (B., P.), George John Fraser (C.), Matthew Mair Frew (B., P.), Walter Weir Galbraith (C.), Leonard Woodburn Gemmell (C.), John Albert Frank Gibson (Z.), Robert Stuart Gibson (Z., C.), Norman William Gilchrist (P.), Robert Kinnear Hay Gillespie (B., Z., P.), Colin Campbell Blair Gilmour, M.A. (B.), John Gray Gilmour (B., Z., P.), John Glaister (B., P.), Peter Fife Auchinachie Grant (B., P.), David Heard (B., P.), Arnot Campbell Hepburn (B., Z., P.), William Allan Higgins, M.A. (B., P.), Arthur Robert Hill (B., P.), Oswald Johnston (B., P.), John Crawford Knox (B., C.), Robert Kyle (Z.), Robert Milne Lang (B., P.), Hugh Brown Lawrie (C.), James Alexander Leiper (B., Z., P., C.), Peter Young Lyle (B., Z., P.), Hugh Lawrence M'Cormick (B., Z., P.), Patrick M'Diarmid (B., P.), Robert William MacDonald (P.), James Wallace Macfarlane (B., P.), John Mandeville Macfie (B., P.), Arthur Daniel Clark M'Gowan (P.), Archibald M'Innes (B., Z., P., C.), John MacInnes (B., Z., C.), Alexander Fraser M'Intosh (B., P.), James MacAlister Mackintosh (B., P.), Keith Stuart Macky (B., P.), George Maclean (P., C.), Peter Donald MacLean, M.A. (P.), Donald Macphail Macmillan (Z., P.), Frederick Robertson Martin (B., P.), John Campbell M'Intyre Matheson (B., P.), Alexander M'Callum Millar (B.), William Duff Miller (B., P.), John Desmond Milligan (B., P.), Peter Orr Moffat (C.), Frederick William Morrison (B., Z., P., C.), William Watson Morrison (B., P.), Alexander Morton (B., P.), John Hughes Murray (B., Z., P.), Thomas Fraser Noble (P.), Michael O'Callaghan (B., Z.), James Alphonsus O'Connor (B., P., C.), Robert Lamont Ormsby (B., P.), Arthur William Panton (B., P.), John Roberts Pate (Z.), James Alexander Paterson (B., Z.), Thomas Smith Paterson (B., Z., P., C.), James Herbert Paul, M.A. (B., P.), William James Poole (B., P.), William Burns Primrose (B., C.), Hugh Quigley (P.), Robert Scott Reid (B., P.), James Gordon Rennie (P.), John King Rennie (B., P.), James Richardson (B., P.), Kenneth M'Alpin Ross (B., Z., P.), Andrew Stenhouse (B., Z., P.), Douglas Stuart Stevenson (B., Z., P.), Pat Adam Stewart (B.), William Mitchell Stewart (B., P.), Archibald Sutherland Strachan (B., C.), John Brunton Sweet (B., Z.), Clement Bennet Templeton (B., P.), Robert Taylor Todd (B., P.), John Lawrence Torley (B., Z., P.), Adrian Johannes van der Spuy (B., P.), George Turnbull Walker (B., P.), Robert Richmond Waters (B., P.), John Dalglish Watson (B., P.), William James Cunningham Watt (B., P.), Robert Smellie Weir (B., P.), Thomas M'Skimming Wilson (B.), and John Thomas Wylie (B., P.)

Women.—Christina Blair Buchanan (B., P.), Maud Christine Cairney (B., P.), Ann Kelly Cormack (B., Z., P., C.), Jane Beattie Davidson (B., Z., P.), Jessie Crawford Gilchrist (B., P.), Janet Fraser Henderson (Z., P.), Helen Isobel Winifred Kerr (B., Z., P., C.), May Constance Broughton Leigh (B.), Dorothy M'Cubbin (B., P.), Margaret Jane Maclachlan (B., P.), Effie Cowan M'Vie (B., C.), Elizabeth Stewart Martin (B., P.), Mary Anderson Noble (B., P.), Mary Helen Routledge (B., P.), Mary Scott (B., Z.), Ishbel Mary Sinclair (Z.), Jane Stalker (B., P.), Margaret Ann Hendry Stewart (B., Z., P.), Isabel Stirling Thomson (B., P., C.), Marion Baillie Darling Wilson (B., P.), and Isabella Henrietta Younger (P.).

The following passed with distinction in the subjects indicated:—

Botany, Zoology, Physics, and Chemistry.—Ernest M'Murchie Dunlop.

Botany and Physics.—John Mandeville Macfie, Jane Stalker, and John Thomas Wylie.

Botany.—Donald Ronald Colin Cameron and John Crawford Knox.

Zoology.—Henry Paterson Crow.

Physics.—John Alston, Thomas Blackwood, Christina Blair Buchanan, William Cunningham, John Dunbar, Dorothy M'Cubbin, Frederick William Morrison, Robert Smellie Weir, and Marion Baillie Darling Wilson.

Chemistry.—Effie Cowan M'Vie, William Burns Primrose, and Archibald Sutherland Strachan.

The following have passed the Second Professional Examination for the degrees of M.B. and Ch.B. in the subjects indicated (A., Anatomy, P., Physiology, M., Materia Medica and Therapeutics):—

Douglas Kinchin Adams, M.A. (M.), Alexander Baird (M.), Henry Stanley Banks, M.A. (M.), Archibald M'Allister Blackwood (A., P.), Abraham Blashky (A., P.), John Smith Knox Boyd (M.), James Law Brownlie (A.), Samuel Bryson (P.), Alexander Grahame Buchanan (P.), Edmund Tytler Burke (A.), John Joseph Burke (A.), John Cameron (A.), William Leonard Cassells (M.), Benjamin Cohen (M.), George Gibson Cooper (M.), Thomas Muir Crawford (A., P., M.), Lawrence Cromble (P.), William Cullen (M.), Gabriel Daniel de Kock (A., P.), Alexander Dick (M.), John Nairn Dobbie (A.), Joseph Dunbar (A., M.), Walter Elliot Elliot, B.Sc. (A., M.), William Campbell Fleischmann (P., M.), James Bryan Fotheringham (P.), William Fraser (P., M.), Ian Grant (P.), John Galloway Hendry (A., P., M.), Thomas Cameron Houston (M.), William Yuill Jamieson (A. M.), William Joseph Brown Lavery (A.), Alexander Lindsay (A., P.), James Walter M'Donald (P., M.), John M'Ghie (A., M.), James Graeme M'Kinna (P.), Kenneth Norman MacLean (M.), Neil MacLeod (A., P.), Robert Martin M'Minn (M.), Ewen Stewart Macphee (A., M.), William Strelley Martin, M.A. (P., M.), John Park Mathie (A.), Thomas Spence Meighan (M.), Archibald Underwood Millar, M.A. (A., P., M.), Thomas Augustine O'Brien (A., P.), James Leslie Ruthven Philip (A., P., M.), Adam Rankine (M.), David Reid Eccles Roberts (M.), Stewart Dewar Robertson (M.), Neil Islay Sinclair (A.), William Robertson Snodgrass, M.A. (A., M.), John Fraser Steven, M.A. (P.), Henry Stewart, M.A. (A.), Ronald Stewart (M.), William Ballantine Stewart, (P., M.), Henry Currie Watson (M.), James Whiteside (A., P.), Alexander Sweet Wilson (A., P.), Andrew Morton Young (M.), and John Miller Young (M.).

Women.—Cecilia Small Turnbull Anderson (M.), Grace Gillies Turnbull Anderson (A., P.), Margaret Jarvey Brown (A., P.), Ethel Crawford, (A., P., M.), Lillias Beverley Hardie (M.), Mary Pringle Hislop (M.), Annie Rankine M'Kail (A., P., M.), Sarah Anderson Jamieson Rankine (M.), Margaret Walker (P.), and Josephine Adelaide Woods (M.).

Mr. John Smith Knox Boyd passed with distinction in the subject of Materia Medica and Therapeutics.

The following have passed the Third Professional Examination for the degrees of M.B. and Ch.B. in the subjects indicated (P., Pathology; M., Medical Jurisprudence and Public Health):—

John Campbell Hill Allan (M.), James Angus (P., M.), Richard Archibald Barlow, B.Sc. (P., M.), Samuel Blumenfeld (M.), Vynne Borland (P., M.), James Wilson Burton (P., M.), Norman Cameron (M.), George Wilson Clark (P., M.), Robert Craig, M.A. (M.), George Dalziel (P., M.), James Henry Dible (M.), Philip Figdor (M.), Adolph Robert Hanns Geyer (P.), Leopold Glushak (M.), Cecil William Fletcher Greenhill (P., M.), James M'Farlane Grier, M.A. (P., M.), John Ferguson Hutton, M.A. (P., M.), Thomas Pollock Inglis (M.), Andries Johannes Joubert (M.), Charles Joseph Hamilton Kirk (P.), Robert Aim Lennie (P.), John Aloysius M'Connochie (M.), John Henry Magoveny (M.), William Montgomery (M.), Kenneth Duncan Murchison (P.), Arthur Alexander Murison (M.), Andrew Neilson, (M.), Andrew Peden (P.), James Purdie (M.), James Francis Quigley (Lambhill) (P., M.), David William Reid (M.), John Ritchie Richmond Ritchie (M.), Alfred Leopold Robertson (M.), Edwin Robertson (P., M.), James Gordon M'Gregor Robertson (P., M.), James Inglis Robertson (M.), Archibald Watson Russell (M.), John Finlayson M'Gill Sloan (P.), Hendrik Cornelius van der Wat Smit (M.), James Anstruther Smith (P.), John Kenneth Smith (P., M.), Alexander Robert Bogue Soga (P., M.), John Alexander Stewart (M.), William Patrick Andrews Stewart (P., M.), William Rowland Taylor (P., M.), Ernest Graham Young Thom, M.A. (P., M.), Edward Napier Thomson (M.), Angus Walker (M.), Thomas Walmsley (M.), Matthew White, M.A. (P., M.), Frederick John Whitelaw (P., M.), and William Brockie Wilson (M.).

Women.—Jane Kerry M'Elroy Hunter (P.), Mary Anne Kirk (P., M.), and Janet Morris Walker (M.).

Mr. William Brockie Wilson and Miss Mary Anne Kirk passed with distinction in the subject of Medical Jurisprudence and Public Health.

The following have satisfied the examiners in the Fourth (Final) Professional Examination for the degrees of M.B. and Ch.B.:—

Mark James Aitken, Alexander John Archibald, Thomas Stewart Barrie, William Egon Halman Beard, James Elliot Black, John Bower, David Sands Brough, Angus Dugald Buchanan, William Murdoch Buchanan, Charles Cameron, M.A., John Campbell, George Cochrane, M.A., James Alphonsus Joseph Conway, Robert Corbett-Corbett, James Findlay, M.A., Leander Lowrie Fyfe, William Gordon Goudie, John Radcliffe Grice, M.A., Charles Hope Haddow, James Stewart Hall, Daniel Christopher Hayes, John Richmond Herbertson, Andrew Gray Holms, Isabel Inglis, James Johnstone, Alexander Kirkhope, John M'Callum Lang, Norman M'Farlane, Barbara Macgregor, Murdo Mackinnon, William Wyllie MacNaught, Katherine Stewart Macphail, Farquhar Matheson, James Matheson, John Mitchell, Andrew Muir, Ellen Brown Orr, Hugh Paterson, James Eric Paterson, Henry Charles Deans Rankin, Hugh Young Riddell, William Logan Scott, Christina Hamilton Shearer, Alexander Hunter Sinclair, James Smith, Isabel Jane Stark, James Alexander Hamilton Telfer, William Tudhope, James Lachlan Ure, Gordon Alexander Valentine, Hugh Ferguson Watson, L.R.C.P., Archibald Wilson, Douglas Wilson, and Walter Percy Yates.

The following passed with distinction in the subjects indicated:—

In (*a*) Surgery and Clinical Surgery, (*b*) Practice of Medicine and Clinical Medicine, (*c*) Midwifery: Charles Cameron, M.A. In (*a*) Surgery and Clinical Surgery, (*b*) Midwifery: David Sands Brough. In (*a*) Practice of Medicine and Clinical Medicine, (*b*) Midwifery: Farquhar Matheson and James Eric Paterson. In Midwifery: Mark James Aitken, William Egon Halman Beard, John Bower, Robert Corbett Corbett, James Stewart Hall, Katherine Stewart Macphail, Ellen Brown Orr, Alexander Rae, and Henry Charles Deans Rankin.

FOREIGN UNIVERSITY INTELLIGENCE.

Berlin: Dr. Carl Keller, *Oberarzt* of the Gynæcological Department of the Charlottenburg Hospital, has been granted the title of Professor.—*Brussels:* Dr. E. H. Starling, Professor of Physiology in the University of London, has been elected Foreign Corresponding Member of the Belgian Royal Academy of Medicine.—*Catania:* Dr. F. Zangri has been recognised as *privat-docent* of Medical Pathology.—*Christiania* (centenary celebration): In addition to the names already announced the honorary doctor's degree has been conferred upon Sir T. Barlow (London), Sir W. Osler (Oxford), Dr. Bacceli (Rome), Dr. Bang, Dr. Gram, and Dr. Salomonson (Copenhagen), Dr. Golgi (Paris), Dr. Hammarsten (Upsala), Dr. Tigerstedt (Helsingfors), Dr. Kocher (Berne), Dr. Pawlow (St. Petersburg), Dr. Ramón y Cajal (Madrid), and Dr. Weichselbaum (Vienna).—*Freiburg:* Dr. Marx has been appointed temporarily in place of Dr. Killian to act as Professor of Laryngology. Dr. Hermann Determann, *privat-docent* of Medicine, and Dr. Adolf Oberst, *privat-docent* of

Surgery, have been promoted to Extraordinary Professorships.—*Genoa:* Dr. G. Moro has been recognised as *privat-docent* of Surgery and Dr. R. Carreras as *privat-docent* of Odontology.—*Gratz:* Dr. A. Wittek, *privat-docent* of Orthopædic Surgery, has been granted the title of Extraordinary Professor.—*Innsbruck:* Dr. Rudolf Schmidt of Vienna has been appointed to the chair of Medicine and Director of the Medical Clinic in succession to Dr. Ortner.—*Kiel:* Dr. Ludwig Bitter has been recognised as *privat-docent* of Hygiene.—*Lausanne:* Dr. Beitzke of Berlin has been offered and accepted the chair of Pathological Anatomy, which has been vacant since the death of Dr. Stilling.—*Modena:* Dr. I. Bruchi has been recognised as *privat-docent* of Surgery and Operative Medicine.—*Naples:* Dr. G. Ferulano has been recognised as *privat-docent* of Surgical Diagnosis.—*Padua:* Dr. G. Monzardo has been recognised as *privat-docent* of Operative Medicine.—*Parma:* Dr. E. Bertarelli has been promoted to the Ordinary Professorship of Hygiene.—*Pisa:* Dr. G. Gentili, Dr. S. Luschi, and Dr. F. Ravenna have been recognised as *privat-docenten* of Internal Pathology.—*Prague (German University):* Dr. E. J. Kisch, Professor of Balneology, has resigned.—*Rome:* Dr. Pietro Frascella and Dr. Filippo Lofaro have been recognised as *privat-docenten* of External Pathology.—*St. Louis (Washington University):* Dr. Ernest Sachs has been appointed Adjunct Professor of Surgery.—*Vienna:* Dr. Hugo Leischner has been recognised as *privat-docent* of Surgery.

SALARIES OF DISTRICT MEDICAL OFFICERS.—The Camberwell board of guardians have accepted the resignation of Mr. W. E. Morgan as district medical officer for the Camberwell district. The board met in committee, when the guardians came to the decision that in view of the number of cases they did not consider the remuneration at present paid of £100 per annum adequate for the post of district medical officer, and recommended an increase to £125 per annum, subject to the approval of the Local Government Board. At a meeting of the board on Oct. 5th Mr. S. Sayer proposed that the salary remain at £100. The late medical officer had been satisfied with that sum, and it was strange to offer an increased salary without any reason being given. It was for Mr. Morgan to say if the salary was too small, but he had never applied for an increase. It was the same amount they gave all their district medical officers when they commenced. There was something less than an hour's work in the morning, with only half-a-dozen cases to visit. It was an easily earned £2 a week. The guardians were increasing salaries all round, and he protested against it. Mr. C. E. Renouf, in seconding, said they treated their district medical officer very well when they gave him £2 a week. Only two guardians voted for the reduced salary, the proposal to grant £125 being carried.

ST. MARY'S HOSPITAL.—The annual dinner of the school was held at Princes Restaurant on Oct. 3rd, Mr. A. T. Norton, Master of the Apothecaries' Company, being in the chair. There were 152 present. After the loyal toasts had been honoured, the chairman rose to propose "St. Mary's Hospital and Medical School." He gave a vivid description of taking a country walk in his youth in the district now known as Paddington. There was a glorious wood in those days where the Great Western terminus now stands, and a creek meandered along the present Westbourne Grove. When he entered the hospital as a student there was no necessity for a preliminary examination, and two and a half years were considered sufficient to gain all the knowledge required to obtain the M.R.C.S. or L.S.A. The development of surgery he then traced from the time when one theatre and one afternoon a week were ample for a hospital of the size of St. Mary's, to the present day when several theatres in use every day, and sometimes all day, alone suffice for the needs of the hospital. Having described the conditions of 50 years ago he speculated on the possibilities of 50 years hence. Perhaps operations for appendicitis or perityphlitis would be unknown. The scope of serums and vaccines had still to be determined. He uttered a grave warning about the Insurance Bill. "Unless," he said, "it is altered to suit the medical man there will be a further falling off in the recruits of the profession." Mr. W. Austin Leigh (chairman of the hospital board) responded. He laid stress on the work of the hospital during the summer months. The three largest hospitals in the neighbourhood—Middlesex, St. George's, and Paddington Green—all being closed for considerable periods, the work was excessive, "and," he added, "we hope we will never again have to do the work of four hospitals during the hottest part of the year." Sir John Broadbent, also responding, pointed out the success of the hospital in gaining for the seventh year in succession one of the coveted gold medals of the London University, and also the gaining of the Middlemore prize awarded by the British Medical Association to Mr. C. W. G. Bryan. He drew attention to the falling off generally in the entrance of medical students. In spite of this falling off in numbers, in spite of provincial competition, and in spite of the Insurance Bill of Mr. Lloyd George, St. Mary's had already a considerably larger entry this year than last. Dr. J. O. Symes proposed "The Chairman" in an eloquent and sincere speech. "Mr. Norton's opinion was," he said, "pre-eminently a sound one, founded on wide experience, sound judgment, and keen powers of observation. Behind it all was a simple and great-hearted man." The chairman made an appreciative and sympathetic response.

PHLEBOTOMUS FEVER IN ITALY.—For many years during the months of June, July, and August in various provinces of Italy, especially in the north, a special form of epidemic fever has been observed. The characteristics of the epidemic are the suddenness of the onset and the rapidity of its diffusion. The disease is never fatal. The fever lasts for about 60 hours and leaves the patient very prostrated in mind and body for about a fortnight. The usual clinical picture is the following: an individual in good health is overcome by malaise, followed by frontal headache, pain in the limbs and in the loins; the fever reaches its highest point in some 12 hours, and then descends slowly without remissions and ceases in about 60 hours. The patients usually preserve appetite, but the tongue is white and the bowels are confined; in a few cases the tonsils or pharynx are reddened; occasionally there is epistaxis; the spleen is not enlarged; there is no albuminuria. A symptom present in almost all cases is a very marked and persistent redness of the face, such as one does not meet with in other diseases. Relapses are common. The infection is due to a virus which will pass through a Berkefeld filter. This virus is transmitted from man to man by the phlebotomus pappatasii, an insect that lives on human blood and is found in houses, especially in the bedrooms. The virus can remain active in these insects for ten days. To contract the disease numerous bites by these insects are necessary. The incubation period is from four to five days. (Annali di Igiene Sperimentale, Vol. XXI., Fasc. II., reviewed in Rivista Critica di Clinica Medica, XII., 38).

DONATIONS AND BEQUESTS.—The late Mr. Gibson, a former mayor of Newcastle, has, among other large bequests, left £2000 to the Newcastle Royal Infirmary.—By the will of the late Mrs. Charlotte Maud Barnato the testatrix bequeathed £1000 to the London Hospital (for the women's ward), and £500 each to the Cancer Hospital (for the women's ward), St. Mary's Hospital, Paddington (for the women's ward), the Samaritan Women's Hospital, Marylebone-road, the Children's Hospital, Paddington-green, the Middlesex Hospital (for the children's ward), the Hospital for Sick Children, Great Ormond-street, the Jews' Hospital and Orphan Asylum, and the Hospital for Women, Soho-square.—The late Mr. Albert R. T. Momber has by will bequeathed the following approximate amounts to the various institutions—viz., £2520 to the Governors of University College, London, upon trust to apply the income in maintaining a scholarship or scholarships for science; £2160 to University College Hospital; £1440 each to the London Hospital and the Queen-square Hospital, W.C.; £1080 to St. George's Hospital; £3600 equally between the Lister Institute, Chelsea, the Marine Biological Research Association, Plymouth, the Cancer Research Institution, and the Tuberculosis Research Institution; £720 each to the Royal Sea-Bathing Infirmary, Margate, the Hospital for Consumptives, Ventnor, the Royal Asylum for the Blind, Chelsea, the Home for Crippled Children, Chelsea, and the Frimley Sanatorium in connexion with the Brompton Hospital; and £180 each to Dr. Barnardo's Homes, the Malvern Rural Hospital, the Royal Free Hospital, Gray's Inn-road, the Royal Society for the

Protection of Birds, the Royal Society for the Prevention of Cruelty to Animals, and the Naples Society for the Protection of Animals.—Under the will of the late Miss Ellen Baker the Worthing Infirmary will receive £500.

SOCIETY OF TROPICAL MEDICINE AND HYGIENE.—A meeting of this society will be held at 11, Chandos-street, Cavendish-square, W., on Friday, Oct. 20th, at 8.30 P.M., when Dr. A. G. Bagshawe will read a paper on Recent Additions to our Knowledge of Sleeping Sickness.

THE PROPOSED ISOLATION HOSPITAL IN TORONTO.—The Toronto Local Board of Health has recommended recently the purchase for $30,000 (£6000) of a site overlooking the ravine and comprising 10 acres for the erection of an isolation hospital.

Dr. Charles F. Harford has been transferred from the post of physician to the Church Missionary Society to that of the secretary of the medical committee, with supervision of the medical missions of the society, comprising 48 stations, in which 91 medical men and women and 59 nurses are working. The statistics for the last completed year were: beds, 3388; in-patients, 31,871; out-patients, 1,136,518. Dr. Harford still continues as Principal of Livingstone College, as he did when holding his former post.

NEWCASTLE-ON-TYNE CLINICAL SOCIETY.—The first ordinary meeting of this society was held on Oct. 5th. The retiring President, Dr. E. N. Burnett, occupied the chair, and there were present 56 members. After some business proceedings, including the reports of the honorary secretaries and treasurer, Dr. Burnett vacated the chair and invited the President-elect, Dr. Andrew Smith, to occupy it. Dr. Smith then delivered the presidential address, his subject being "The Country Doctor," which was received with great enthusiasm by the large meeting.

THE VENTILATION OF SMALL DWELLINGS.—Lord Mount Edgcumbe, who resides at Mount Edgcumbe, near Plymouth, has, through the local press, made an offer to give £50 for the best paper on the subject of ventilation for small dwellings. Lord Mount Edgcumbe "states that if some persons with practical knowledge of the subject, such as medical men, clergymen, architects, &c., would care to express an interest in the matter, a meeting might perhaps be arranged and a committee appointed to propose a mode of competition." Lord Mount Edgcumbe considers "that the subject of ventilation of small dwellings is worth more consideration than it has hitherto received on the part of those who are interested in public health."

LITERARY INTELLIGENCE.—Vol. V. of the new edition of "Allen's Commercial Organic Analysis" is announced for publication by Messrs. J. & A. Churchill. This volume has been rewritten under the editorship of W. A. Davis, B Sc., and S. S. Sadtler, S.B. The subjects and authors are as follows: Tannins, Leather, Dyes, and Colouring Matters, by W. P. Dreaper; Diphenylmethane and Triphenylmethane Colouring Matters, &c., by J. T. Hewitt; Colouring Matters of Natural Origin, by W. M. Gardner; Analysis of Colouring Matters, by W. P. Dreaper and E. Feilmann; Inks, Carbon Papers, Typewriter Ribbons, &c., by P. H. Walker; Colouring Matters in Food, by A. F. Seeker.

MEDICAL OFFICERS OF HEALTH SOCIETY.—Dr. A. G. R. Cameron, President of the Southern Branch of the Society of Medical Officers of Health, in his address at the annual meeting of the branch at Chichester on Oct. 6th, dealt with the subject of the unequal manner in which the Public Health Acts and regulations are enforced in rural and small urban districts. Dr. Cameron quoted instances, and advocated annual Government grants to sanitary authorities as an incentive to the carrying out of sanitary measures, as was already done in the case of public elementary schools. Dr. Cameron strongly recommended that the powers of executive officers should be strengthened, and that adequate administrative facilities should be afforded for the carrying out of their work and the coördination of the duties of medical officers of health and clerks of district councils.

BOOKS, ETC., RECEIVED.

ALLEN, GEORGE, AND CO., LIMITED, Ruskin House, 44 & 45, Rathbone-place, London, W.

Births, Marriages, and Deaths.

BIRTHS.

BARENDT.—On Oct. 4th, at Rodney-street, Liverpool, W., the wife of Frank H. Barendt, M.D. Lond., F.R.C.S. Eng., of a son.

SMALLEY.—On Oct. 5th, at Suva, Fiji Islands, the wife of James Thornton Smalley, M.R.C.S. Eng., L.R.C.P. Lond., of a daughter.

MARRIAGES.

EDMUNDS—STRATFORD.—On Oct. 4th, at Locking Church, Somerset, by the Rev. F. Jackson, M.A., Arthur Edmunds, M.S. Lond., F.R.C.S. Eng., youngest son of the late Joseph Edmunds of London, to Maud Dampier, youngest daughter of the late Martin Stratford of Gloucester.

DEATHS.

BELL.—On Oct. 4th, at Mauricewood, Milton Bridge, Midlothian, Joseph Bell, M.D., F.R.C.S.E., J.P., D.L.

CAMPBELL.—On Oct. 8th, at Palace Gardens-terrace, Kensington, Brigade-Surgeon Alexander Dugald Campbell, late H.M.'s Bengal Medical Service.

GÜNTHER.—On Oct. 6th, at Hampton Wick, Theodore Günther, M.D., aged 77 years.

JACKSON.—On Oct. 7th, at Manchester-square, W., John Hughlings Jackson, M.D., LL.D., D.Sc., Hon. M.D. Bologna, F.R.S., Consulting Physician to the London Hospital and to the Hospital for Epilepsy and Paralysis, aged 76 years.

LITTLE.—On Oct. 4th, Louis Stromeyer Little, B.A. Lond., F.R.C.S. Eng., M.D. Kiel, of The Roughets, Blechingley, and late of Shanghai, China, in his 71st year.

MILLER.—On Oct. 9th, at Overfield, Bickley, Kent, John Nicholas Miller, M.D. Lond., aged 74 years.

THOM.—George Thom, M.R.C.S., of 1, Clarendon-terrace, Devonport, died suddenly on Oct. 8th.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

QUACKERY IN THE EAST.

AN Indian correspondent has sent us some pages from a price-list issued by a native saddler in Cawnpore. Our correspondent remarks that it is a unique example of the extremes to which uncontrolled quackery can run, and that it shows the type of remedy for which there is a demand in India. Incidentally, he adds, the advertisements have a humorous aspect, and with this we find it hard to disagree. The catalogue of the Medicine Department of Messrs. Mohamed Shafi and Co. has for its text the admirable sentiment, "Health is the Life of the Body," and it fills seven quarto pages. The 80 or so preparations (which are all compounded under the eye of "a very able doctor," Mohamed Sayed) cost from 1 to 5 rupees each, and they are guaranteed to be infallible remedies for almost all the ailments and disabilities to which mankind is heir. An "Oil for the remedy of the errors of youth" is especially recommended, and a Tonic for Weakness which "proves to be a stuff for old people." But there is something for everybody in Mohamed Shafi's price list, and no one need despair who has a rupee or two to invest. Barrenness, baldness, and bugs disappear like the mists of morning, and "foreign humours" can be driven from a "disorderly stomach." A charm for removing snakes and scorpions can be bought for the same price as a specific for small-pox marks which "removes the complexion." With reference to condensed milk at 12 annas the tin, "the public are informed not to be deceived by buying cheap and superious milk." Prophylactic bangles and lockets cost only 2 or 3 rupees each and effectually ward off "cholera weakness, cold, thinness, fever cough, inflammation of the eyes, erysipelas, indigestion, small-pox, impurity of blood, fits, and many other diseases to which children are subject." A plaster which has cured hopeless cases will "heal any old man and obstinate ulcer," while if Tooth Oil is used intelligently the user for the rest of his life "will have a set of unshaken teeth." Jawahar Mohra (or Tone Restorer) "makes a man patent," and Sukha cures "infants who pine away and ultimately die." Although "the inflammation of kidney is fatal," Mohamed Shafi has a remedy which never fails to cure it, and the price of a box is 2 rupees. Should you wish to give up opium, chandoo or spirituous liquors, he has a "life-saving thing which will relieve you radically" for 5 rupees the bottle. All through the catalogue there is an echo of the familiar clap-trap of Western quackery, and, though the reverse might be expected with a bait intended for ignorant and superstitious Orientals, the claims are not more impudent and the suggestions not more frankly obscene. The saddler of Cawnpore has not much to learn from the patent medicine vendors of the United States.

A REMINISCENCE OF MATTHEW WEBB.

To the Editor of THE LANCET.

SIR,—I read with great interest the recent comments and account of the Channel swim, for I knew Matthew Webb well, the first to accomplish that great feat. Matthew Webb before his last fatal effort came to consult me professionally in New York, where at that time I was practising medicine. He was then suffering from deafness produced by his arduous life, commonly known there as "sailor's deafness"; he had perforation of the tympanum. I examined him and had a special opinion also on his case, and as a result advised him on no account to attempt the desperate exploit, telling him that it appeared to be an absolutely impossible thing for any man, under any circumstances, to accomplish such a feat, while failure meant certain death. He was not to be dissuaded, however, but said, "I shall do it, sir, and you will be the first gentleman that I shall see when I return." So I said, "Good-bye, Webb," and he departed.

Matthew Webb before that had been an A.B. seaman before the mast on the R.M.S. *Russia* of the Cunard service, and performed there a wonderful deed. Two men were working on the after part of the saloon deck of the vessel; the ship was going from New York to Liverpool, with close-reefed topsails, at 17 knots an hour, Captain Theodore Cook, commander. At 4 o'clock in the afternoon the cry was raised "Man overboard." Webb's mate had been washed overboard and Webb followed him. The ship was put about, and for an hour and a half the man was not visible from the fore top-mast. Webb was picked up and came on board with the cap of the unfortunate man, the only souvenir of his lost mate. When asked why he did it, he said: "I thought I could save my mate, and I knew that the little captain would not leave me." His after-history is well known, as well as his fatal swim. His body was never found. Knowing Webb well as I did, I had many opportunities of observing his striking personality; he was the model of an English sailor—calm, self-possessed, and brave, and one to whom duty was everything.

I am, Sir, yours faithfully,

Bournemouth, Sept. 30th, 1911. R. A. CALDWELL.

BREATHING EXERCISES FOR CHILDREN.

To the Editor of THE LANCET.

SIR,—Can any of your readers tell me of a small book, about 1*s.* to 2*s.* 6*d.*, suitable for nurses giving instructions in the above?

I am, Sir, yours faithfully,

Oct. 3rd, 1911. BERK.

Anti-humbug.—The two symptoms arise from so many conditions that there can be no specific cure for them. Where they arise from special causes the dermatologist should be consulted; he will be able to advise if any general line of treatment would be useful in addition to, or instead of, local measures, and to indicate where advice should be sought.

"*Rustic*," a medical man, would be glad of advice from his medical brethren as to the treatment of a boy aged 5 years who has recently begun to stammer. His health is excellent, he does no lessons, and leads an out-door life. His father stammered as a boy and his uncle and great-uncle stammer.

J. D. L. writes:—"Can any reader of THE LANCET tell me where I can hire or buy a set of lantern slides suitable for a course of popular lectures on hygiene, especially showing bacteria, &c., and where I can procure a set of suitable diagrams?"

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

A DIARY OF CONGRESSES.

THE following Congresses, Conferences, and Exhibitions are announced for 1911:—

April–October.—Rome Exhibition (United Italy's Jubilee).
" 29th–Oct. 26th (Turin).—International Exhibition.
May 3rd–Oct. 31st (Glasgow).—Scottish Exhibition.
" 6th–Oct. 31st (Dresden).—International Hygiene Exhibition (British Section opens June 14th).
May 12th–Oct. 31st (London, Crystal Palace).—Festival of Empire Imperial Exhibition. (Profits to King Edward VII. Hospital Fund.)
May 18th–October 31st (London, Shepherd's Bush).—Coronation Exhibition.
Sept. 19th–Oct. 31st (London).—Earl's Court Exhibition.

Dr. J. B. Cleland: An Organism Isolated from an Abscess in the Neck of a Bullock.
Dr. P. Cole: The Muci-carmine Staining Method (Demonstration).

THURSDAY.

DERMATOLOGICAL SECTION (Hon. Secretaries—J. H. Sequeira, Wilfred Fox), at 11, Chandos-street, W.: at 5 P.M.

Demonstration of Cases.

FRIDAY.

OTOLOGICAL SECTION (Hon. Secretaries—Sydney Scott, A. Logan Turner), at 11, Chandos-street, W.: at 5 P.M.

Presidential Address:
Dr. W. Milligan.

Cases will be shown by:
Mr. Yearsley, Mr. Lake, Mr. Nixon Biggs, Mr. Arthur Cheatle, Dr. Milligan, Dr. Dundas Grant, Mr. West, and others.

ELECTRO-THERAPEUTICAL SECTION (Hon. Secretaries—G. Harrison Orton, Cecil R. C. Lyster): at 8.30 P.M.

Presidential Address:
Mr. Archibald D. Reid.

MEDICO-LEGAL SOCIETY, 11, Chandos-street, Cavendish-square, W.

TUESDAY.—8.30 P.M., Mr. R. Burrows: Note on a Recent Murder Trial.—Mr. W. Asten: Traumatic Neurasthenia.

ROYAL MICROSCOPICAL SOCIETY, 20, Hanover-square, W.

WEDNESDAY.—8 P.M., Mr. T. W. Butcher: Structural Details of Coscinodiscus Asteromphalus.—Mr. A. Flatters: Abstract of Paper on the Wheat Plant.—Rev. H. Friend: New British Enchytraeids.—Mr. W. Bagshaw: Instantaneous Exposure in Photomicrography.

OPHTHALMOLOGICAL SOCIETY, 11, Chandos-street, Cavendish-square, W.

THURSDAY.—8 P.M., Card Specimen will be shown by Mr. G. Coats. 8.30 P.M.: The President: Introductory Address. Mr. E. Nettleship: A New Case of Hereditary Night-blindness.—Mr. J. S. Manson: A Case of Hereditary Cataract (communicated by Mr. Nettleship).

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

ROYAL COLLEGE OF PHYSICIANS OF LONDON, Pall Mall East.

WEDNESDAY.—4 P.M., Dr. C. T. Williams: Harveian Oration.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC, 22, Chenies-street, W.C.

MONDAY.—4 P.M., Mr. G. Pernet: Clinique (Skin). 5.15 P.M., Lecture:—Mr. H. B. Robinson: Internal Strangulation.

TUESDAY.—4 P.M., Dr. R. H. Miller: Clinique (Medical). 5.15 P.M., Lecture:—Dr. J. Donelan: Some Points in the Diagnosis and Treatment of Intra-nasal Suppuration.

WEDNESDAY.—4 P.M., Mr. A. H. Tubby: Clinique (Surgical). 5.15 P.M., Lecture:—Dr. F. W. Price: The Early Diagnosis of Pulmonary Tuberculosis.

THURSDAY.—4 P.M., Mr. V. W. Low: Clinique (Surgical). 5.15 P.M., Lecture:—Dr. J. Morrison: Induction of Premature Labour.

FRIDAY.—4 P.M., Mr. E. B. Waggett: Clinique (Ear, Nose, and Throat).

POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.

MONDAY.—10 A.M., Surgical Registrar: Demonstration of Cases in Wards. Dr. Simson: Diseases of Women. 12 noon, Dr. Bernstein: Pathological Demonstration. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. 2.30 P.M., Mr. Dunn: Diseases of the Eye. 5 P.M., Lecture:—Dr. R. Jones: The Medical Treatment of Insanity.

TUESDAY.—10 A.M., Dr. Robinson: Gynæcological Operations. 11.30 A.M., Mr. Etherington-Smith: Demonstration of Minor Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. 2.30 P.M., Dr. Abraham: Diseases of the Skin. 5 P.M., Lecture:—Dr. Berstein: Blood Examination—Morphology.

WEDNESDAY.—10 A.M., Dr. Simson: Gynæcological Demonstration. Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. Mr. B. Harman: Diseases of the Eye. 2.30 P.M., Dr. Simson: Diseases of Women. 5 P.M., Dr. Beddard: Practical Medicine. (Lecture I.).

THURSDAY.—10 A.M., Surgical Registrar: Demonstration of Cases in Wards. 12.15 P.M., Lecture:—Dr. G. Stewart: Practical Medicine. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. 2.30 P.M., Mr. Dunn: Diseases of the Eye. 5 P.M., Lecture:—Dr. Morton: Radio-Therapeutics.

FRIDAY.—10 A.M., Dr. Robinson: Gynæcological Operations. 12.15 P.M., Lecture:—Dr. Pritchard: Practical Medicine. 2 P.M., Medical and Surgical Clinics. X Rays. Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. 2.30 P.M., Dr. Abraham: Diseases of the Skin. 5 P.M., Clinical Lecture:—Dr. D. Robinson: Gynæcological or Obstetrical Subjects.

SATURDAY.—10 A.M., Medical Registrar: Demonstration of Cases in Wards. Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. Mr. Bishop Harman: Diseases of the Eye. 2 P.M., Medical and Surgical Clinics. X Rays. Operations.

LONDON SCHOOL OF CLINICAL MEDICINE, Dreadnought Hospital, Greenwich.

MONDAY.—2 P.M., Operations. 2.15 P.M., Mr. Turner: Surgery. 3.15 P.M., Sir Dyce Duckworth: Medicine. 4.30 P.M., Mr. R. Lake: Ear and Throat. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Ear and Throat.

TUESDAY.—2 P.M., Operations. 3.15 P.M., Dr. R. Wells: Medicine. 2.15 P.M., Mr. R. Carling: Surgery. 4.15 P.M., Sir M. Morris: Diseases of the Skin. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Skin.

WEDNESDAY.—2 P.M., Operations. 2.15 P.M., Dr. F. Taylor: Medicine. 3.30 P.M., Mr. Cargill: Ophthalmology. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 11 A.M., Eye. 3.30 P.M., Special Lecture:—Mr. Cargill: Hints on the Routine Examination of the Eyes.

THURSDAY.—2 P.M., Operations. 2.15 P.M., Dr. G. Rankin: Medicine. 3.15 P.M., Sir W. Bennett: Surgery. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Ear and Throat. 4.30 P.M., Special Lecture:—Mr. Pendlebury; Cæcostomy.

FRIDAY.—2 P.M., Operations. 2.15 P.M., Sir J. Rose Bradford: Medicine. 3.15 P.M., Mr. McGavin: Surgery. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Skin.

SATURDAY.—10 A.M., Radiography. 11 A.M., Dr. A. Davies: Pathological Demonstration. 2 P.M., Operations. Out-patient Demonstration:—10 A.M., Surgical and Medical. 11 A.M., Eye.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.

MONDAY.—Clinics:—10 A.M., Surgical Out-patient (Mr. E. Gillespie). 2.30 P.M., Medical Out-patient (Dr. T. R. Whipham); Nose, Throat, and Ear (Mr. H. W. Carson).

TUESDAY.—Clinic:—10 A.M., Medical Out-patient (Dr. A. G. Auld). 2.30 P.M., Operations. Clinics:—Surgical (Mr. Howell Evans); Gynæcological (Dr. A. E. Giles). 3.30 P.M., Medical In-patient (Dr. A. J. Whiting).

WEDNESDAY.—Clinics:—2.30 P.M., Medical Out-patient (Dr. T. R. Whipham); Skin (Dr. G. N. Meachen); Eye (Mr. R. P. Brooks). 3 P.M., X Rays (Dr. A. H. Pirie).

THURSDAY.—2.30 P.M., Gynæcological Operations (Dr. A. E. Giles). Clinics:—Medical Out-patient (Dr. A. J. Whiting); Surgical (Mr. Carson). 3 P.M., Medical In-patient (Dr. G. P. Chappel). 4.30 P.M., Lecture: Mr. H. W. Carson: The Late Complications of Peritonitis.

FRIDAY.—2.30 P.M., Operations. Clinics:—Medical Out-patient (Dr. A. G. Auld); Surgical (Mr. E. Gillespie); Eye (Mr. R. P. Brooks). 3 P.M., Medical In-patient (Dr. R. M. Leslie).

CENTRAL LONDON THROAT AND EAR HOSPITAL, Gray's Inn-road, W.C.

TUESDAY.—3.45 P.M., Mr. J. G. French: Pharynx and Naso-pharynx.
FRIDAY.—3.45 P.M., Dr. Abercrombie: Pharynx and Naso-pharynx.

ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN, 49, Leicester-square, W.C.

THURSDAY.—6 P.M., Chesterfield Lecture:—Dr. M. Dockrell: Eczema (its Varieties, Symptoms, and Causes).

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, Queen-square, Bloomsbury, W.C.

TUESDAY.—3.30 P.M., Clinical Lecture:—Dr. H. Tooth.
FRIDAY.—3.30 P.M., Clinical Lecture:—Mr. L. Paton: Oculo-motor Paralysis.

ANCOATS HOSPITAL, Manchester.

THURSDAY.—4.15 P.M., Dr. C. H. Melland: The Treatment of Heart Disease. (Post-Graduate Clinic.)

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic (2 P.M.), Hospital operations are performed daily.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will insure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free from THE LANCET Offices, have been reduced, and are now as follows:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 1 0	One Year	£1 5 0
Six Months	0 12 6	Six Months	0 14 0
Three Months	0 6 6	Three Months	0 7 0

(The rate for the United Kingdom will apply also to Medical Subordinates in India whose rates of pay, including allowances, is less than Rs.50 per month.)

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied.

SOLE AGENTS FOR AMERICA—Messrs. WILLIAM WOOD AND CO., 51, Fifth Avenue, New York, U.S.A.

METEOROLOGICAL READINGS.

Harveian Oration

ON

OLD AND NEW VIEWS ON THE TREATMENT OF CONSUMPTION.

Delivered before the Royal College of Physicians of London on Oct. 18th, 1911,

BY C. THEODORE WILLIAMS, M.V.O., M.D. OXON., F.R.C.P. LOND.,

CONSULTING PHYSICIAN TO KING EDWARD VII. SANATORIUM AND TO THE BROMPTON HOSPITAL.

MR. PRESIDENT AND GENTLEMEN,—Two hundred and fifty-five years have elapsed since William Harvey instituted this festival, directing that a Fellow of the College shall be appointed to make an oration in commemoration of all the benefactors of the said College, "with an exhortation to all Fellows and Members of the said College to search and study out the secrets of Nature by way of experiment; and also for the honour of the profession to continue in mutual love and affection among themselves, without which neither the dignity of the College can be preserved nor yet particular men receive that benefit by their admission into the College which they might expect, ever remembering that 'Concordiâ res parvæ crescunt, discordiâ magnæ dilabuntur.'" Such are the words of Harvey, and such are the precepts which this College has, to the best of its ability, endeavoured to obey for centuries.

We have had many and distinguished benefactors, and these have been duly celebrated in the various orations, but as Harvey, by his immortal discovery, has outshone all the other luminaries, and as he was the founder of the institution, the numerous orations have been, for the most part, dedicated to the celebration and exposition of his magnificent labours and achievements. When we bear in mind the numbers and the distinction of the past orators and the many periods of history in which they lived it will be obvious to all here to-day that it is impossible for me to say anything regarding the discovery of the circulation which has not been already said; for again and again the Harveian orators have eloquently set forth its originality and importance, the steps by which it was attained, and the work of previous labourers in the same field.

When you, Sir, appointed me Harveian orator and conferred on me the highest honour you have to bestow in this College, you accompanied the command with a desire that, after due and proper reference to the work of our great benefactor, I should dwell more particularly on the subject to which I have devoted a large portion of my life—viz., tuberculosis; and I will endeavour to carry out your wishes to the best of my ability.

First, to comply with my orders, let us briefly contemplate the state of knowledge concerning the circulation of the blood before Harvey commenced his investigations.

KNOWLEDGE OF THE CIRCULATION IN THE EARLY TIMES.

Aristotle had taught that in man and the higher animals the blood was elaborated from the food in the liver, whence it was carried to the heart and distributed through the veins over the body. His successors of the Alexandrine School of Medicine, Erasistratus and Herophilus, further amplified his system, and explained that while the veins carried blood from the heart to the members, the arteries carried a subtle kind of air or spirit. According to Dr. Pye-Smith's admirable epitome of the subject, only two changes had been made, for the practical physician, in this theory of the circulation between the Christian era and the sixteenth century.

Galen had discovered that the arteries were not, as their name implies, merely air tubes, but that they contained blood as well as vital air or spirit, and it had been gradually ascertained that the nerves (*νεῦρα*) which arose from the brain and conveyed animal spirits to the body were different from the tendons and sinews (*νεῦρα*) which attach themselves to bones.

The state of knowledge may be summarised as follows:—

1. At the time of Linacre (1524) physicians knew that the blood was not stagnant in the body, for this had been apparent even to the ancient augurs when they inspected the entrails of a victim and, as Dr. Pye-Smith remarked, to every village barber who "breathed" a vein; but no one had a conception of a continuous stream returning to its source—i.e., of a circulation in the true sense of the word—either in the system or lungs, for they were only cognisant of some slow and irregular movement of the blood.

2. Physicians, before Harvey, supposed that one kind of blood flowed from the liver to the right ventricle of the heart and thence to the lungs and the general system by the veins, and that another kind flowed from the left ventricle to the lungs and general system by the arteries.

3. They supposed that the heart's septum was pervious and allowed blood to pass directly from the right to the left side.

4. They had no conception of the functions of the heart as the motor power of the movement of the blood. They doubted if its substance were muscular; they supposed its pulsations to be due to the expansion of the spirits it contained. They believed the only dynamic effect which it had on the blood to be that of sucking it in during its active diastole; they supposed the chief use of its constant movements to be the due admixture of blood and spirits.

When we come to the sixteenth century we find that Jacobus Sylvius discovered the valves of the veins, more fully described later by Fabricius, and that Vesalius ascertained that the septum between the right and left ventricle was complete in the adult. Servetus, whose works, having been burnt, were probably never seen by Harvey, had certain theories of the existence of the lesser circulation, which were confirmed later by Realdus Columbus, for the latter taught that blood and spirits pass from the right to the left ventricle, not through the septum, but through the lungs.

DISCOVERY OF THE MECHANISM OF THE CIRCULATION BY HARVEY.

Such was the state of knowledge when Harvey commenced his long and painstaking series of researches and observations, and he prefaces his account of them with the following words, with which all students of cardiac pathology have probably some time or other felt sympathy:—

> When I first gave my mind to vivisections as a means of discovering the motions and uses of the heart, and sought to discover these from actual inspection and not from the writings of others, I found the task so truly arduous, so full of difficulties, that I was almost tempted to think with Frascatorius that the motion of the heart was only to be comprehended by God. For I could neither rightly perceive at first when the diastole took place, nor when and where dilatation and contraction occurred by reason of the rapidity of the motion, which in many animals is accomplished in the twinkling of an eye, coming and going like a flash of lightning, so that the systole presented itself to me now from this point, now from that; the diastole the same; and then everything was reversed, the motions occurring as it seemed, variously and confusedly together.
>
> At length by using greater and daily diligence, having frequent recourse to vivisections and employing numerous observations, I thought I had attained to the truth that I should extricate myself and escape from this labyrinth and that I had discovered what I had so much desired, both the motion and the use of the heart and arteries. Since which time I have not hesitated to expose my views upon these subjects, not only in private to my friends, but also in public in my anatomical lectures, after the manner of the Academy of old.

Then after many years of demonstrations, in his Lumleian lectures, he published his well-known "Exercitatio de Motu Cordis et Sanguinis," a work of 67 pages, marvellous for its conciseness, in which he proves for all time—

> (1) That it is the contraction, not the dilatation of the heart which coincides with the pulse, and that the ventricles, as true muscular sacs, squeeze the blood which they contain into the aorta and pulmonary artery; (2) that the pulse is not produced by the arteries enlarging and so filling, but by the arteries being filled with blood and so enlarging; (3) that there are no pores in the septum of the heart, so that the whole blood in the right ventricle is sent to the lungs and round by the pulmonary veins to the left ventricle, and also that the whole blood in the left ventricle is again sent into the arteries round by the smaller veins into the venæ cavæ, and by them to the right ventricle again, thus making a complete double "circulation"; (4) that the blood in the arteries and that in the veins is the same blood; (5) that the action of the right and left sides of the heart, auricles, ventricles, and valves is the same, the mechanism in both being for reception and propulsion of liquid and not of air, since the blood on the left side, though mixed with air, is still blood; (6) that the blood sent through the arteries to the tissues is not all used, but that most of it runs through into the veins; (7) that there is no to-and-fro undulation in the veins, but a constant stream from the distant parts towards the heart; (8) that the dynamical starting-point of the blood is the heart and not the liver.

One part of the circulation Harvey did not discover—viz., the capillaries. He had demonstrated the communication between arteries and veins in three situations—the choroid plexus, the spermatic vessels, and the umbilical vessels—but having no microscope he had to leave the discovery of the

capillaries to others, and four years after his death Malpighi, by the use of the newly invented microscope, showed in the lungs of a frog how the blood passes from one set of vessels to the other. Thus was the wondrous cycle made complete and the circulation of the blood, both lesser and greater, manifested to mankind.

Though Harvey's discovery was attacked and subjected to the severest criticism he lived to see it firmly established in the annals of medicine and to witness the conversion of the greater number of his opponents, but this is not to be wondered at when we consider the mass of evidence from observations and experiments on all classes of creation on which the discovery rests, the splendid and convincing logic of Harvey's arguments, and the modest and unpretending simplicity with which the discovery was put forward.

SOME RESULTS OF THE DISCOVERY.

With your permission, Mr. President, let us now picture Harvey contemplating some of the scientific truths which have been revealed as the result of the great discovery. Harvey himself sanctions such speculation, for in his second disquisition to John Riolanus, Junior, he remarks "how speedily is pain relieved or removed by the detraction of blood, the application of cupping glasses, or the compression of the artery which leads to the part. It sometimes vanishes as if by magic." He then refers us to his medical observations where his views will be found at length exposed and explained, observations which were, alas, destroyed when his house was sacked by Cromwell's soldiers. He could then see local abstraction of blood and the use of the tourniquet set forth, but when our great master glanced over ages to come he would soon have come upon a harvest of new facts, physiological, clinical, pathological, and therapeutical, which might all be traced to his grand discovery! What would he have thought of the phenomena of embolism of the arteries, which is the key to so many conditions of the brain and other organs, or again, of thrombosis and the inflammatory conditions of the walls of the veins and their effects on the circulation?

How delighted Harvey would have been with the discovery of mediate auscultation by Laennec and the consequent provision of a ready method for ascertaining and of estimating the sounds and murmurs of the heart! With what interest would he not have followed the experiments carried on in this city by Hope, C. J. B. Williams, and Glendinning, which, to use the terms of the report, concluded "that the first or systolic sound is essentially caused by the sudden and forcible tightening of the muscular fibres of the ventricles when they contract, and that the second sound, which accompanies the diastole of the ventricle, depends solely on the reaction of the arterial columns of blood on the semilunar valves of the arterial orifices."

Harvey would also have welcomed the graphic method introduced by Ludwig and his disciples and applied by Volkmann, Chauveau, and Marey to the registration of the pulse in the form of the cardiograph, sphygmograph, and to the measurement of the blood pressure, and probably, if he could have availed himself of such help, he would further have enriched our field by fresh discoveries of no small importance.

When we come to the practical uses of the knowledge of the circulation, what would Harvey not have thought of transfusion of blood, of the administration of anæsthetics, of hypodermic injections, &c., all which depend on this knowledge. Transfusion of blood[1] is only used in extreme and exceptional cases, and then is a procedure fraught with some danger, but the administration of anæsthetics is one of the greatest boons that have ever been granted to human and animal suffering, and has, in Sir James Paget's words, more than any other discovery, added to the sum of human happiness.

> Past all counting is the sum of happiness enjoyed by the millions who for the last years have escaped the pains which were inevitable in surgical operations, pains made more terrible by apprehension, more keen by close attention, sometimes awful in a swift agony, sometimes prolonged beyond the most patient endurance and then renewed in memory or in terrible dreams.

What a delight to Harvey to feel that his discovery had been the foundation of such blessed advances in medicine and surgery!

Intravenous injections of medicines, according to Sir Lauder Brunton, were first practised by Sir Christopher Wren, the famous architect of St. Paul's, who was a medical graduate of Oxford and a very successful experimenter, and, according to Bishop Spratt,[2] "by his injections divers creatures were immediately purged, vomited, intoxicated, killed, or revived according to the quality of the liquor injected." Intravenous injection was certainly an outcome of Harvey's discovery, and the process has been perfected by successive experimenters, and largely employed. But perhaps more important and certainly more useful has been hypodermic injection, the first instrument for which was devised by Dr. Alexander Wood, and which is so simple a procedure that it is employed not only by medical men and nurses, but too frequently by patients themselves and often to their disadvantage. Not only are drugs of various kinds administered in this way, but the different vaccines, tuberculin, and the like, and this method to which Harvey's discovery opened the door presents a vista of possibilities of which the master could hardly have dreamed.

TUBERCULOSIS.

I will now proceed according to your wishes, Mr. President, to give some account of the knowledge of tuberculosis which existed at the time of Harvey, and, with your permission, will trace the steps by which that knowledge has been extended and increased in the centuries which separate us from Harvey. The tale is not altogether a pleasant one, but one moral, at any rate, can be drawn—viz., that no satisfactory progress can be made in the investigation of disease unless the Harveian system of searching out the secrets of nature by way of experiment is employed.

SCROFULA.

When I take up my parable concerning tuberculosis of various kinds a smile of contentment would, I think, spread over Harvey's philosophic countenance as he realised the successive advances in knowledge; for in his time the principal treatment for "les scrofules dites écrouelles"—i.e., cases of scrofula or king's evil—was the royal touch, which was held to be of special virtue when the sovereign had just been consecrated. One of the first acts of Henry IV. of France when he entered his new capital, Paris, was to administer his royal touch to 600 scrofulous patients who flocked to him. According to Laurens, who published a book in 1609 on the subject, and also according to Professor Landouzy, to whom I am much indebted for information, the king's evil was regarded as a disease both hereditary and contagious, for the suppurating sores were held capable of contaminating healthy people, and their healing was difficult. In 1645 a pious lady founded in the Isle of France a hospital dedicated to St. Marcoul reserved for contagious scrofulous cases (*reservé au mal des écrouelles qui se communique*). The practice of the royal touch began in France with Clovis and in England with Edward the Confessor, and continued to a late period, in France till Charles X. (1824). In Spain the practice was in great vogue, and the Spaniards who were scrofulous would crowd to any city visited by their king for "*le Roy les touchant, Dieu les guérit.*" According to Dr. Pettigrew,[3] in no reign in the history of England did the practice prevail to such an extent as it did in that of Charles II., and it is not a little remarkable that more people died from scrofula, according to the bills of mortality, during this period than in any other. It was even recommended by the faculty, for at the instigation of Sir John Floyer, a physician of eminence, Samuel Johnson was "twice touched by Queen Anne," and as Boswell remarked "evidently without success." Both William III. and George I. declined to touch for king's evil, the latter referring the child of an English gentleman to the Pretender as possessing the hereditary power of the Stuarts. The English gentleman took his advice. His son was touched and recovered, and the father was converted to the Stuart cause.[4]

I will say no more on the king's evil, as it has been the subject of the Fitz Patrick lectures at the College this year and has been ably and exhaustively treated by Dr. Raymond Crawfurd, whose book I have read with much interest.

[1] Transfusion of normal saline solution is practically free from danger, and has proved of the greatest value in saving life in cases of profuse hæmorrhage.

[4] Chambers's History of the Rebellion.

SOME EARLY WRITERS ON TUBERCULOSIS.

Harvey's writings do not contain many references to tuberculosis, though it is possible the lost "Medical Observations" treated of the subject, but I have taken the pains of going carefully through that remarkable document the "Prælectiones Anatomiæ" published by the College, which owing to the deciphering skill of Mr. Scott of the British Museum and the liberality of the College, supplies us with Harvey's Latin notes of his famous lectures, interspersed with sundry English expressive annotations. These contain much that is remarkable and instructive, but I failed to find any reference to consumption or other forms of tuberculosis. The "prælectiones" contain a good description of the anatomy of the lungs and of the process of respiration—so that, although we are acquainted with Harvey's views on many diseases, we do not know what doctrines he held on tuberculosis.

The first writer on this and other kindred subjects after Harvey's period was Dr. Christopher Bennett (Benedictus), a Fellow of this College, who published (in 1656) a little book in Latin entitled, "Tabidorum Theatrum sive Pthisios Atrophiæ et Hecticæ Xendochium," which gives an account of several forms of tabes or wasting, and devotes some 30 pages to phthisis, basing the diagnosis of that disease on the character of the sputum, its frequency, the fact of its being tinged with blood, the pains in the chest and the shortness of breath, and colliquative night sweats. He dwells on the weak, small, and frequent pulse, on the falling off of hair and the curving of the nails, and above all on the so-called "Hippocratic" countenance, "seu ipsa mortis imago, viz., facies lurida ac emortua, oculi subsidentes, nares acutæ, gena depressiores, collapsa tempora, corpusque totam strigosum sceleto finitimum." And to complete the horrors of the poor patient he adds as a characteristic, "omnium virtutum deficientia." The descriptions are picturesque, though often obscure, but the treatment proposed is bleeding, cough mixtures, and inhalations with hygienic and dietetic rules, some of the latter excellent, but there is no mention of fresh air, tonics, or exercise.

MORTON'S "PHTHISIOLOGIA."

The next work of importance on consumption in this country was published at the beginning of the eighteenth century, to wit, Richard Morton's "Phthisiologia, or Treatise of Consumption." It was originally published in Latin, afterwards translated into English, and ran through more than one edition, being evidently widely read and approved in the eighteenth century. The author treated of "Consumptions," not only of pulmonary consumption, but of many kinds of wasting disease, such as that arising from discharging abscesses, from diabetes, from loss of blood, and from excessive diarrhœa due to various causes, but he devoted his chief attention to pulmonary consumption, of the acute forms of which disease he certainly was an attentive observer, and had a considerable experience. Some of his distinctions are shrewd, such as those between the different kinds of cough prevailing in consumption and catarrh, and his remarks on the "prognosticks" are occasionally quite sound, as, for instance, "every Consumption, though it be cured, is apt to return, and he that has once been in a Consumption, unless he governs himself very regularly, falls back into the same Condition, even upon the least Occasion. For not only the Lungs, being already impaired by a former Attack from the Distemper, are the more apt to receive a new Impression, but there is likewise a greater Inclination and Dispesition to this Distemper from the Habit of the Body itself in these, than in other Persons. Yea, moreover, even after the most perfect Cure of a Consumption, there is reason to suspect that there are some crude Tubercles yet remaining, which at length may, by often meeting with an Occasion, be inflamed, and ripen into Apostemes, and so at last become Ulcers." What, however, can we say of his view of the etiology as thus set forth: "The cause of a Consumption of the Lungs in general is a vitiated Disposition of the Mass of Blood and of the Spirits in the Nerves, contracted gradually from several procatartick or predisposing Causes, in which the sharp or malignant Serum or Water of the Blood being separated by the soft and glandulous Substance of the Lungs, does stuff, inflame, and at length also exulcerate the Lungs themselves, which is the immediate Cause of this Distemper." Morton maintained that the dry cough of consumption was caused by tubercles in the lobes of the lungs which cause a tickling in the upper part of the windpipe, and stated that the same dry cough may be caused by "chalky stones" generated in the substance of the lungs. He also observed the same symptoms arising "from 3 Nails, that slipt by Chance" (as the person was laughing) "through the Windpipe down into the Lungs and Continued for a whole Year, the sick Person being in other respects very well"! Morton was a believer in the doctrine of phthisis ab hæmoptoe and does not seen to attribute the hæmoptysis to pre-existing tubercle. He also gives illustrations of phthisis by contagion for which, according to him, the prognosis is very unfavourable. Morton's pathology is very obscure and somewhat indefinite, but when we come to treatment of his cases, most of which are acute, he begins by bleeding "to prevent the Hectick and colliquative Heat or Catarrhous State of the Blood"; then, in order to carry off the load of the dispirited and diseased humours lodged in the habit of the body with convenient medicines, he recommends vomits, purges, diuretics, and sweating medicines. Finally, he administers woodlice, crab's eyes, the simple powder of crab's claws, red coral, and white amber in the form of powders or julep to "temper the Sharpness of the Blood." Poor consumptive, who might well exclaim with the Frenchman, "Laissez-moi mourir, mais ne me tuez pas!"

TREATMENT ADVOCATED BY SYDENHAM.

Sydenham,[5] the great physician of gout and fevers, dismisses phthisis in a few pages of his epistles. After a short and rather striking sketch of an advanced case he describes a less acute case, and considers that the treatment "which would suffice would be to abstain from meat and wine for a few days and to take a balsam of sulphur and anise with sugar in the form of tablets and then a cough mixture of oil of sweet almonds, syrup of maidenhair, and syrup of violets; this to be taken off a stick of liquorice. If the cough do not yield to these remedies, or if it have arisen from peripneumony or pleurisy, or is accompanied by fever, and this is generally the case, it is folly to trust to pectorals," the disease must be attacked by bleeding and purging; but if, "notwithstanding the latter method, the cough not only continue, but do shake the lungs as to have paved the way for phthisis," he recommends balsam of Peru; but Sydenham concludes "that of all the remedies for phthisis, long and continued journeys on horseback bear the bell, in respect of which must be noted, that if the patient be past the prime of life, more exercise of the sort in question must be taken than if he was a youth or boy. Bark is no surer a cure for ague than riding for phthisis."

LATER VIEWS.

In Mr. Ancell's[6] "Treatise on Tuberculosis" (1852) will be found a list of the different theories which have prevailed in bygone ages to explain the occurrence of tuberculous diseases. These are 54 in number and extend from the time of Hippocrates to that of Dr. Hughes Bennett, and they are as diverse as they are numerous. They show the large amount of attention bestowed on the subject in all ages and, in many cases, testify to the lively imagination of their authors. Most of these theories refer the cause of consumption to errors of digestion and errors in the formation of the lymph or chyle, or blood, or to defective respiration, or they assign an origin from inflammation, and as a rule mistake predisposing causes for the *vera causa*, which, though long suspected, was never actually discovered till Robert Koch appeared on the scene.

Laennec's benefit to this department of medicine was twofold. He successfully applied his great discovery to the clinical phenomena of pulmonary consumption and he also gave us the first good account of the morbid anatomy of tubercle, and insisted on what has been definitely proved since his time—viz., on the unity of the disease.

Matthew Baillie had in 1795, from observations on children, stated that tubercles were the essential cause of consumption and demonstrated their seat in the cellular tissue, distinguishing them from lymphatic glands, but the first to properly describe miliary tubercle was Bayle, the friend and contemporary of Laennec, and to this day the miliary tubercle found in the serous membranes is called in France "granulations de Bayle."

[5] Works of Sydenham, Sydenham Society, vol. ii.
[6] Ancell: A Treatise of Tuberculosis, p. 552.

Bayle, like Laennec, denied an inflammatory origin to miliary tubercle, and held it to be a product *sui generis*.

Broussais,[7] on the other hand, considered that tubercle had an inflammatory origin and that consumption depended on a chronic phlogosis, inflammation of the lungs, or catarrh, parenchymatous or bronchial, which, if prolonged by the cause that produces it, could impress the lymphatics of the lungs with a certain impulse, leading to the formation of tubercle or various deposits of tuberculous matter.

Anyone studying the writings of Andral and Bayle will soon come to the conclusion that they, with Laennec, had grasped the main truth of the nature of tubercle and its close association with consumption, proving that they were opposed to Broussais's opinion that tubercle originated from inflammation; but, unfortunately, whatever their pathology might be, they, in common with other pathologists of the time, founded all their *treatment* on an anti-inflammatory basis, and did not seem to have been able to contemplate any treatment for any serious disease without anti-inflammatory measures.

TREATMENT BY BLOOD-LETTING, &C.

Concerning blood-letting, Morton, Donar, Mead, Pringle, and Munro all recommended it for the early stages of consumption to subdue inflammation. Cheyne advised bleeding in hæmoptysis, where it certainly has great effect, in order to reduce the inflammatory state of the lungs produced by the irritation of tubercle and to arrest the progress of the disease. Even Sir James Clark, who was a very cautious physician, counsels bleeding under certain restrictions, as the following extract will show. He was of opinion[8]—

> That keeping before us the condition of our patient, the nature of his constitution, and the pathological condition of his lungs, and considering the utmost benefit which we can generally expect to derive from the practice is the removal, or the diminution, of congestion or inflammation, complicated with, and often dependent on, the presence of tubercles, keeping all these circumstances in view, blood may be abstracted with advantage at any stage of consumption, when the symptoms require it. After pulmonary congestion has been diminished by general bleeding, the abstraction of blood by cupping or leeches, where further depletion is necessary, has a very beneficial effect.

Most of the above authorities advised bleeding on the ground of reducing inflammatory conditions of the lungs, but some of the French physicians entertained other views of its possibilities. Laennec's opinions on the subject are highly interesting, and are evidently more shrewd than those of his contemporaries. He says:—

> The most rational indications for the treatment of phthisis are, first, to prevent the secondary eruption of tubercles, as in this case, if the primary tubercular masses were not extremely large or numerous, which they very seldom are, a cure would necessarily take place after they, the masses, are softened and evacuated; secondly, to promote the softening and evacuation or absorption of the existing crop of tubercles.

Laennec remarks that bleedings and derivatives have been used to prevent the development of tubercle, the greater number of physicians, however, not considering these a means of curing or even of preventing phthisis, but only calculated to allay the inflammatory affections with which it is complicated, but he adds that Broussais maintained that by bleeding he stopped the inflammatory conditions and rendered the occurrence of phthisis rare. Laennec himself held that bleeding could neither prevent the formation of tubercles nor cure them when formed. He says: "It ought never to be employed in the treatment of consumption except to remove inflammation or active determinations of blood, with which the disease may be complicated; beyond this its operation can only tend to a useless loss of strength." Laennec doubted if any one of the remedies reported to promote the softening of the tubercles really did so, but he thought the alkalis, including the carbonates of ammonia and soda, helped expectoration. He considered the best means of opposing the disease was by sea voyages or a residence on the sea coast in a mild climate, and he attempted to establish an artificial marine atmosphere in the Clinical Hospital in Paris, where he placed 12 consumptives in a ward the air of which was impregnated with fresh seaweed. He states that in all of these patients the disease remained stationary, and in some the emaciation and fever were sensibly lessened, and that nine left believing themselves to be cured.

Louis seems to have been sceptical about the treatment of phthisis generally, and only believed in palliative measures.

Another method of treatment which was much in vogue in the eighteenth and the beginning of the nineteenth century was by emetics, as we know by the evidence of Morton, Parr, Bryan, Reid, Marryatt, Young, and Sir James Clark himself, for the latter cites the cures of De Vettis at Naples by emetics of tartarised antimony, and states the benefit derived from this form of treatment is chiefly in threatened consumption, explaining that the repeated action of emetics may prevent the deposition, or at least the retention of tuberculous matter in the bronchial ramifications and air-cells, and thus prevent the localisation of the disease.

COMPARATIVE DURATION OF LIFE OF CONSUMPTIVES.

I have dealt rather fully with the treatment of consumption at the time of Laennec, Louis, James Clark, and others, because I wished to show that the short duration of life in their cases was clearly connected with the depressing measures then in vogue, and that the disease was not, as has been urged, of an utterly different type from that which prevails now, when the duration of life is much greater, and this can be proved by a comparison of some of the clinical descriptions. The best evidence on this point is that of Dr. C. J. B. Williams,[9] a favourite pupil of Laennec, who in 1871 gave the following facts:—

> In the first ten years of my practice (1830-40) the beneficial effect of treatment was limited to incipient cases, and especially to those who were able at an early stage to take long voyages, such as those to Australia and to India.

He adds:

> My general recollection of the histories of the developed disease at that time is that of distressing tragedies, in which no means used seemed to have any power to arrest the malady; and life was rarely prolonged beyond the limit of two years, assigned by Laennec and Louis as the average duration of the life of a consumptive.
>
> In the next period of ten years (from 1840 to 1860) a marked improvement took place in the results of treatment, apparently in connexion with the allowance of a more liberal diet, and the habitual use of mild alterative tonics, as they might be termed, particularly iodide of potassium with sarsaparilla, or other vegetable tonics. Several of the early cases recorded were treated in this way and with improved results in respect of the general health of the patients and diminution of cough and expectoration.
>
> It was in the latter half of this period that chemists began to produce cod-liver oil of sufficient purity and freshness to be fit for the human stomach; and I have no hesitation in stating my conviction that this agent has done more for the consumptive than all the other means put together.

TONIC TREATMENT OF PHTHISIS.

When I entered London practice in 1866 the tonic treatment of consumption had commenced, and according to the evidence of the first Brompton Report and of Dr. Hughes Bennett, Dr. C. J. B. Williams, and others, cod-liver oil was at the head of all consumption treatment and was in extensive use in hospital and private practice. The prevalent idea of treatment was, at that time, partly tonic, including a liberal dietary, and partly sedative to subdue symptoms. The climatic treatment was changing from the warm moist atmosphere of Madeira and the cold moist one of Pau to the dry warm and more bracing air of the Mediterranean shores. Sea voyages were still in vogue, and a few patients wintered in Egypt, while the English winter resorts were also in fashion. To live in an equable temperature, to sleep in a well-warmed room, and to winter in a more or less warm climate was the order of the day, and the era of unmitigated open air by day and night had hardly dawned. The Brompton Hospital experiment of sending patients to Madeira and my statistics drawn from my father's cases demonstrated that Madeira was undesirable for nearly all forms of consumption, as in spite of most of these patients being especially selected as suitable, they lost appetite and became languid, while the disease progressed rapidly and excavation proceeded.

That the introduction of cod-liver oil into the treatment of consumption exercised a wonderful effect on the outlook of the disease was well seen in the raised average of life among Dr. Pollock's out-patients at Brompton, in contrast to former estimates, and this seemed due to the oil alone, as these patients enjoyed no other special advantages in the way of food, exercise, climate, or sanitation, and my statistics also showed that the patients who persevered in the use of cod-liver oil at home did better than those who were sent to warm climates for the winter and did not persevere in its use.

In the Medico-Chirurgical Transactions of 1870 were

[7] Ancell, loc. cit., p. 553.

[9] Pulmonary Consumption, first edition, 1871.

published my statistics on the Duration of Life in 1000 Cases of Pulmonary Consumption among the Upper and Middle Classes. These patients were selected with the limitation of having been under treatment for one year and upwards, thus excluding most of the acute cases, which group was calculated to amount to 3 to 5 per cent. of the whole number. Of the 1000, 198 had died, and the average duration of their life since the onset of the disease was 7 years and 7 months; 802 were living, with a good expectation of further life in 72 per cent., and a present duration of 8 years 2·19 months since the first attack. This was the result arrived at before the era of sanatoriums, high altitude treatment, and vaccines. Now let us consider sanatorium treatment.

INTRODUCTION OF FRESH-AIR TREATMENT BY BODINGTON.

It is well known that the open-air and sanatorium treatment was originated in 1840 by Bodington of Sutton Coldfield and supported by Henry MacCormac, but it had been practically ignored in this country until a much later date and until after it had been adopted by Brehmer of Görbersdorf 15 years after Bodington's time, and later on by Dettweiler of Falkenstein.

It is curious to see in Bodington's original essay on the "Treatment and Cure of Pulmonary Consumption on Principles, Natural, Rational, and Successful," how completely its author grasps the principles of open-air treatment when he says "the only gas fit for the lungs is the pure atmosphere freely administered, its privation is the most constant and frequent cause of the progress of the disease. To live in and breathe freely the open-air without being deterred by wind or weather is the one and essential remedy in averting its progress." Bodington, as the late Dr. Bulstrode,[10] whose admirable Milroy lectures this College had the privilege of listening to some years ago, points out, had a clear insight into the requirements of the consumptive working man, for he says "provision should be made for the employment of the convalescent and cured patients who, if possible, should not return to their former occupation" (presumably an unhealthy one), "but should be employed as agricultural labourers or gardeners." Bodington furnished a suitable house for the reception of patients, engaged a medical superintendent to give them "almost hourly watchfulness," and made all necessary arrangements, but he was before his age. His views were ridiculed, and his sanatorium was soon emptied of patients and converted into a lunatic asylum! He lived long enough to see the establishment and spread of sanatoriums, at least in Germany, where it had been whispered that the need for fresh air was the sorest, and he prophesied that when he was dead and buried perhaps the medical profession would be more disposed to do him some justice than when he lived. Now, as a kind of posthumous justice to Bodington's memory, the City of Birmingham has erected the first municipal sanatorium for consumption in England a few miles from the pioneer's original institution, and Birmingham is now proud of her once neglected son.

SANATORIUMS IN GERMANY.

On German soil the sanatorium idea, after weathering opposition, slowly developed; the first example being Brehmer's at Görbersdorf in Silesia, in which methodical hill-climbing up graduated ascents was specially enjoined with the object of furthering the development of the heart—a small heart, according to Brehmer, being one of the greatest predisposing causes of phthisis. This sanatorium grew and prospered, and at present there are no less than four at Görbersdorf.

Dettweiler, a patient, and afterwards an assistant, of Brehmer, established at Falkenstein, in the Taunus mountains, a sanatorium, where for Brehmer's graduated ascents, he substituted the Liegehalle system, in which patients lie for several hours together in open shelters, and this system continues in general use in German sanatoriums.[11] Dettweiler fed his patients largely, proclaiming the kitchen to be the true pharmacy of the sanatorium, and he established a high ideal for the medical superintendent of such an institution, for he contends that it must be "all in all to him, his Religion, his Politics, his Despair, and his Delight." Dettweiler held for a long time a foremost position as the head of Falkenstein, which was a leading German sanatorium.

Dr. Walther of Nordrach strongly opposed the Liegehalle, which he nicknamed "quarrelling halls"—I presume in consequence of what he observed among the occupants, and he advocated instead a species of solitary confinement during the rest hours, but enjoined out-door walks in all weathers with a stuffing dietary, and his example has been followed in several of the British sanatoriums.

STATISTICS OF GERMAN SANATORIUMS.

Many of these institutions were established in North and South Germany, some for the poor from charitable funds, some for the well-to-do classes as private speculations, and some to supply the requirements of the German Insurance Society, the present result being a total of 137 with 16,548 beds for the working classes alone.

Whatever difference of opinion may exist as to the need for sanatoriums in this country, there is in Germany no doubt about their success, not only for the insured and for workers but for all classes of society. Dettweiler was, I believe, the first to start a sanatorium for the poor at Ruppertshain in the Taunus, and was followed by von Leyden, B. Fraenkel, Pannwitz, and others, who organised Belzig, while Bielefeldt and Gebhart stimulated the insurance companies to erect sanatoriums for their consumptive members, of which at present there exist 38 with 3169 beds for men and 1314 for women. The records of these sanatoriums, kept for a number of years and classified for the Imperial Health Office by Dr. Hamel and Dr. Engelmann, show decidedly favourable results both as regards general and local conditions, but as the German authorities in their statistics make the capacity for work the standard of improvement rather than tabulating cases as arrested or cured, comparison with most of the English statistics is difficult. According to these German tables 44 per cent. male and 51 per cent. female consumptives were capable of work four or five years after leaving the sanatorium. The statistics of the Hanseatic Towns sanatoriums, where the proportion of early cases was apparently greater, give 47 per cent. of male and 57 per cent. of female, and the Prussian and Hessian Railway employees sanatoriums yield still better results, for they show 59·6 per cent. of patients at work five years after leaving the sanatorium. Naturally the results of sanatorium treatment greatly depend on the amount of disease present when the patient is admitted and the length of the consumptive history.

The statistics of the German sanatoriums are instructive and important, as they are based on thousands of cases of the working classes, but as they treat of the subject only from the point of view of capability for work and wage-earning they are incomplete. When a comparison was once attempted between these and my statistics, which are fairly complete, I was asked what proportion of my cases returned to work, and I had to explain that they belonged to a different class and few did manual work as wage-earners, so that a comparison was not possible; but what is really wanted is a whole-life comparison to see how long these patients lived.

ACUTE CASES.

As Sir R. Douglas Powell and Dr. P. Horton-Smith Hartley emphasise in their recent work,[12] every effort should be made to persuade those suffering from phthisis to apply for treatment in the early stage, and it will be noted that the result of treatment depends largely on the proportion of early cases, though we must not accept the popular statement that all cases of phthisis, if taken early, are curable. The dictum may be said to be true if applied to the ordinary types of chronic phthisis, but we must except acute cases, which all pass through an early stage to a fatal issue.

Acute miliary tuberculosis for instance, sometimes primary, sometimes secondary, often presents the signs and symptoms of an early case of consumption, but speedily develops and destroys the patient in a few weeks. Acute pneumonic phthisis, or galloping consumption, is another hopeless form, when the patient's power of resistance is feeble and the dose of bacillar poison overwhelming. In the early stages the symptoms are often obscure and mask the true nature of the disease, which declares itself gradually; the lungs become consolidated with tubercle and rapidly break down into suppurating cavities, whole lungs being

[11] Sanatoria for Consumptives, by von Jaruntowsky. Translated by R. Clifford Beale.

[12] Diseases of Lungs, Powell and Hartley, fifth edition, 1911.

destroyed, and the victim perishing in a few weeks or months. It is true that in some of these cases the disintegrating process comes to a standstill and fibrosis sets in, the patient living on with a greatly diminished lung surface, though the disease is incapable of cure. Fortunately, acute tuberculosis and acute phthisis (galloping consumption) form only a very small percentage of the cases of consumption.

SANATORIUMS IN GREAT BRITAIN.

Though the open-air treatment has spread everywhere in Great Britain the number of public and private sanatorium beds is comparatively smaller than in Germany and, exclusive of Poor-law infirmaries, cannot exceed 3000, whereas Germany counts tens of thousands. This is chiefly due to the enormous increase of these institutions under the German Workmen's Insurance Act. We have some very good specimens in this country, as, for instance, King Edward VII. Sanatorium, founded by His late Majesty, an ideal establishment beautifully situated, and Frimley, the Brompton Hospital Sanatorium, well adapted for the working classes, to mention two among many others in the United Kingdom. These institutions are doing untold good, both in the way of treatment and instruction, and recent complaints against sanatoriums seem exaggerated and unreasonable, though they may partly be accounted for by the nature of the cases admitted, which are generally too advanced and fitter for consumption hospitals, and many more such hospitals are needed in this country.

A comparison has recently been made by Messrs. Elderton and Perry, under the auspices of Professor Karl Pearson, F.R.S., between the results from sanatorium treatment and those obtained in pre-sanatorium days by Dr. Pollock and myself. As far as I am concerned, I highly appreciate the care and attention which have been bestowed on my laborious figures, and I am pleased to note that Messrs. Elderton and Perry's conclusions agree so well with my facts; but I do not consider that sanatoriums have been long enough established in this country to furnish the information required for reliable statistics, and I hold that a fair and useful comparison is not yet possible. I would deprecate also comparison of America sanatoriums, such as the Adirondacks, with records of private patients in Great Britain, necessarily under different conditions.

I propose later to offer an opinion as to the needs of this country with regard to sanatoriums, hospitals, dispensaries, and labour colonies, but for the present will only say that the successes achieved at some of the working-class sanatoriums and the results of certain private sanatoriums justify a steady continuance of work which is first curative and secondly educational.

We note how the patient with a limited tubercular pulmonary lesion is removed to the thoroughly hygienic surroundings of a sanatorium and is compelled to live a healthy life, his food, his room, his exercise, his rests being all placed under minute direction. Here he slowly but gradually recovers, losing his symptoms, regaining his strength, until he is able to return home, where he presents himself not only fit to do work but to act as an apostle of fresh air and wholesome living.

GRADUATED LABOUR.

The introduction of a system of graduated labour into the treatment of consumption as a substitute for walking exercise has been an important addition and forms a prominent feature at Frimley, the Royal Victoria Hospital, Edinburgh, Maltings Farm Sanatorium, and at King Edward VII. Sanatorium.

Dr. M. S. Paterson,[13] who has introduced the system so successfully at Frimley, lays down as a condition of any work being undertaken that the patient's temperature shall not reach 99° F. in case of males, or 99·6° F. in case of females, and that if there be any rise of temperature after even the lowest grade of work the patient should be placed in a state of complete immobilisation until the register returns to the normal. It is found that after a few days the same grade is accomplished without rise of temperature, and in a week's time a higher grade is attempted with success, until by degrees the highest is reached and the patient is able to perform several hours of pick-axe, shovel, or wheelbarrow work without any unfavourable symptoms.

There are six grades of work besides walking, commencing with carrying small baskets of earth a certain distance and ending with pickaxe work, shovelling, hauling stones, and general heavy navvy work; while for the women patients the grades of exercise and work are similar, but the baskets and shovels are of smaller size and they are not allowed to work as hard as the men.

Dr. Paterson holds that in these working consumptives there occurs "an artificial inducement of auto-inoculations adjusted to the resisting power of the protective substances, and that it is possible to control the auto-inoculation by complete immobilisation." According to Sir Almroth Wright,[14] "it is by the agency of these auto-inoculations that the protective mechanism of the blood is set in motion, so that whenever bacterial products escape from localised foci and pass into the circulation, intoxication phenomena and immunising responses must necessarily supervene." Thus after inoculation from a tuberculous focus a large production of protective substance is calculated to take place. Whatever the theory may be to account for the change, it is most interesting to see patients become gradually accustomed to labour without any rise of temperature, and while the system does wonders for the bodies and especially for the muscles of our patients, it also has a most beneficial effect on their minds. Depression and gloom give way to cheerfulness and hope. The discovery that they can do honest work without suffering and that day by day their working powers increase has a most encouraging effect on their spirits, which rise proportionately with their returning strength.

TREATMENT AT HIGH ALTITUDES.

Probably one reason why sanatorium treatment was not more quickly taken up in this country was that, at the time, the attention of the medical profession was much occupied in considering the high altitude treatment of consumption, introduced to special notice by Sir Hermann Weber in his well-known paper read before the Royal Medical and Chirurgical Society on May 11th, 1869, which set us about investigating these climates and their effects. In the following summer I visited Davos, and through the kindness of the late Dr. Spengler and Dr. Unger I examined a number of German patients who had passed some months at an altitude of 5000 feet. At the time there were no English, though some had been there during the winter. What I saw of the patients and of the climate induced me to give a full trial to the high altitude treatment for consumption, and I have watched its effects on over 400 of my patients, sending them not only to the mountain resorts of Switzerland, such as Davos and St. Moritz, but also to North and South America and South Africa, and the statistics of most of these cases have been published in my Lumleian lectures delivered before this College on Aero-therapeutics. They confirm the results of Archibald Smith, Jourdannet, Guilbert, Lombard, and of Hermann Weber as regards mountain climate, of which the characteristic features are: (1) diminished barometric pressure and consequent rarefaction of the atmosphere; (2) diathermancy of the air, or the increased facility by which the sun's rays are transmitted; and (3) asepticity or freedom from pathogenic germs, as proved by the researches of Pasteur and others.

The effect of mountain air on the organs and functions of healthy and of sick persons has been ascertained by repeated careful observations to be as follows: the skin is tanned by the solar rays and, according to Dr. Bowles, principally by the ultra-violet rays, in the attenuated atmosphere. The circulation is at first quickened, the heart's impulse becomes more powerful, but the pulse-rate at the end of six or eight weeks falls to normal, or even below normal; the respiration is at first quickened, but after a similar interval it gradually slows and is reduced to normal or below normal. The breathing becomes deeper, the inspiration longer, and the expiration more complete, and thus is explained the slowing of the respiration. There is reduction in the blood pressure and in the amount of urea excreted by the kidneys, but more carbonic acid and water are eliminated by the lungs. When acclimatisation is complete the urea appears in full quantity in the urine, and the blood pressure again increases. Accompanying and exactly coinciding with the reduction in the pulse and respiration the thorax expands in several directions, causing an increase in circumference at various

[13] Auto-inoculation in Pulmonary Tuberculosis, by Marcus Paterson, M.D. 1911.

[14] Studies on Immunisation and their Application to the Diagnosis and Treatment of Bacterial Infections.

levels of from 1 to 3 inches and even more, also an augmentation of the spirometric record and increased mobility of the chest walls.

EFFECTS OF MOUNTAIN CLIMATES IN CHRONIC CASES.

The effect of mountain climates on selected cases of chronic tuberculosis is remarkable. Cough and expectoration vanish. There is considerable gain of weight, the general appearance is greatly changed for the better, and it is difficult to recognise in the bronzed and vigorous individuals the pallid invalids of a few months before. Muscular power is largely increased, and many of the patients walk 10, 15, or even 30 miles a day and climb mountains.

The local improvement is more striking. Tubercle bacilli are generally banished from the sputum. Respiration, at first increased in rate by the elevation, becomes deeper and easier. The physical signs show, in cases of consolidation, resonance over both lungs, the disappearance of all signs of dulness, bronchophony, and crepitation, and the substitution of harsh breathing, like the compensatory breath sound heard over the unaffected lung in pleuritic effusion.

In many of these earlier cases of consolidation the disappearance of the physical signs is so complete that the physician has to refer to his notes to discover which lung was originally attacked.

In softening and excavation cases the improvement takes the form of disappearance of moist râles and often of cavernous sounds, and hyper-resonance becomes evident owing to the large development of emphysema around the lesions.

Of all my statistics of consumptive patients the high altitude cases yielded the most favourable results and, what is most important, showed the fewest relapses.

The climate of high altitudes does most for the tubercular consolidation patients, for a large proportion of these become cases of arrest. Those with limited cavities do not derive the same amount of advantage as patients with only consolidations, though they also are much benefited.

I am glad to find that my favourable experience of the high altitudes is confirmed by the statistics of the Basel-Davos Sanatorium at Davos (5200 ft.). Comparison with the German sanatoriums before alluded to, the proportion of severe cases being much the same in both institutions, shows that the percentage of patients able to work five years after their discharge is to the advantage of the Swiss, the Swiss capables being almost double those from the German sanatoriums.

SERUM AND VACCINE TREATMENT.

I must now say a word on the treatment of consumption by anti-tuberculous serum and vaccines.

Many attempts have been made to produce an anti-tuberculous serum by inoculating with tuberculin animals believed to be immune from tubercle, and then using the serum of that immune animal for hypodermic injection into consumptive patients. This was done in France by Richet and Hericourt, by Bouchard, Daremberg and Bernheim, and by Marmorek, in Italy by Maragliano, and in the United States by Trudeau and Baldwin, Sternberg, and others, also by Dr. Horrocks and myself at the Brompton Hospital under the auspices of the Lister Institute, but though we all succeeded in obtaining a special serum and scored a certain amount of success this was never sufficient to warrant perseverance on a large scale on my part.

Vaccines, in the form of tuberculin, were started by Koch himself, as we know, in 1890, and the first form known as the old tuberculin had an extensive trial in most countries. This old tuberculin was pronounced to be a failure by the majority of observers and, according to the Brompton Hospital Report on the cases treated in the wards, the tuberculin caused breaking-down of the tubercular masses in the lungs and the formation of cavities, and even sometimes led to the extension of the disease; but it was noted later on that this appeared to be often followed by contractile changes due to increase of fibrosis. I was one of those who drew up this Report and I visited Professor Koch at Berlin to obtain his instructions as to the carrying out of the tuberculin treatment, so that the experiments should be fairly tried. My colleagues and I tested it both in hospital and in private practice, and came to the conclusion that it did more harm than good, and this was the general verdict, confirming that of Koch's own colleagues, Virchow, Gerhardt, von Leyden, Senator, and Ewald.

But it has since been suggested that Koch used too large a dose of tuberculin, producing a powerful reaction, which is better avoided, and that a smaller dosage is desirable. There are now several tuberculins, two of which, T.R. and B.E., have different effects from the old tuberculin of Koch, and these are generally employed in greatly reduced quantities. My colleague, Dr. Hector Mackenzie, who has a large experience on the subject, reports: "Whether one uses old tuberculin T.R. or B.E. for treatment the initial dose is about the same, 0·00001 c.c. This is given at intervals of two to eight days. If a local or general reaction occurs the interval should be increased and the dose diminished. The dose is gradually increased, avoiding reaction, until after some months, doses of 0·1 c.c. up to 1 c.c. can be given without local or general reaction." Bovine tuberculin is also used for cases of human tuberculosis.

There is still much conflicting evidence, and medical men are by no means unanimous as to the advantage of tuberculin treatment, yet the testimony of Trudeau, Bandelier, Moller, and Ritter indicates that carefully selected tubercular patients treated in a sanatorium with tuberculin make better progress than similar cases treated in sanatoriums without tuberculin.

It may be that tuberculin, which we know to possess a wonderful faculty for penetrating tubercular tissues, has also the power of exciting the anti-bodies in the neighbourhood, such as the opsonins and other protective substances and of stimulating their production, so that a system of defence is thereby organised. The fact that tubercle bacilli disappear earlier from the sputum during this treatment is very remarkable, and everything points to the necessity of further investigation in the matter. But such investigation ought to be carried on in a hospital or sanatorium rather than at a tuberculin dispensary, where there is no means of observing the effect of the tuberculin on the patient's system or of controlling the inoculations and their results.

EFFECTS OF IMPROVED HYGIENIC CONDITIONS.

To sum up, What are the prospects of the crusade against tuberculosis in this country, and how can we further them? We must bear in mind the blessed agencies of prevention which, when set in motion, go on pursuing their beneficent course independently of fashion and caprice. Such are improved drainage, more cubic space and less overcrowding, better food and more of it, more air and sunlight, cleanliness of house and person, and greater opportunities for play and exercise. It is probable that a large proportion of the two-thirds reduction in our phthisis mortality during the last 50 years is due to such agencies, and as the standard of public opinion is raised these ought to be more widely spread and to act more powerfully. What a splendid effect a good town-planning scheme ought to exercise on the public health! Then comes the education of all classes, including the children, by tuberculosis exhibitions and by popular lectures and tracts, which now permeate and enlighten the country, showing the people how they can help themselves. We may count on these hygienic, sanitary, and educational agencies to contribute effectively to the prevention of tuberculosis and to the further reduction of the phthisis death-rate.

MEANS FOR DEALING WITH CONSUMPTIVES.

And what is our means for dealing with the consumptive patient? The great difficulty, especially among the poor, is to detect and separate for treatment *early* cases of tubercular disease; and here, undoubtedly, the dispensary system introduced by Dr. R. W. Philip is of the greatest use, as home visitation of the consumptives and connecting them with philanthropic and other agencies is thus secured. Out-patient departments of consumption hospitals ought, if well organised, to fulfil the same functions, and it is possible in this way to classify the patients according to their requirements. For when we come to the consumptive patients themselves we most of us find that few are fit for admission into a sanatorium, and many require the care, treatment, and nursing of a hospital. The working classes, and especially those who have families to support, do not leave off work until compelled to do so from sheer inability or unless they have been early alarmed at the danger of persistence in their occupation. Consequently medical men when called in find they have to deal with cases of more or less active disease involving a considerable amount of lung surface and often in advanced stages. The consumption hospital is the proper place for such patients, where

they can be treated with all the approved methods of modern medicine and where they may in time improve sufficiently to be able to benefit by the sanatorium, or where if they deteriorate and sink, their last days can be passed in comfort. Another great advantage of the consumption hospital is that it isolates from the rest of the population those advanced and acute cases which are the most likely to become centres of infection.

England was the first country and London the first city to recognise the need for consumption hospitals, and our metropolis had established four special hospitals before other cities had done anything in the matter.

The sanatorium is intended to receive consumptives in early stages with limited lesions, free from pyrexia and able to take exercise. If such patients are submitted to the complete system of sanatorial treatment for at least six months, though often a longer period may be necessary, they frequently leave the institution with disease arrested, or greatly reduced, and are able to undertake work again. Where, as at Frimley, the mass of patients undergo, during their stay, training in various grades of labour, they generally return to their former occupation, if a healthy one, or change it, if unhealthy, for one more suitable.

Change of occupation is, however, one of the difficulties for the consumptive, for if he returns to an unhealthy calling he may have a relapse, and if he undertakes new and healthy work his earnings will probably be at first too small for his support. In the middle classes, which fill the King Edward VII. Sanatorium, the problem of providing healthy occupation has been largely overcome, and we get excellent reports from old patients who still carry out essential parts of their sanatorium *régime* in their different callings.

Besides home institutions we have now in the Queen Alexandra Sanatorium at Davos a high-altitude sanatorium where with sanatorium life the great advantage of mountain climate is combined.

I am convinced that any comprehensive scheme for dealing with consumption in this country should include the establishment of a large number of consumption hospitals scattered over the country in close connexion with dispensaries and sanatoriums and as a further link in the chain some form of labour colonies and exchanges should be available.

The task of further reducing and abolishing tuberculosis is not a hopeless one, but it does not lie wholly with the doctors. It lies also with those who have it in their power to remove or to lessen the principal causes of tuberculosis—viz., the overcrowding of our cities, the want of open spaces and ventilation, the insanitary houses, the lack of a good supply of water and of pure milk. If all these defects were remedied the number of phthisis cases would be comparatively small. The Government and the local authorities could insist, too, on the removal of advanced cases of consumption to a hospital or infirmary, and thus do away with one chief source of infection, and we should soon see a rapid fall in the number of contact cases and in the mortality tables.

BENEFACTORS DURING PAST YEAR.

And now at the close of my oration I must not forget to mention the benefactors to the College during the past year.

On Oct. 27th, 1910, the Medical Committee of Guy's Hospital, through Dr. Herbert French, presented to the College an excellent portrait of a former President and present Senior Fellow, Sir Samuel Wilks.

Among the books presented were seven valuable manuscripts and two printed books bequeathed to the College by the late Harveian Librarian, Dr. J. F. Payne. Dr. R. Crawfurd gave Prayer Books of Queen Anne and of George I., containing the Service for the Healing, two pamphlets on the King's Evil, and a silver touch-piece of James III., and other old and valuable books were presented by Dr. J. A. Ormerod, Dr. William Ogle, Sir Dyce Duckworth, Sir William Osler, and the present Harveian librarian.

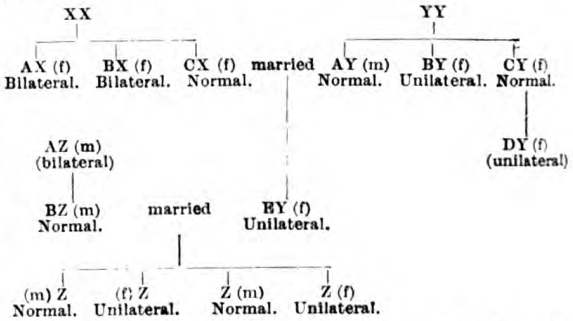
Sir George Sutherland Mackenzie, K.C.M.G., C.B., bequeathed, contingent on a life interest of his two brothers, a legacy of £30,000, free of duty, to the Royal College of Physicians and the Royal College of Surgeons for enabling them to assist students in scientific medical research.

I take this opportunity of recording my obligations to the Harveian Librarian, Dr. Norman Moore, and to the Registrar for kind help in preparing this oration.

I would conclude by exhorting the Fellows and Members of this College to continue in that mutual love and affection which Harvey enjoins, and I would offer my sincere thanks to you, Mr. President, for the great honour you have conferred on me in appointing me Harveian Orator, and to the Fellows and Members for giving me so attentive a hearing.

ON THE RESULTS OF THE MANIPULATIVE TREATMENT OF CONGENITAL DISLOCATION OF THE HIP-JOINT.

BY GEORGE C. E. SIMPSON, B.A., M.B. CANTAB., F.R.C.S. ENG.,



SURGICAL REGISTRAR AND TUTOR, ROYAL SOUTHERN HOSPITAL, LIVERPOOL.

CONGENITAL dislocation of the hip is a condition frequently met with in orthopædic hospitals, but not often seen in general hospitals, and the following short account of the results obtained in the Royal Southern Hospital, Liverpool, may prove of value by emphasising the great advantage of early recognition and treatment of the condition.

The etiology and anatomy of the condition and the main principles of the Lorenz method of treatment are fully described in many of the larger text-books and so only a few points of interest will be alluded to.

According to Hoffa,[1] congenital dislocation of the hip-joint is ten times as common as all the other congenital dislocations together; the cases amounted to about 1 per cent. of all cases in an orthopædic clinic. The condition is far more common in the female sex (87 per cent.) and about one-third of the cases are bilateral, the remainder being equally divided between the two sides.

There are several theories as to the cause of the condition; maldevelopment of the acetabulum and of the femoral head undoubtedly plays a large part and this is aided by muscular action or malposition in utero. Heredity can be traced in some few cases. Dupuytren[2] records a specially notable instance which seems to bear out the Mendelian theories, and is so interesting that I have put it in the form of a table. In the three intermarried families the condition occurred in 8 out of 16 individuals.

In the present series of cases there were three in which mother and daughter were involved, and one where distant cousins both came under treatment. The greater frequency in females is possibly accounted for by some difference in the pelvic girdle of the sex already present in fœtal life.

Anatomy.

In infants the changes are but slight; the acetabulum is not so well formed as usual, and the ligaments of the joint are relaxed. Dissections and radiographs between the ages of two years and seven years show that the head and neck of the femur are smaller than usual, the neck shortened and altered in direction, usually varoid and rotated forward. The epiphysis of the head is imperfectly rounded and displaced (usually upwards), its cartilage is irregular and imperfect. The acetabulum is smaller and shallower than usual, and often has a somewhat triangular shape; it is occupied by fat and fibrous tissue. The posterior and upper parts of the rim are most deficient, and a more or less definite groove leads from here to the irregular smoothed area

[1] Orthopædic Surgery, Stuttgart, 1902.

[2] Quoted by Jones and Ridlon, Contributions to Orthopædic Surgery, p. 332.

which marks the portion of the ilium which is in relation with the femur. The capsule of the joint is thick and roomy, and often has an hour-glass form due to a constriction which separates the acetabular portion from that occupied by the head of the femur; it is usually intact and so intervenes between the head of the femur and the periosteum of the ilium and prevents the formation of a false joint. The posterior ligaments are lax, the ilio-femoral is contracted; the ligamentum teres is usually present and much elongated. The muscles and fasciæ are altered in length, direction, and relationship, to suit the new conditions; the shortening of the hamstrings and adductors is specially important from the resistance it offers to reduction.

Careful consideration of radiographs at this period shows several interesting facts. In cases of unilateral dislocation it may often be noted that the head and neck of the femur of the sound side show in some degree changes similar to those shown on the side of the dislocation. The neck appears to be altered in shape and the epiphysis to be faulty. Further, the ilium seems to form a larger portion than usual of the acetabulum. In other instances the development of the pelvic bones on the dislocated side is seen to be inferior to that on the sound side; this is often well seen in the pubic and ischial rami which may remain largely cartilaginous to the age of 4 or 5.

These appearances give support to the theory that faulty development during intra-uterine life of the bones entering into the articulation is the cause of the condition. Malposition of the limbs or other intra-uterine factors might lead to dislocation and so to maldevelopment of bones on the dislocated side, but could not account for the associated maldevelopment of the bones of the opposite side. On the whole, the fault would appear to be on the part of the femur, pubis, and ischium, rather than on that of the ilium.

In older patients the change in the position of the head of the femur and the associated conditions become more marked. Trauma may intervene and cause rupture of the joint capsule, and if this occur the head of the femur may come into direct relation with the periosteum of the ilium and so lead to the formation of a stable pseudarthrosis. As the head of the femur attains a more dorsal position the relation of the centre of gravity of the body to the inter-femoral plane becomes altered. This naturally applies more markedly to bilateral cases, but is also present to some extent in unilateral cases especially when the patient is standing on the dislocated leg. The centre of gravity falls in front of the plane of support, and to remedy this the lumbar spine is strongly dorsiflexed, so moving the line of gravity back to the plane of support. The new position of the head of the femur and the associated alterations of the muscles combine to rotate the axis of the pelvis forward and downwards, and so increase the lumbar convexity, and may lead to an extreme degree of lordosis. In unilateral cases again the shortening of the dislocated limb is partially compensated for by tilting of the pelvis and lateral curvature of the spine. These conditions affect the growth of the vertebræ and so ultimately become fixed.

Symptoms.

The attention of the parents is usually attracted by the gait at the time the child commences to walk (which may be later than usual). In unilateral cases the child limps on the affected side; in bilateral cases the child walks with a characteristic rolling or waddling gait; lordosis is usually obvious. Examination in unilateral cases shows a shortening of the affected limb, which may in older patients amount to two or three inches; the trochanter is displaced upwards and backwards, and appears prominent (measurement of Bryant's triangle shows this best). Movements, active and passive, are free except abduction which is much diminished, and extension which may be slightly limited. The line of the foot is usually normal. Careful examination reveals on one or both sides the absence of the head of the femur from its normal position and its presence on the dorsum ilii. The latter is best observed with the child lying on its back or on the sound side and the limb somewhat flexed, adducted, and inwardly rotated. Finally, alternate traction and relaxation of the limb with the pelvis fixed gives an up-and-down movement of the femur—the so-called "telescoping."

In most cases the history of deformity from birth, the gait, and lordosis at once suggest the diagnosis, which is confirmed on examination by the freely moveable joint, the telescoping and the abnormal position of the head of the bone.

A radiograph should be taken in every case with the foot and leg well inverted to show the neck of the femur plainly; this not only settles the diagnosis but is of some assistance in prognosis, as it reveals the degree of development of the involved bones.

Prognosis.

Without active treatment no improvement is to be expected; the condition progresses throughout childhood, especially at periods of rapid growth. The deformity usually reaches its maximum development at about the age of 12 or 13. The limp or rolling gait and the lordosis make the patient self-conscious, and handicap them both physically and mentally throughout school life. They are readily tired by walking, and are unable to take part in games with other children, and so not only suffer in their physical and constitutional development but become shut off from the companionship of children of their own age. In addition in some cases the joints become painful after even slight exercise and tuberculous trouble is apt to supervene. In bilateral cases the limbs may become much adducted, and render the walk very conspicuous and disagreeable, and a scissor leg condition may be attained. In adult life the patients are at a disadvantage in obtaining employment—a disadvantage made the more serious by the Workmen's Compensation Act. In other ways, too, their physical deformity becomes a serious matter to that large proportion who are of the female sex. Apart from this, the joint itself may become the seat of arthritic changes which render any movement or pressure on the joint painful and practically incapacitate the patient; this is frequently the case after the age of 30, and may be so severe as to lead the patients to submit to severe operations in order to obtain relief. Fortunately the changes in the pelvis are not such as to lead to trouble during childbirth.

Prognosis with Treatment.

For the conditions arising after the age of puberty various treatments may be necessary (e.g., fixation by apparatus, osteotomy of the femur or pseudarthrosis), but these are beyond the scope of the present paper. No patient in these days should be left to grow up without the condition being recognised and an attempt made to rectify it at the earliest possible age.

Various treatments have been brought forward at different times, but that which should be tried in every case is the manipulative method—bloodless reduction—perfected by Lorenz.[3] This may be supplemented in some of the older cases by preliminary traction by weight or other apparatus. In unsuccessful or recurrent cases it may be supplemented by exploratory operation to discover and remedy any condition which is opposing reduction or interfering with its stability. Thus, an hour-glass contraction of the capsule may be divided, a shallow acetabulum deepened, or a lax posterior ligament shortened.

In a large proportion of cases treated by simple manipulation before the age of nine, a true anatomical reduction with full restoration of function is to be expected. In most of the remainder the head of the femur is moved forward from its unstable position on the dorsum ilii to a position either close to and above, or anterior to, the site of the true acetabulum. In this position the head is fixed by strong ligaments and muscles which pass over it, and a stable and mobile articulation is obtained, so rectifying the limp. The new articulation is close to the normal plane of gravity and so eliminates the lordosis.

In a few of the apparent anatomical reductions there is a well-formed acetabulum and a good joint, but the radiographs show that the acetabulum lies a little above its usual position, and is formed chiefly by the ilium. Physical examination of the patient shows that the trochanter is slightly raised and the head of the femur lies at a higher position than usual and can more readily be detected from the groin. The functional result in these cases is exceedingly good, often giving a limb practically equal to a normal one. I incline to think that these cases should be classified as true repositions, in which the aberrant level of the acetabulum is developed to suit the malformed and malplaced head of the femur.

[3] Manipulation had been used for some time, but had fallen into disuse. Lorenz re-introduced it and improved it, following the main principles described by Paci.

CASE TABLE I.—*Unilateral Cases.*

No.	Sex; age at operation in years; date of operation; number and duration of plasters; calliper duration.	Hip affected.	Movements, &c., at exam., 1909.	Measurements, 1909. Side.	Ant. sup. sp. to int. mall.	Umbilicus to int. mall.	Bryant's triangle. Vertical: horizontal side.	Circumference of thighs at corresponding parts.	Shortening compared to sound limb.	Functional capacity.	Telescoping.	Lordosis.	Skiagram and remarks.	Classification. Anatomical.	Classification. Functional.
					Inches.	Inches.	Inches.	Inches.	Inches.						
A.*	F., aged 12. Untreated. 1909.	Rt.	Flexn and addn. good. Extn. 10° short of full. Abdn. 20° allowed. Out rotn. very restricted. Toe points forward.	L.	26¼	29	2 / 2¼	—	1¼	Limp marked; walks and runs as well as a girl of 10. Limb does not tire readily (can walk 5 miles).	Very slight.	Very marked, quite 30°; Scoliosis.	Reduced after traction.	?	?
				R.	25½	27	½ / 3	—							
1	F., aged 3. 1903. Plasters 3, 6 mos.; call. 2 mos.	Rt.	Full free movts. in all directions; toe points forward.	L.	23¼	25	2½ / 2	—	—	No trace of a limp. Limb never gives any trouble.	—	—	Very well formed acetab. and head of femur; angle of neck normal.	Anat. reduct.	Perfect.
				R.	23¼	25	2 / 2	—							
2	F., aged 6. 1908. Plasters 3, 8 mos.; call. 8 mos. (Fig. 4).	Rt.	Full free movts. in every direction; toe forwards.	L.	26	28¾	1¾ / 3½	13½	¼	Slight trace of limp; walks and runs as well as other girls; can walk over 6 miles. Says she jumps better than others.	—	—	Well-formed head and epiphysis; good acetab.; well-formed joint; marked coxa vara.	Anat. reduct.	Perfect.
				R.	25¾	28½	1½ / 3¼	13½							
3	F., aged 5. 1908. Plasters 5, 8 mos.; call. 4 mos., still on.	Rt.	Still wearing call.; full extn. and abdn.; 100° flexn.; slight addn.; toe rotated out 20°.	L.	22¼	24½	2 / 2¼	12½	¾	Very slight limp; walks very well in calliper.	—	—	—	Anat. reduct.	Perfect.
				R.	21½	24¼	1¼ / 3¼	11¼							
4	F., aged 2¾. 1903. Plasters 2, 9 mos.; call. 1 yr.	Rt.	All movts. equal in range and power in the two limbs; toe points forward.	L.	25	28	2¼ / 3¼	14¼	—	No trace of a limp; buttocks quite symmetrical; drags foot a little when walking; walks, runs, jumps as well as her comrades.	—	—	Perfect reduction; perfectly formed joint.	Anat. reduct.	Perfect.
				R.	25	28	2¼ / 3½	14							
5	F., aged 7. 1908. Plasters 7, 12 mos.; call. now on.	Rt.	At commenct. of call. trmt. fair movt. already present; still stiff from plasters.	L.	23	24¼	2 / 2½	—	¾	No record.	—	—	—	Ant. reposn.	Probably excellent.
				R.	22¼	24¼	1¼ / 3½	—							
6	F., aged 4. 1908. Plasters 5, 12 mos.; 2 mos. allowed without call.	Rt.	Full extn., abdn., and addn.; only 100° of flexn.; foot rotated out 30°.	L.	19	21	2½ / 2½	11½	1	Slight limp; walks very well; calliper ordered for fear of accidents.	—	—	Good head and neck; good acetab.; well-formed joint.	Anat. reduct.	Perfect.
				R.	18	20	1¼ / 2¼	11							
7	F., aged 3½. 1904. Plasters 2, 9 mos.; call. 0.	Rt.	Full free movts. except extn., which is not quite full.	L.	22½	24¼	2 / 3	14	1	Slight limp; runs and walks well; seldom gets tired.	—	Slight.	(Lost.)	Dorsal disloen.	Very good.
				R.	21	23¼	1 / 3	13							

	F., aged 9. 1903. Plasters 3, 1 yr.; call. 1 yr.	Rt.	Addn. rather limited; 10° fixed flexn.; other movts. free and full.	L.	30½	32	2/3½	18	2¼	Limp marked; runs and walks well; tires rather easily.	—	Considerable.	Good acetab. above and overlapping true plane; coxa vara; head of femur poorly formed.	Anat. reduct.	Good.
				R.	28	31	¾/4	15½							
9	F., aged 3½. 1904. Plasters 2, 9 mos.; call. 4 mos.	Rt.	Some fixed flexn.; other movts. free and full.	L.	24	25	1¾/2	13	1¾	Limps; does not run much; tires easily.	½ in.	Marked.	No trace of any new acetab.; well formed head of femur on dorsum ilii.	Dorsal.	Poor.
				R.	22¼	24	¾/3	11½							
10	F., aged 5. 2nd cousin of Case 3. 1903. Plasters 3, 1 yr.; call. 6 mos.	Rt.	Full free movts. in all directions.	L.	27½	29½	2½/2	—	½	Slight limp; walks well; leg aches only after long walk.	—	Very slight.	Head of femur well formed and lies in a well-defined acetab. formed rather largely by ilium.	Ant. reposn.	Excellent.
				R.	27	29½	2/3	—							
11	F., aged 12. 1905. Plasters durn. 9 mos.; call. 6 mos.	Rt.	Some fixed flexn.; only 45° flexn. possible; full addn. and abdn.	L.	33	34½	3/3	—	3½	Considerable limp; scoliosis very marked; walks very well.	—	Considerable.	Good level but poor articuln.; poor development of head of femur.	Dorsal dislocn.	Poor.
				R.	29½	34	1¾/3	—							
12	F., aged 8½. 1903. Plasters 3, 13 mos.; call. 0.	Rt.	Abdn. and addn. full; flexn. to 100°; 10° fixed flexn.; int. rotn. limited; toe points forward.	L.	32	34½	2½/4	16	½	Limp slight; walks well; leg does not tire; delicate girl.	—	Slight.	—	Ant. reposn.	Excellent.
				R.	31½	34½	1½/4	13							
13	F., aged 12. 1907. Plasters 2, 1 yr.; call. 0.	Rt.	All movts. limited; flexn. to 125°; abdn. 20°; addn. 15°; fixed flexn. 15°.	L.	29¾	41¾	2¼/3½	16½	2	Limp considerable; scoliosis marked; walks fairly well and far.	—	Marked.	False acetab. in high position; poor head to femur; coxa vara.	Dorsal dislocn.	Poor.
				R.	27¾	41	0/4	14							
14	F., aged 5. 1903. Plasters 4, 1 yr.; call. 1 yr.	Lt.	Full free movts. in all directions; equal to normal limb; toe points forward.	R.	21	23	1¾/2¼	11	¼	Practically no limp; walks and runs well; leg does not tire.	—	—	Acetab. well formed, but roughened in appearance; head of femur poor; coxa vara; good reduct.	Anat. reduct.	Perfect.
				L.	20¾	23	1½/2¼	10½							
15	M., aged 2½. 1909. Plasters 4, 9 mos.; call. 3 mos.	Lt.	Still in call. therefore stiff; good abdn. and addn.; full extn.; 100° flexn.; toe points forwards.	R.	16½	19½	1½/2	10½	—	Walks well in calliper.	—	—	—	Anat. reduct.	Perfect.
				L.	16½	19½	1½/2	10							
16	F., aged 4. 1903. Plaster 1, 12 mos.; call. 1 yr.	Lt.	Full free movts., except slight limitation of abdn.; toe points forwards.	R.	25½	28¼	2¼/2½	15	—	Very slight limp; gets some pain on walking or running far.	—	—	Perfect acetab.; perfect head and neck; well reduced.	Anat. reduct.	Perfect.
				L.	25½	28½	2½/3	13¼							
17	F., aged 7. 1908. Plasters 5, 1 yr.; call. 3 mos.	Lt.	Still in call.; extn. and abdn. full; flexn. 100°; addn. a little limited; foot rotated 15° out.	R.	22	25	1½/2½	—	—	Still in call.; some pain after long use; crepitus perceptible in joint.	—	—	Very little epiphysis of femur; acetab. and head of femur roughened; arthritis; well reduced.	Anat. reduct.	Good.
				L.	22	25	1½/2½	—							
18	F., aged 4. 1904. Plasters 3, 1 yr.; call. 18 mos.	Lt.	Perfect full movts. in all directions; quite equal to normal limb.	R.	24	—	2½/—	—	1	Slight limp; wears raised boot; walks and runs well; leg does not tire.	—	—	Good head and neck in well-formed acetab., but invading ilium more than normally; very late development of ischium and pubis.	Ant. reposn.	Excellent.
				L.	23	—	1½/—	—

30	F., aged 3¾. 1903. Plasters 4, 16 mos. (Figs. 1, 2, and 3)	R.	Perfect free movts. in all directions.	24¾	31	2/2¾	—	—	—	Walks and runs well; takes part in games; often walks 10 miles.	Perfect articuln.	Anat. reduct.	Perfect.
		L.	Perfect free movts. in all directions.	24¾	31¼	2/2¼	—	—	—	Slight limp on left leg.	True reduct. but not quite as good as rt.	Anat. reduct.	Perfect.
31	F., aged 4. 1908. Plasters 8, 18 mos.	R.	Movts. and position good; a little stiff from plaster.	19½	22½	1/3	—	—	—	Likely to prove a perfect limb.	Head and neck of femur well formed; true acetab., well formed but slightly higher than left.	Anat. reduct.	Perfect.
		L.	Full flexn. and extn.; limb is abdn. 30° and out. rotn. 15°.	19¾	22¾	1½/3	—	—	—	Leg manipulated under anæsthetic; should prove perfect after massage.	A well-formed head, neck, and acetab.; true reposn.	Anat. reduct.	? Perfect.
32	F., aged 3. 1909. Plasters 3, 9 mos.	R.	Full free movts.; toe forward.	17	20	1/3	10¼	—	—	Should be perfect. Walks well; still slight waddle.	Good head and neck; good acetab. and well reduced.	Anat. reduct.	Perfect.
		L.	Full free movts.; toe forward.	17	20	1/2½	10½	—	—	Should be perfect.	Acetab. involves ilium rather more than in a normal joint.	Anat. reduct.	Perfect.
33	F., aged 2. 1907. Plasters 6, 12 mos.	R.	Good flexn. and extn., but some limitation of other movts.	24	26	1/1½	13	—	Very slight.	No limp; can run. Walks fair distance without tiring. Should be excellent.	No X ray. Head felt under artery; feels rather superficial and high.	Ant. reposn.	Excellent.
		L.	As right; toes turn in.	23½	25½	½/1½	12½	—	Very slight.	As right.	As right.	Ant. reposn.	Excellent.

In the class of anterior repositions the head is placed more forward in the groin and held apparently by ligamentous structures, no definite acetabulum being usually formed. The results in these cases are functionally but little inferior to those of true repositions. In a very few cases there is a good false acetabulum formed in this position.

In the few remaining cases the dislocation remains of the dorsal type; a fresh attempt may be made, aided if need be by open operation; even, however, should this course not be taken the condition of the patient is generally improved. In some cases a true false joint is obtained close to, but behind, the true acetabulum, and if this be the case the results may be excellent; possibly this results from rupture of the capsule during treatment. In other cases there are, as a general rule, a more stable limb with less limp and less lordosis than in untreated patients.

Treatment at the Royal Southern Hospital, Liverpool.

The cases recorded were treated at this hospital between 1901–1909: some of the earliest by prolonged extension and abduction in a Thomas frame, others by this method followed by the Lorenz method. Since 1903, when Lorenz gave a demonstration at the hospital, his method of treatment has been followed with but slight modification. The details and steps of the Lorenz method are described so fully in the larger text-books of surgery and orthopædics that only a few minor points followed in this clinic will be alluded to. In bilateral cases both limbs are reduced at one operation unless prolonged manipulation is required by reason of age or other difficulty. The plasters are usually closely moulded over a tight-fitting woollen garment, with small pads of wool over the sacrum and iliac spines. If much padding be used the limb may get re-dislocated. The patients are allowed to leave hospital within a week of operation and the parents are told to encourage them to use their limbs. This is facilitated if a strong toy horse or a low chair mounted on wheels be provided on which they can sit astride and propel themselves while still in plaster. The functional use seems to aid in keeping the joint intact and also in moulding and deepening the acetabulum, as Lorenz has pointed out. Every six or eight weeks (longer intervals, three to six months, were used at first) the plaster is reapplied; the limb being—under anæsthetic if necessary—brought down to a more normal position and at the same time inverted, care being taken not to allow a re-dislocation. In from 7 to 12 months the fully extended normal position is attained and, after a further 6 to 8 weeks in plaster in this position, a Thomas calliper splint is fitted and the child wears this for about six months longer, to keep the joint firm while it is first used. Massage and passive movement at this time greatly improve the functional result. In applying the new plasters care is taken to overcome the torsion of the limb and so bring the foot into good position and line; by this means some of the advantages of Lovett's inverted position seem to be gained. In none of the present cases, however, has that method been used, though it is now being tried in some cases.

Dangers of the Operation.

The patients suffer somewhat from shock, but so far there have been no deaths at this hospital from this cause. Bruising and swelling of the ruptured muscles may be troublesome. In older children fracture of the neck of the femur and separation of the epiphysis may occur, as happened in Case 23. This is avoided by care in manipulation and by carrying out the reduction if necessary in two or more stages, extension by apparatus being used in the interval. Plaster sores rarely give rise to trouble.

Note on Royal Southern Hospital Cases.

All patients treated from 1902 to 1909 were communicated with and asked to come up for examination in 1909. Many from change of address could not be traced and others lived at too great a distance to come. Of the 70 cases found in the register whose treatment was completed, 33 reported, and the condition is recorded in the tables. Particular attention was paid to the amount of shortening, the limits of mobility, the axis of the limb, to the gait and attitude, and to the functional value of the limb. Radiographs were taken of nearly all the cases, and a few typical ones are reproduced.

Of 90 cases in all seen from 1902 to March, 1910, 75 (83·3 per cent.) were girls and 15 (16 6 per cent.) boys. Of 60 cases in which it could be determined from the registers, 23 (39 per cent.) were bilateral, 19 (31 per cent.) right, and 18 (30 per cent.) left cases. (See Case Tables I. and II.)

Analysis of Cases and Results.

The 33 cases reported include 40 joints; treatment was commenced at ages from 2 to 12 years; a few are still wearing their callipers, others have been free from treatment for five or six years. The following table shows the anatomical and functional results:—

TABLE I.—*Anatomical and Functional Results.*

Functional result.	Anatomical results.			Total.	Per cent.
	Perfect anatomical reduction.	Stable anterior reposition.	Dorsal dislocation.		
Excellent.	18	9	—	27	67·5
Very good.	—	—	2	2	5·0
Good.	2	—	2	4	10·0
Fair.	—	—	3	3	7·5
Poor.	1	—	3	4	10·0
Total	21	9	10	40	—
Percentage...	52·5	22·5	25·0	—	100·0

In five cases, however, the patients were over 9 years old at the time reduction was attempted, and if these be excluded the figures read:—

TABLE II.—*Anatomical and Functional Results, excluding Five Cases in which the Patients were over 9 years of age.*

Functional result.	Anatomical results.			Total.	Per cent.
	Perfect anatomical reduction.	Stable anterior reposition.	Dorsal dislocation.		
Excellent.	18	9	—	27	77·2
Very good.	—	—	2	2	11·4

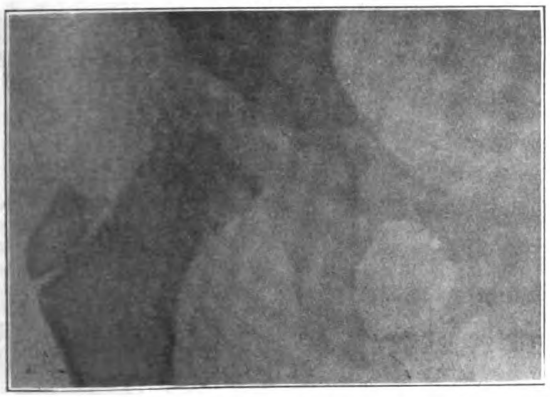
Conclusions.

1. Congenital dislocation of the hip is a condition which progressively gets worse till puberty and may cause severe deformity. In adult life further trouble may arise and completely incapacitate the patient.

2. Treatment by manipulation at the earliest possible time after infancy may be expected to yield a stable articulation with perfect function in 60–70 per cent. of cases. A slight



[4] Congenital Dislocation of Hip-joint, London, 1910.

FIG. 5.

Skiagram from Case 26, showing a good result, but persistent dorsal position.—1909.

Notes to illustrate method of classification.—CASE 30 (Figs. 1, 2, and 3).—Girl, aged 3 years and 9 months. Double dislocation. Treatment, 903; plasters 16 months. The legs are equal in length and there is full normal movement in all directions. The child limps slightly on the left leg, walks and runs well and takes her part in games. There is no telescoping or lordosis and the case is classed as a perfect anatomical and functional cure. CASE 2 (Fig. 4).—Girl, aged 6 years. Right dislocation. Treatment 1908; plaster 8 months; calliper 8 months. There is one-quarter inch of shortening, but no wasting of the limb. There is full normal movement in every direction and the toe points forward. The child limps slightly, walks and runs as well as girls of her own age, and says she jumps better. The joint is well formed but there is definite coxa vara. Perfect anatomical and functional cure. CASE 26 (Fig. 5).—Girl, aged 4 years. Left dislocation. Treatment 1902; reduction effected by prolonged extension and abduction in a Thomas's frame; plaster 6 months. There is 1½ in. of shortening, largely compensated by scoliosis. The movements of the joint are practically perfect, but the toe points outward. The limb is an inch less in circumference than the sound side; there is no telescoping but considerable lordosis. The child limps slightly, walks and runs well, but the left leg tires more readily than the right. The head and neck of the femur are well formed; the head lies in the horizontal plane of the acetabulum but slightly behind it. Persistent dorsal dislocation with fair functional result.

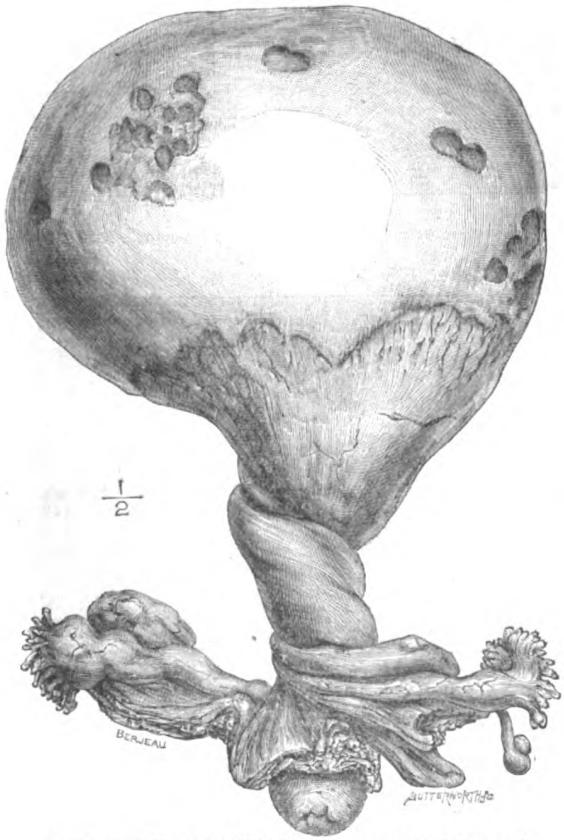
limp (due to imperfect growth of the bones) and some slight limitation of movement may remain, but the children are cured of any obvious deformity or incapacity.

3. Of the remaining 35–40 per cent. the condition is usually much improved by treatment.

4. The treatment in children below 8 years of age is attended by little or no danger and by few unfavourable accidents. The trouble caused to the parents is slight and the loss of school attendance in early childhood is of but small importance.

5. In children between 9 and 12 years of age treatment by manipulation has greater dangers and inconveniences and gives much less favourable results. It should, however, be tried in all cases which have unfortunately reached this age with the condition unremedied; great care and gradual reduction avoid the dangers of shock and laceration and considerable improvement is usually effected.

6. In unsuccessful and relapsed cases some form of open operation may prove of advantage.



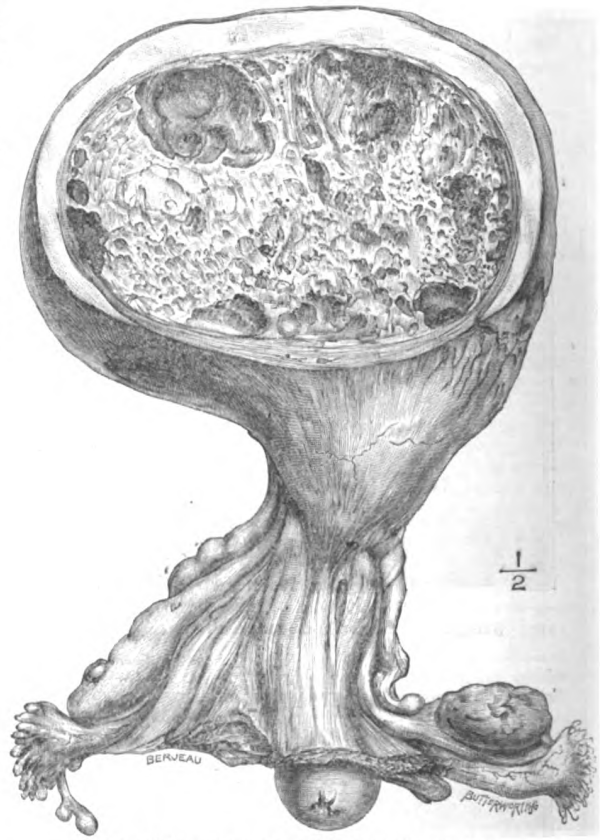
Finally, I wish to take this opportunity of thanking Mr. Robert Jones for allowing me the opportunity of using the material of his clinic for the purposes of this paper, and also for his kind assistance and advice in its compilation.

ON A CASE OF AXIAL ROTATION OF A FIBROID IN WHICH THE UTERUS WAS INVOLVED IN THE TWIST.

BY JOHN BLAND-SUTTON, F.R.C.S. ENG.,
SURGEON TO THE MIDDLESEX HOSPITAL.

ALTHOUGH it is well known that any abdominal viscus (except the liver) may undergo axial rotation, this accident has been chiefly studied in connexion with ovarian tumours.

FIG. 1.



A subserous fibroid which had undergone axial rotation and involved the uterus in the twist.

The symptoms produced by this abnormal movement are often so clear and pronounced that the condition is occasionally diagnosed with absolute certainty. Uterine fibroids are liable to rotate, but few cases have been recorded, and very few specimens with twisted stalks have been preserved. Such an accident to a fibroid is probably rare because the conditions most favourable to its occurrence—namely, a tumour of moderate size attached to the uterus by a long and slender pedicle—are uncommon. Fibroids, however, sometimes rotate when their connexions with the uterus would seem absolutely to preclude such a movement, as when a fibroid is sessile on the uterus; in such a circumstance the uterus becomes the pedicle and undergoes torsion. I have recently had an opportunity of studying a specimen of this kind at the Middlesex Hospital.

A spinster, aged 67, sought medical advice on account of pain, discomfort, and frequency of micturition, associated with a large tumour which could be felt in the hypogastric region. It had the clinical features of a uterine fibroid. When exposed in the course of the operation performed

FIG. 2.

The fibroid shown in section with the parts untwisted.

for its removal, the tumour proved to be as big as the head of a new-born child. The anterior surface of the fibroid was pearly white in consequence of a deposit of fibrous tissue, probably produced by the friction of the tumour against the abdominal wall. On withdrawing the tumour from the belly the pedicle was found to be twisted like a rope; on untwisting it the ovaries, Fallopian tubes, and uterus were recognised. Subtotal hysterectomy was performed, and after removing the parts I re-torsioned the pedicle to the same degree as before removal. The specimen was fixed to a flat cork and hardened in a solution of formalin for preservation. The fibroid had undergone degenerative changes coincident with age, I think, and in no way a consequence of the torsion of the pedicle. The thickness of the tissue forming the "milk white patch" on the surface of the fibroid proves it to be an old tumour.

The specimen with the pedicle twisted is preserved in the Museum of the Royal College of Surgeons of England. In the drawings the parts are represented twisted and untwisted. It is conceivable that the involvement of the uterus was due to, if, indeed, the whole movement was not facilitated by, its atrophic condition, and it is probable that the paucity of the

symptoms depended on the senile condition of the uterus. I know that torsion of the pedicle of a stalked fibroid will lead to very acute symptoms, for I exhibited and described such a specimen [1] (which is also preserved in the Museum of the Royal College of Surgeons of England) in which they were as severe as any I have noticed in association with ovarian cysts and tumours, and in spite of the fact that the fibroid was partially calcified.

Cases have been reported in which an ovarian cyst with a short broad pedicle has rotated and involved the uterus in the twist. In such a case the conditions would be almost parallel to those prevailing in the patient the subject of this communication. All in all, I am sure that the axial rotation of a uterine fibroid above the size of a walnut is a rare accident.

Brook-street, W.

ACUTE RHEUMATISM AMONG CHILDREN:

AN INQUIRY INTO THE PREVALENCE OF ACUTE RHEUMATISM AND ITS CONSEQUENCES AMONG CHILDREN OF SCHOOL AGE.

BY FREDERICK LANGMEAD, M.D. LOND., M.R.C.P. LOND.,

ASSISTANT PHYSICIAN, ROYAL FREE AND SEAMEN'S HOSPITALS; AND PHYSICIAN TO OUT-PATIENTS, PADDINGTON GREEN CHILDREN'S HOSPITAL.

IT is uttering a platitude to say that acute rheumatism is one of the commonest diseases of children which the medical man is called upon to treat. Yet the incidence among the community at large of a particular affection is often erroneously estimated by those who see only sick patients in hospital or elsewhere. The proportion of rheumatic children attending hospital to those suffering from other diseases is, without doubt, an index of the gravity of the infection, but it gives no guide to the amount of detectable rheumatism, or to the frequency of defects consequent on rheumatism, which may be present in those considered at the time to be in good health. A good example of the discrepancy between conclusions based on hospital figures and those obtained by the examination of school children is found in the case of tuberculosis, for this disease, though very prevalent among hospital children, is rarely detected in the examination of children at school; so rarely, indeed, that out of 1670 unselected school children examined by Dr. J. E. Squire and Dr. Annie Gowdey only 4·4 per 1000 were found to be definitely tuberculous. Remembering this and similar discrepancies, I have endeavoured to temper my views gleaned from hospital experience by an inquiry into the amount of detectable rheumatism among children attending the ordinary elementary schools of the London County Council.

Altogether 2556 children have been examined in four schools. These were in no sense selected. In three of the schools every child was examined; in the other, children who had arrived at certain periods of their school life were examined in accordance with the requirements of the education service. Of the total 2556, 844 were boys and 838 girls in the senior departments—i.e., from 6½ to 14 years old; and 874 were attending the infants' department, and consisted of nearly equal numbers of boys and girls from 3 to 6½ years old.

Method of procedure.—Each child was stripped to the waist, and the heart was carefully examined by the usual methods, any deviation from the normal either in size or action being noted. Other evidences of rheumatism were looked for. The size of the tonsils was recorded in figures, +1 implying slight enlargement, +2 considerable enlargement, and +3 very great enlargement. If adenoids were present in the absence of enlarged tonsils and were sufficient to cause signs of obstructed breathing, this observation was also noted down. An inquiry was made of the child, and of the mother when she was in attendance, for previous rheumatic manifestations in the child or for rheumatism in the family. When from the examination it seemed probable that the child was the subject of rheumatism, if the mother was not present, a nurse afterwards called at the home to make the same inquiries. This article is based on the data so obtained.

[1] Transactions of the Obstetrical Society, 1904, vol. xlvi., p. 149.

Number of Definitely Rheumatic Children.

Fifty-nine boys and 74 girls could be classified as definitely rheumatic, a total of 133. This is equivalent to a percentage incidence of 5·20 for children of all ages attending school, or of 6·83 for children in the senior departments only, those attending the infants' department being excluded from the estimation. The number affected at the different ages, and the percentage of rheumatic children at each age, are best shown in the accompanying table:—

Age in years.	3	4	5	6	7	8	9	10	11	12	13	14
Number of rheumatic children	1	1	4	9	16	11	11	21	13	23	22	1
Number of children examined	54	164	290	297	281	231	241	217	247	222	246	29
Percentage of rheumatic children... ...	*	0·60	1·37	3·03	5·68	4·76	4·56	9·67	5·26	10·60	8·94	*

* The number of children at the ages of 3 and 14 was too small to work out a percentage incidence of rheumatism which would be even approximately correct.

In the majority of cases attention was drawn to the rheumatic child by the condition of the heart—sometimes by definite valvular disease, at others by dilatation accompanied by such alteration in sounds and rhythm as one is accustomed to hear in rheumatic children. I need scarcely say that dilatation, weak cardiac sounds, or arrhythmia, by themselves were not accepted as sufficient evidence of active or past rheumatism; but children showing such manifestations were only accounted rheumatic if there was strong enough collateral evidence to remove all reasonable doubt. For example, a little boy aged 7½ years was found to have a deep cardiac dulness reaching nearly 2 inches outside the left nipple line, and weak cardiac sounds unaccompanied by a bruit; he was only considered rheumatic because it was elicited that he had been subject to growing pains, his brother had had rheumatic fever twice, chorea, and tonsillitis, and his mother chorea. Another patient, a girl aged 9½ years, who had fainted frequently and whose heart missed one beat in about every four, was included among the rheumatic cases, because she had had frequent tonsillitis and both her mother and brother had had rheumatic fever.

By requiring such definite evidence as this it is clear that one is likely to include too few rather than too many cases. Again, there are some rheumatic manifestations which, although very common, cannot be ascribed with certainty to rheumatism, in the absence of other data. Anæmia, for example, although an important and common consequence of rheumatism, and probably often occurring alone as the result of that disease, would not under those circumstances be recognised as rheumatic in origin. The same may be said of tonsillitis. Growing pains also, although undoubtedly rheumatic, make so little impression on the parents and are so readily forgotten or confused with the vague pains which herald or follow other acute febrile disturbances, that a history of their occurrence cannot be accepted as adequate evidence of rheumatism. Yet it is probable that growing pains not infrequently form the only manifestation of rheumatism in childhood. For these reasons it is almost certain that the percentage I have given above is well within the mark.

The table shows, broadly speaking, that more and more children become rheumatic as they grow older. There is, however, an apparent accession of rheumatism at the age of 10 which is not shown in the figures in subsequent years. I can give no explanation for this, and regard it as an inaccuracy which would have disappeared if a large enough number of children had been examined.

Incidence of Rheumatic Heart Affections.

I found that out of 133 children whom I had been able to classify as rheumatic, all except 18 showed some evidence of cardiac disorder at the time of examination. Thus rheumatic heart affection occurred in 4·49 per cent. of the children of all ages attending school, or in 5·94 per cent. of those in the senior departments only. Obvious valvular disease was found in 2·93 per cent. of children at all ages, or 3·92 per cent. of those in the senior departments.

An analysis of the 115 cases of heart affection showed that they were constituted as follows:—

Mitral regurgitation	44
Mitral stenosis	15
Double mitral disease	9
Probably double mitral disease, but one lesion doubtful	6
Aortic regurgitation and mitral stenosis	1
Dilatation with a systolic bruit at the apex, possibly mitral regurgitation	12
Dilatation with a short presystolic rumble, or so-called reduplicated second sound (mid-diastolic bruit), possibly early mitral stenosis	8
Dilatation without bruits	20

The comparative rarity of aortic regurgitation in children is emphasised by the fact that only one case was discovered among the 2556 children examined.

It will be observed that I have hesitated to group those children whose hearts were dilated and in whom only slight bruits—systolic, presystolic, or mid-diastolic—were heard. Each of these murmurs may be so transitory in rheumatic children that it is often quite impossible to say which are endocardial and which myocardial in origin. Moreover, it is a moot point how often early valvular disease is recovered from, and the discovery in rheumatic children of a murmur which afterwards goes does not necessarily mean that it was due to dilatation merely. Time may prove that a very slight systolic bruit at the apex in a child apparently in good health was a sign of the beginning of a slowly acquired mitral regurgitation; whilst a distinct presystolic bruit which used to be considered definite evidence of mitral stenosis may completely disappear, but whether it was produced by a temporary partial occlusion of the mitral orifice or was myocardial is debateable.

It has more and more been borne in upon me during the collection of these data, how frequently what appears to be a case of simple dilatation or cardiac weakness proves on investigation to be rheumatic. In fact, nearly every child with a dilated or weakly acting heart who was able to attend school, unless the condition was merely transitory, was a rheumatic subject.

Other Rheumatic Manifestations.

Chorea did not appear among the children or in the histories of their previous illnesses as often as might have been expected. There were 18 cases only, which amounted to 0·70 per cent. of the children of all school ages or 1·06 per cent. of the children in the senior departments. The comparative incidence in boys and girls followed the usual rule, there being twice as many girls affected as boys. Thus 0·71 per cent. of the boys were at some time choreic, and 1·43 per cent of the girls.

Relative Frequency of Rheumatic Manifestations.—The relative frequency of such rheumatic manifestations as could be investigated appeared to be as follows:—

Manifestation.	Number of cases.	Percentage of children.	Percentage of rheumatic cases.
Polysynovitis	42	1·64	31·57
Heart affections	115	4·51	86·46
Growing pains	35	1·37	26·31
Tonsillitis	32	1·25	24·06
Chorea	18	0·70	13·54

No reliable data were obtained in 10 cases.

As has been stated above, the percentage of the fleeting and consequently easily forgotten forms of rheumatism is probably far below the true average, whilst no data of value could be obtained of certain rheumatic manifestations like anæmia.

Enlarged tonsils and adenoids.—The relation of enlarged tonsils and adenoid vegetations to rheumatism in childhood is well illustrated by the figures obtained. Taking the 133 rheumatic cases, in 75 there were no signs of abnormality in the throat, in 21 the tonsils were slightly enlarged, in 11 considerably enlarged, in 16 greatly enlarged, and in 3 tonsillotomy had been performed before the patients were examined. Adenoids were responsible for producing signs of post-nasal obstruction and mouth-breathing in 7. In other words, there was an abnormality of the tonsils or pharyngeal mucosa or both in 58 cases, or in 43·6 per cent. of the rheumatic cases. This was sufficient to warrant operative interference in 37 cases, or 27·8 per cent. of the rheumatic cases.

It is interesting to compare these figures with those indicating the average frequency of tonsils and adenoids in school children generally. According to Macleod Yearsley, 7 per cent. of all school children require operation for this condition, whilst the medical officer of the Board of Education, from the results of the examination of 5,000,000 children, found that the percentage came out at 8. Therefore the incidence of tonsils and adenoids large enough to require operation is nearly four times as great in rheumatic children as in school children generally. Whether the abnormal tonsils permit the ingress of the rheumatic micro-organism, or whether they are the result of rheumatic tonsillitis, is a question which cannot be answered at present.

Remarks.

From this inquiry it is clear that there is a large amount of disregarded rheumatism among the children of school age in London. With the knowledge that about 1 in every 15 children from the age of 7 onwards attending the elementary schools is rheumatic, and that about 87 per cent. of these have some consequent affection of the heart, we may well consider what may be done to remedy this serious condition of affairs.

It must be remembered that nearly all the cases recorded in this article were of children who were considered to be in ordinary health, those ill enough to be removed from school or sent to a physically defective centre not being included. In very few instances did the parents or teachers know that the child was rheumatic or that the heart was affected, and no sort of precaution was being taken either to safeguard the heart or to prevent a recurrence of attacks.

The rheumatic children of the poor cannot get adequate treatment at present. For them, during the active stage of the disease, complete rest is essential, extending over a much longer period than they can be allowed to stay in hospital. They are not suitable for convalescent home treatment, since if once out of bed they are usually just as well at home. The result is that many of these children are discharged, with the disease no longer acute yet still smouldering on, to leave behind ultimately a damaged and crippled heart with all its attendant consequences. In many other instances the disease is so insidious in its onset and undemonstrative in its progress that the children do not obtain medical advice or treatment until permanent injury has been effected.

The routine medical examination of school children will enable the school medical officer to bring these rheumatic children to the notice of their parents and teachers, and so help to obtain for them, when necessary, such remedial treatment as is possible. When, moreover, the time for curative treatment has passed we may so influence their school life and choice of occupation on leaving school as to make the defect of as little moment as possible to its possessor.

Queen Anne-street, W.

ACUTE ENDOCARDITIS CAUSED BY A MICRO-ORGANISM HITHERTO UNDESCRIBED.

BY A. T. NANKIVELL, M.D., B.S. LOND., L.R.C.P. LOND., M.R.C.S. ENG., D.P.H. CAMB.,

ASSISTANT MEDICAL OFFICER, CROYDON BOROUGH HOSPITAL; AND DEMONSTRATOR IN PUBLIC HEALTH LABORATORIES, KING'S COLLEGE, UNIVERSITY OF LONDON.

A LITTLE girl, 3½ years old, was admitted to the Croydon Borough Hospital on Feb. 1st of this year. She was suffering from a mild attack of scarlet fever without severe throat symptoms. Her illness ran a normal course towards convalescence. But three weeks after admission she began to have rises of temperature in the evenings. At first the heart sounds were natural; later she developed a slight but definite double mitral murmur; the heart was appreciably enlarged. During the first week in March the temperature oscillated between 99° and 101° F. There was no splenic enlargement nor any sign of infarction elsewhere; the patient had no joint pains, nor were there any rheumatic

nodules present. The temperature chart was typical of an acute endocarditis. On March 7th I performed a venipuncture into the left median basilic vein, and obtained 5 c.c. of blood. The blood was inoculated into two broth tubes, and from one of these the diplococcus of which I shall speak presently was obtained. The after-history of the patient requires little comment; gradually the temperature subsided, and a fortnight later it had regained the normal level. The heart sounds remained unaltered, and there were none of the later lesions associated sometimes with endocarditis. The patient was removed from the hospital by her relations on March 25th.

The diplococcus which I obtained from the patient's blood stream showed no evidence of having a capsule. In shape each coccus was round, the size being about 0·7μ by 0·7μ. There was no tendency to chain formation, either in broth or on solid media. The organism showed no evidence of a hilum. It was non-motile. It had neither spores nor flagella. Its thermal death-point was 58° C. This diplococcus does not retain the stain by Gram's method—it is Gram-negative. It stains well with dilute carbol-fuchsin and eosin, less brilliantly with the blue dyes. It is not acid-fast.

On nutrient agar the diplococcus grows well at 37° C. and fairly well at 20–22° C. At 42° C. on agar the growth is only slight. The growth on agar has a ground-glass appearance, with small translucent separate colonies at the edges of the streak. The organism does not readily die, and will survive on agar for at least 12 weeks without subculturing. The diplococcus will grow both anaerobically and aerobically. It liquefies gelatin. It grows well in broth and peptone water, forming a precipitate; in peptone water it produces indol at the end of a week's growth. On Conradi-Drigalski medium and on Rebipelagar the diplococcus grows feebly, forming white, pin-point, translucent colonies. Litmus milk is clotted and turned acid by the diplococcus in 48 hours; the clot is firm and not honey-combed, and the supernatant whey is clear. The organism ferments glucose, with the production of acid, but no gas. Lactose, sucrose, maltose, galactose, raffinose, arabinose, mannite, dulcite, inulin, salicin, and dextrin are not affected. The diplococcus is not hæmolytic. The acidity and alkalinity of the culture media do not influence greatly the growth of this micro-organism. It grows well on agar between + 45 and − 60 (Eyre's scale). Outside these extremes the growth is more feeble. The organism is inhibited by 1 in 40,000 malachite green.

This diplococcus does not seem to be very pathogenic. The little girl from whose blood it was obtained was at no time very ill, nor did it produce any ill-effects when injected into guinea-pigs. I have to thank Professor R. T. Hewlett, who conducted the inoculation experiments for me.

At the time of the discovery of the diplococcus I had some thought that it might be the causative organism of scarlet fever, but I may say at once that this is, in all probability, not the case. I undertook a long series of agglutination and complement fixation reactions, using this organism with the blood from many scarlet fever patients, but in all these tests the results were negative. The micro-organism grows fairly well on agar to which has been added 1 in 4000 methylene blue, a medium which inhibits most other cocci. I plated many throat swabs from scarlet fever patients on to this medium, but never once succeeded in isolating this diplococcus from such cases.

Diplococci have been obtained from the blood and joints of patients suffering from rheumatic fever and acute endocarditis by Poynton and Paine,[1] Ainley Walker,[2] Triboulet,[3] Beattie,[4] and Wassermann.[5] Most of the diplococci described by these writers seem to have been Gram-positive, and differed in other ways from the organism I have isolated. W. v. Lingelsheim,[6] in a long paper, describes many varieties of rare Gram-negative diplococci; but no one of these appears to agree in all respects with the diplococcus which is the subject of this article.

My thanks are due to Mr. G. N. A. Hall, who has kindly examined many of the properties of this diplococcus, and helped to verify my observations on it.

SPINAL ANÆSTHESIA IN EGYPT.

BY H. E. S. STIVEN, M.A., M.B., B.C. CANTAB.,
REGISTRAR, KASR-EL-AINI HOSPITAL, CAIRO.

SOME extracts from the Kasr-el-Aïni Hospital Report for the year 1910 may be of interest to surgeons and anæsthetists. This hospital is a Government native hospital of about 500 beds. Here is also the Egyptian School of Medicine. The number of in-patients treated in 1910 was 8725. The total number of operations performed was 3205.

The most notable feature with regard to operations in 1910 is the great advance which stovaine has made as a routine anæsthetic. In the general theatres the operations under stovaine exceed those under general anæsthesia. The figures are: stovaine, 662; general, 599. No untoward results are recorded, and the chief danger seems to be a lowering of the general blood pressure during the operation. In the majority of cases this can be remedied by the administration of adrenalin. Stovaine did not produce its customary effect in at least 16 cases, which, therefore, had to be done under a general anæsthetic. Operations were finished off under chloroform in at least four cases. A successful administration of "high stovaine" was accomplished in 17 cases.

In the gynæcological theatre only 19 cases were given a general anæsthetic out of a total of 201 patients operated upon. Details were carefully kept in this theatre, and 175 cases were successfully operated on under stovaine. In 8 cases a general anæsthetic had to be administered after the injection of stovaine, either because of the insufficient anæsthesia produced or to check vomiting when the peritoneum was pulled upon. Eleven cases had a general anæsthetic from the commencement. Seven cases, which I have not counted as having a general anæsthetic, required a little chloroform towards the end of the operation, as the effect of the stovaine was beginning to wear off. The longest time a patient was under stovaine in this theatre without any chloroform being necessary was two hours and a quarter: this was a patient with malignant disease on whom a Wertheim's operation was being performed: stovaine (0·08 gm.) was given at the commencement and repeated half-way through the operation. The average length of time the anæsthesia lasts is about one hour and a quarter, but patients vary considerably.

The total statistics for anæsthetics in all the operating theatres shows: general anæsthetics, 1604; stovaine, 867; local anæsthetics, 633; somnoform, 126. The large majority of general anæsthetics is accounted for by the fact that 384 eye operations and 502 operations in the Cushaks (the minor operating theatres attached to the wards) were done under general anæsthesia.

I understand that two members of our staff are compiling a paper giving their detailed observations and conclusions. We look forward with interest to its publication.

I have to thank Dr. H. P. Keatinge, the director of the Hospital and Medical School, for his permission to publish these notes.

PRESENTATIONS TO MEDICAL PRACTITIONERS.—At Port Isaac (Cornwall) on Sept. 30th, Mr. Richard Julyan George, M.D., C.M. Edin., D.P.H. Irel., was presented with a silver table centrepiece and vases, together with an album containing the names of the subscribers, which numbered over 300, on the occasion of his leaving Port Isaac after practising for over 20 years in the district.—At Clovelly (Devon) on Sept. 30th, the members of the Clovelly Mariners' Union Society presented Mr. Robert Walker, F.R.C.S. Edin., L.R.C.P. Edin., with a substantial cheque on the occasion of his retiring from active work and leaving Clovelly. The members of the Rechabite Friendly Society gave Mrs. Walker a handsome dressing-case.—At the Parish Room, Wotton-under-Edge, Gloucestershire, on Sept. 28th, Mr. James George Boyce, L.R.C.P. & S. Irel., was presented with a cheque for £32, and an illuminated album containing the names of 170 subscribers, on the occasion of his leaving the town, after 20 years' residence, for British Columbia. Mrs. Boyce was presented with a handsome box of gloves.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

NOTES ON A CASE OF ACUTE GLAUCOMA SUCCESSFULLY TREATED BY THE OPERATION OF TREPHINING THE SCLERA.

BY SYDNEY STEPHENSON, D.O. OXON.,
OPHTHALMIC SURGEON, QUEEN'S HOSPITAL FOR CHILDREN, ETC.

THE suggestion of employing a small trephine to drill a hole in the coats of the eyeball in cases of glaucoma is by no means new, although it has never been widely adopted. Dr. Argyll Robertson[1] 35 years ago recommended such an operation when iridectomy could not be performed or when it had failed; and much more recently the operation has been advocated by Blanco,[2] Fröhlich,[3] Freeland Fergus,[4] and R. H. Elliot.[5] Major R. H. Elliot's suggestion was that after a flap of conjunctiva had been reflected from the neighbourhood of the limbus, a hole should be made with a small trephine through the sclera into the anterior chamber. The operation might or might not be combined with a small peripheral iridectomy. The underlying idea was that by these means a permanent filtering cicatrix might be established between the anterior chamber, on the one hand, and the subconjunctival space, on the other.

In the following case of acute glaucoma, referred to me by Dr. S. H. Craig, the Fergus-Elliot operation had a happy result.

The patient, aged 67 years, was first seen by me on Nov. 30th, 1909. The history was to the effect that on the night of Oct. 22nd-23rd she was seized by "biliousness," characterised by vomiting, severe headache, and by some, but not by much, pain in the eyes. On the fourth day of the illness (Oct. 26th) the sight was found to have failed seriously in both eyes. The patient was seen by Dr. Craig on the following day. Recognising the glaucomatous nature of the attack he prescribed physostigmine, which had been applied to the eyes ever since. As a child the patient's left eye had squinted, and the sight of that eye had always been defective as compared with its fellow.

When I saw the patient on Nov. 30th she looked ill, and her face bore traces of considerable suffering. The sight of the right eye, which was as hard as a stone, was reduced to perception of light. The pupil was widely dilated and motionless. The eyeball was congested in a dusky sort of way. No view of the fundus could be obtained. The eye was convergent. As regards the left eye, sight was equal to 5/60. The pupil was semi-dilated and motionless. Tension was plus 2. There was no definite redness of the eyeball. The disc was cupped, but not in a glaucomatous sense. Physostigmine, applied freely to both eyes, reduced the tension of the left eye perceptibly.

On Dec. 1st, under the influence of ether followed by chloroform, given by Dr. Craig, Elliot's operation was performed upon each eye, the upper margin of the sclero-corneal junction being selected for the trephine hole, made by means of a Bowman's corneal trephine 2 mm. in diameter. As regards the right eye, the iris presented in the hole and a piece was therefore excised. No iris was removed from the left eye. The conjunctival flaps were retained in place by sutures, physostigmine was instilled, and both eyes were bandaged. The eyes were dressed on Dec. 4th, but nothing was dropped into them. Later in the day the patient developed delusions, believing that the nurses were going to give her chloroform, and so forth. On Dec. 7th there was no pain, the eyes showed little reaction, and tension was normal. As the delusions still continued the patient was got out of bed and a double shade was substituted for the binocular bandage. These steps had the happiest result, for on the following day she was almost herself again. From this time the progress of the case was uneventful.

The patient was last seen on Jan. 20th, 1910—that is, 50 days after the operation—when her condition was as follows. Right eye: Vision 6/9 and No. 6 Jaeger. With presbyopia corrected with a +4 D. spherical lens she read words in No. 2 Jaeger. The eye was white, except where the conjunctival flap was raised. A bleb-like filtering cicatrix lay above the cornea. The pupil was oval, with the small end upwards. The edge of the iris was free from adhesions. A small coloboma, the result of the iridectomy, could be made out above the normal pupil. Left eye: Vision 6/24 and No. 6 Jaeger. With presbyopia corrected with a +4 D. spherical lens she read No. 4 Jaeger. The eye was white except as regards the place where the flap of conjunctiva was resected. A tiny prolapse of the iris was to be made out at the outer end of the wound. Tension was normal in both eyes. The fundus of each eye could be plainly seen. The optic discs were deeply cupped, but only partially so. The left eye was slightly convergent, with some tendency to an upward deviation.

NOTES ON A CASE OF INTRA-UTERINE HÆMORRHAGE WITH A NERVOUS ORIGIN.

BY D. FENTON, M.B., CH.B. EDIN., D.P.H.

THE patient, a young married woman aged 26 years, was attended by me in her first confinement. On making a vaginal examination, when called to the case about 2 A.M., I found the os sufficiently dilated to admit two fingers. I waited an hour to ascertain whether it would be worth while going home again, and on my second examination concluded, in consequence of the rapid progress of the case, that it would be highly unsafe for the patient to be left. A fine healthy male child was born about 4 A.M. without the aid of any anæsthetic or instrumental interference, but there was a small rupture of the perineum. The placenta was delivered spontaneously about ten minutes after the birth of the child, and the perineum was then repaired.

The puerperium was normal in every respect up to the end of the second week. On the morning of the fifteenth day I received an urgent summons to the patient as she was "very bad." At the time of my visit I found her blanched, with a pulse-rate of 96, normal temperature, and absolute freedom from pain. The patient's mother informed me that her daughter had had a severe flooding which had come on, without the slightest warning, that morning. Although I had examined the placenta and had satisfied myself that nothing had been left in the uterus at the time of the confinement, I carefully examined the blood clots to ascertain if by any chance there had been a succenturiate placenta, and if an "island" of placenta which had been inadvertently left behind had come away, but my examination was negative. I then examined the patient carefully for any evident cause of the hæmorrhage, but this examination also was negative.

It struck me that the hæmorrhage was of nervous origin, and, on inquiry, I learned that the previous evening the patient's brother-in-law had gone to the house in a state of intoxication, had made himself a general nuisance, and had, in consequence, very much upset her. During the night the patient, who is inclined to be somewhat superstitious, was awakened by the barking of the house-dog, and this was construed by her into a "death-warning," and she concluded that either she herself or some of her near relatives were approaching dissolution. The result was that she passed the rest of the night in a state of restless wakefulness, tossing about in the bed. I gave a favourable prognosis, ordered light diet, and prescribed a sedative mixture, with eminently satisfactory results.

It is generally admitted that diarrhœa and polyuria may be caused by nervous excitement, and Dr. G. A. Sutherland, speaking of gastrostaxis, says: "Sometimes an attack is traced to hard work, or worry, or anxiety," obviously suggesting a nervous element. Therefore I see no reason why an intra-uterine hæmorrhage, probably from the placental site, in a woman recently confined, may not also be of nervous origin, and to my mind the above case seems to bear out this contention.

Blackburn.

Medical Societies.

ROYAL SOCIETY OF MEDICINE.

CLINICAL SECTION.

Exhibition of Cases.

A MEETING of this section was held on Oct. 13th, with Sir ALFRED PEARCE GOULD in the chair.

Sir FREDERIC EVE showed a case of Myeloid Sarcoma of the Tibia in a girl aged 18, who was admitted to hospital with a large endosteal sarcoma of the head of the left tibia of six months' duration. After the diagnosis of myeloid sarcoma had been confirmed at operation, the upper third of the tibia containing the tumour was resected and the articular cartilage of the femur was removed. The fibula was exposed and about 6 inches of it were sawn off, the periosteum being carefully preserved. A hole was bored in a vertical direction in the ends of the femur and tibia respectively, and into these holes the portion of fibula was bolted in such a manner that the ends of the two bones were separated about 1¾ in., the limb being correspondingly lengthened. Primary union took place and the junction between the bones had gradually become firmer. Radiographs taken from time to time showed that the transplanted fibula had increased in circumference by new formation of subperiosteal bone, and the interval between the femur and tibia had become narrower owing to growth of bone from their periosteum and cut surfaces. Recently some interesting observations had been made by Axhausen and Lobenhoffer on the changes which take place after implantation of living bone. They showed that when bone covered with periosteum was transplanted the bone substance itself died and only the periosteum and endosteum lived. The new bone formation proceeded, therefore, mainly from the periosteum, and ultimately led to the reparation of the entire bone. In transplantation operations the periosteum must be preserved if the growth and permanent fixation of the graft were required. It was well established that myeloid sarcomata did not recur after local removal. Sir Frederic Eve had that week seen two of his cases illustrating this point. One a man, aged 35, had a large myeloid sarcoma of the fibula. It had broken through its capsule, and the microscope showed an infiltration of myeloid and round cells in the muscles surrounding the growth. The upper half of the fibula was removed with the adjoining tissues. Eight years subsequently there was no recurrence. In the second case a myeloid sarcoma of the size of a tennis ball was removed by scraping from the head of the tibia of a man, aged 22. Four and half years later the limb remained healthy. In erasing these tumours the hæmorrhage was very free and had to be guarded against by applying a tourniquet.

Dr. JAMES GALLOWAY showed a case of Severe Facial Neuralgia Associated with Myoma Cutis, and the advisability of injecting alcohol into the main branches of the left fifth nerve was discussed.

Dr. WILFRED HARRIS showed a case of Acute Encephalitis in a girl aged 13, who on May 21st was seized with a shivering attack, followed by severe headache and vomiting, with pyrexia. She became delirious and unconscious on the following evening, and did not speak again for 13 weeks. She was at first considered to be suffering from "heat apoplexy." Her recent condition pointed to the cerebellum as being particularly involved, but the past history of the case indicated a much wider area of cerebral inflammation, though the pyramidal system seem to have escaped.

Dr. H. D. ROLLESTON and Mr. W. P. TINDAL-ATKINSON showed a case of Spondylose Rhizomélique in a man aged 49. Fourteen years ago pain and restriction of movement began in his hips; pain in the spine began 11 years ago. The disease had progressed until the spine had become immoveably fixed five years ago; since then he had been subject to sudden attacks of pain beginning in the heels, extending to the neck and head, and making his bed feel like a "bag of spikes." All the bones were unduly translucent, probably from disuse.

Mr. R. C. ELMSLIE showed a case of General Thyroid Malignancy in a woman aged 61. In April, 1911, she began to feel pain in the right wrist, which was treated as rheumatism until July 1st, when a swelling appeared. At that time there were pain and swelling on the radial side of the right forearm, a short distance above the wrist. All the movements of the wrist, as well as pronation and supination, were limited. A skiagram showed an endosteal swelling of the lower part of the shaft of the radius. The swelling was thought to be a sarcoma, and in July a portion of the affected part of the radius was excised. Microscopic examination of the growth showed that it consisted of thyroid tissue, not evidently carcinomatous, but resembling rather an adenoma mostly of the fœtal type of thyroid, but some of the alveoli contained colloid. In September the patient had a severe attack of dyspnœa lasting several days and resembling severe asthma; this, she stated, had been a frequent occurrence with her in the autumn and winter. On that occasion, however, although she had improved, the dyspnœa, stridor, and hoarseness persisted. The thyroid enlargement had increased a little in the last two months, and the veins of the root of the neck on the left side had become distended. The movements of the vocal cords were at present natural.

Cases were also shown by Mr. P. LOCKHART MUMMERY, Mr. C. WARD, Dr. H. BATTY SHAW, Mr. P. S. MARTIN, and Mr. H. MORRISTON DAVIES.

The meeting concluded with a paper on an Epidemic of Acute Anterior Poliomyelitis in Cornwall, by Dr. A. GREGOR and Mr. L. B. HOPPER.

UNITED SERVICES MEDICAL SOCIETY.—A meeting of this society was held on Oct. 11th, at the Royal Army Medical College, the President, Major E. B. Waggett, R.A.M.C. (T.), being in the chair.—The President, in his opening address, said that the election of a Territorial officer to the presidency of the society was in part due to the desire felt by the council and members to emphasise the fact that the society was intended for the benefit of all the medical services, and was not confined to the Royal Army Medical Corps, an erroneous impression due to the fact that the meetings were held in the Royal Army Medical College. He hoped that his brother territorial officers and those *à la suite* officers who only undertook to do military work in time of war, would accept the fraternal offer held out to them by their brethren in the regular services of the army and navy, and would join the society in greater numbers than they had done hitherto. They would have the very great advantage of hearing military medical matters discussed by those who had had practical experience of such things in war and in peace. An instance of the necessity for such discussion occurred in the paper which was to be read that evening, and which, if he was not mistaken, would show that the recent alterations in the shape of the bullets used by the principal Powers were destined to modify very considerably the conceptions of military surgery which were formed from experiences in South Africa.—Major E. M. Pilcher, D.S.O., R.A.M.C., read a paper on "The New Bullets." He pointed out that all the alterations in the form of the bullet from the time of the old round bullet were primarily made with the object of getting better ballistic properties. Secondary aims were reduction in weight of ammunition, lessened recoil on firing, and effective wounding power. This last question had been so much put on one side that in 1892 serious complaints arose as to the inefficacy of the small-bore bullet of the time in stopping men and in putting them definitely *hors de combat*. War experience showed that the ·303 bullet gave more explosive effects when bone was touched than its predecessors, but that in soft tissues the track was usually narrow, not readily infected, and healed rapidly. Latterly many of the chief Powers had adopted bullets which agreed in being lighter and in having a sharply pointed nose. These met with less resistance when passing through air, and the following eddy was reduced. This reduction in the following eddy was accompanied by a greater tendency of the bullet to wobble, and this tendency was increased by the fact that, owing to the pointing of the nose, the centre of gravity of the bullet was thrown much further back. Experiments with bullets of this type showed that the entrance wound was always small, but that there was an explosive exit wound in 30 per cent. of cases. In two-thirds of all wounds there was evidence that the bullet had turned over in its course through the tissues. Only 17 per cent. of the wounds could be classed with the simple flesh wound typical of the ogival bullet; in the remainder the wounds were more severe, especially in the soft parts, where the track was surrounded by an area, greater or less in extent, of torn tissue. The

wounds in bone, on the other hand, were very similar to those produced by the ·303 bullet. Experiment showed that the increased severity, which was in future to be expected in wounds of the soft parts, was due chiefly to the great tendency shown by the newer patterns of bullets to turn over on meeting with any resistance. As to the degree of increased severity of the wounds, the lecturer thought that one might expect a return to the conditions present in the days of the Snider bullet, with, at short ranges, an added increase due to the much greater velocity of the new bullets. — Lieutenant-Colonel J. B. Wilson, R.A.M.C., Fleet-Surgeon W. E. Home, R.N., Major H. A. Bray, R.A.M.C., and the President took part in the discussion.

SOCIETY OF MEDICAL OFFICERS OF HEALTH.—The annual meeting of this society was held on Oct. 13th, when Professor A. Bostock Hill was formally introduced as the President for the ensuing session by the retiring President, Dr. W. G. Willoughby.—In his presidential address, which dealt with the Evolution of the Medical Officer of Health, Dr. Hill said that it was difficult to conceive a period of civilisation when there was no elementary sanitary service. Probably the earliest real sanitary work was that undertaken for the prevention of floods; and when men began to collect into communities it became necessary to arrange for the removal of waste products which hindered access to their dwellings and reduced the comfort of existence. The earliest records of a preventive service were those of Rome, where officers, termed ædiles, were appointed who were established as *curatores urbi* in 495 B.C. The medical service of Rome undoubtedly included a Poor-law service. The officers not only had to attend the poor, but they were allowed to take fees from the rich so long as the legitimate Poor-law work was not interfered with. From the point of view of civilisation and of municipal government probably no greater disaster befell the world than the fall of Rome. Then much of the carefully elaborated municipal work perished and succeeding generations had slowly to endeavour to reconstruct a system of public health administration. After referrring to spasmodic efforts to enforce sanitary measures in the City of London which were made by Edward III., Henry VIII., and Queen Elizabeth, Dr. Hill said that the nineteenth century must ever be memorable as that in which modern hygiene was born and in which the medical sanitary officer came into existence. In the first decades of the last century the most important sanitary work accomplished was the passing of the Registration Acts. This enabled the statistician for the first time to collect statistics in a scientific form on which could afterwards be based the present administrative system of public health. The Public Health Act of 1848 was the result of the report of the Royal Commission on the Health of Towns. It did not, however, provide for the appointment of medical officers of health. During the next 20 years the main work in the evolution of the medical officer of health was educational. Facts accumulated, based on statistics and the progress of medical science, and the Public Health Act of 1872 permitted the appointment of medical officers of health, while the Act of 1875 made those appointments compulsory. In the early days their chief work was the advising of the removal of those great nuisances which had been shown to be hostile to a reasonable degree of public health. In many of the minor districts the appointments were made by councils which did not understand the necessity of public health work. In a large number of instances the officers were discouraged from doing more than was absolutely necessary. One of the most important points in connexion with the work of a medical officer of health at the present day was the education of the public as to what was the meaning of modern hygiene, and this could only be done by a medical man who was a specialist, and therefore a medical officer of health.

MEDICO-CHIRURGICAL SOCIETY OF GLASGOW.——A meeting of this society was held on Oct. 6th, Dr. A. Freeland Fergus, the President, being in the chair. Dr. Fergus opened the new session by delivering a presidential address on the Rise and Progress of the Glasgow School of Medicine: from Maister Peter Lowe to Sir William T. Gairdner. After speaking of the early workers in medicine in Glasgow he pointed out that many men of the first rank in medical science, who had attained their distinction for the most part in the south country, were connected with the west of Scotland, and he instanced as Lanarkshire men William Hunter, John Hunter, Matthew Baillie, and Smellie. He pointed out that the medical school of Glasgow in great part owed its origin to the influence and work of Cullen, who was perhaps the first to give systematic instruction in medicine in Glasgow. An interesting line of succession was pointed out in so far as Cullen taught Joseph Black, Black taught Thomas Thomson, Thomas Thomson taught Graham, afterwards master of the Mint and professor of chemistry at University College, and Graham taught Joseph Lister. All these men were connected with Glasgow, and the name of each is to be found on the list of the Royal Faculty of Physicians and Surgeons. It was during his term of office in Glasgow that Lister revolutionised surgery, and practically introduced to the world the modern biological pathology which has not only been useful in surgery, but has also markedly influenced work in the departments of public health and medicine. The Glasgow Royal Infirmary was the institution in which modern surgery was actually called into being. The influence of Sir William Tennant Gairdner, Dr. Fergus said, had been of the greatest importance. He characterised him as a man of great simplicity of character, of profound and wide scholarship. If it were important to young students to be brought into contact with a man who invariably took a philosophic view of a subject, who was profoundly learned in the matters under discussion, and who was most painstaking about the minutest details, then Gairdner was without comparison the best teacher of his time. Fortunately for the city of Glasgow, Gairdner was not only professor but was for a time also medical officer of health, being the first to hold that appointment. The Public Health Department of Glasgow was practically organised by him, and was carried on after his retirement with conspicuous ability by Dr. J. B. Russell. Amongst other Glasgow practitioners and professors the lecturer mentioned Dr. Andrew Buchanan, who was the first to give any succinct account of the phenomena of the coagulation of the blood; Allen Thomson, who was one of the earliest workers in the domain of microscopic embryology; William MacKenzie, who in his day was one of the leading ophthalmic surgeons of the world; and Robert Perry, who while a physician in the fever wards of the Glasgow Infirmary clearly differentiated between typhus and enteric fevers.

BRIGHTON AND SUSSEX MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on Oct. 5th, Mr. H. H. Taylor, Vice-President, being in the chair.—Mr. A. G. Bate showed a man with Severe Spasmodic Torticollis, in whom palliative measures having been tried with no success the spinal accessory nerve was resected for about an inch, but the result was almost *nil*. The posterior divisions of the upper cervical nerves were then divided, and as two years had now passed and a complete cure of the spasms had been obtained Mr. Bate thought he was justified in hoping that the result was permanent.—Mr. Bate also showed a case of Tabes with Gastric Crises of 11 Years' Standing Treated by Förster's Operation. Laminectomy of the fifth to the eighth dorsal vertebræ was first performed, the dura was opened, and the posterior divisions of the seventh to the tenth dorsal nerves were divided. Three months had now passed and the gastric crises had quite disappeared.—Dr. W. Broadbent showed a case of Hypertrophic Pulmonary Osteo-arthropathy. The man had well-marked enlargement of the lower ends of the forearms and wrists, clubbing of the fingers, swelling above and around the knee-joints, which contained fluid, and enlargement of the ankles. He had had a cough from boyhood. The sputum was fœtid. There was dulness over the lower lobe of the left lung with distinct cavernous signs. The heart was pulled over till the apex was in the left axillary line. No tubercle bacilli were found. Probably there was an old empyema which had ruptured into a bronchus.—Dr. E. Weatherhead showed a specimen, removed post mortem, of a fœtus which had been retained in utero for 40 years. The patient had been shown at the society 39 years ago with a large abdominal tumour. One member then thought it was a fœtus encysted in the abdominal cavity, probably with a fibroid tumour of the uterus, but no other member agreed with this diagnosis, most of them regarding the swelling as a fibroid. At the necropsy, made nearly 40 years later, the tumour was found to consist of the fœtus lying in a bag of membranes, more or less completely calcified. It lay in the

breech position. All the parts were easily distinguishable. The substance of the fœtus had a curious waxy consistency, suggesting that it might be partly converted into adipocere. It had probably reached about the eighth month and weighed about 4 lb. The record cases of long retention of a fœtus reported in the Transactions of the Obstetrical Society were one by Cheston of a lithopædion, which had remained for 52 years, and another by Barnes of 42 years' standing.—Dr. F. W. Price read a paper on Newer Conceptions of Cardiac Disease.

BATH CLINICAL SOCIETY.—A meeting of this society was held on Oct. 6th, Dr. Preston King, the President, being in the chair.—Among the cases and specimens shown were: A man, aged 39, with Double Inguinal and Double Femoral Herniæ, and a child, aged 2, with Cavernous Sinus Thrombosis following an injury 14 days previously, by Dr. A. J. Bruce Leckie; a child, aged 11, with a loud Systolic Murmur heard all over the præcordial region, most marked over the pulmonary area, who otherwise showed no signs of congenital heart disease, by Dr. G. H.-H. Almond; bismuth X ray photographs, showing Gastroptosis before and after operation, and cases of Rodent Ulcer treated by zinc ionisation, by Dr. G. E. Bowker; a Thymus weighing 22½ grammes removed from a girl, aged 23, who died under chloroform during an operation for the removal of a nasal polyp, other signs of acute lymphatism being enlargement of the superior mediastinal glands and some enlargement of the spleen, by Dr. F. G. Thomson.

HARVEIAN SOCIETY OF LONDON.—This society held a clinical evening at St. Mary's Hospital on Oct. 12th, Mr. J. Ernest Lane, the President, being in the chair.—The following members showed cases: Sir John Broadbent, Bart.: Jaundice.—Captain S. R. Douglas, I.M.S., and Dr. Graham Little: Gonococcal Keratodermia Blennorrhagica.—Dr. W. H. Willcox: (1) Abdominal Tumour in a child; (2) Syphilitic Intracranial Tumour; and (3) Aortic Regurgitation.—Mr. D. C. L. Fitzwilliams: (1) Skiagrams of Renal Lithiasis; and (2) Ulcerated Non-malignant Tumour of the Tongue.—Mr. C. W. M. Hope (for Dr. William Hill): Two cases of Stricture of Œsophagus.—Dr. Graham Little: Artificial Dermatitis.—Mr. V. Z. Cope: Actinomycotic Abscess of the Cheek.—The cases were discussed by various members.

Reviews and Notices of Books.

England's Recent Progress. By THOS. A. WELTON, F.S.S., F.C.A. London: Chapman and Hall. 1911. Pp. lxiv.–742. Price 10*s.* 6*d.* net.

IN this interesting treatise Mr. Welton gives an account of his investigations respecting the movement of the English population in the course of the 20 years 1881–1901, and contrasts the first ten years with the second. The objects the author had in view when projecting this work may be briefly stated as follows: 1. To study the progress, or want of progress, of different communities, as indicated by the balance of migration in two consecutive decennial periods. 2. To consider the relative mortality in these communities at several stages of life; the effect thereon of migration; the various disturbing influences; and the extent to which local mortality has been reduced in recent years. Mr. Welton is by no means a novice in researches of this kind, as witness, among other things, his instructive essay on the growth and distribution of the population in the 90 years 1801–91.[1]

Whatever tends to the instruction of the public respecting sanitation is deserving of encouragement, as a matter of national concern. Mr. Welton's book must be welcomed as likely to promote such instruction. Based, as it is, on researches extending over two decennia, it should prove valuable as a means of gauging the amount of migration in individual populations as well as of accurately measuring their mortality. In the process of investigating local movements of population much light is incidentally thrown on questions of comparative mortality, as well as of birth and marriage ratios, all of which powerfully affect the growth of populations. In the text an account is given of the places that attract the largest numbers of immigrants, specifying those showing the greatest changes in the second decennium as compared with the first. Believing that accretions of inhabitants at ages from 15 to 40 give a better notion of the progress of a place than could be derived from study of the total movement of the population, the author limits his remarks mainly to this period of life. The movement of population at ages below 15 forms the subject of a separate chapter; it is influenced largely by the attraction of residential places for those leaving home in quest of education or of health. At ages exceeding 40 years the movement is almost confined to large towns and residential places where immigrants at this age are economically important as employers of labour.

In this country the migrations of the sexes are so dissimilar as to require separate treatment. The well-known tendency towards round numbers, which vitiates many returns, has been allowed for in the present work; as also has the tendency to misstatement of age by women who, between the ages of 25 and 40, are not unnaturally prone to understate their years. On the other hand, working-class boys as well as girls add something to their ages in order the sooner to attain the wages of adults. Moreover, old men as well as old women reaching 65 years frequently exaggerate their ages. Since 1851 the inhabitants of English towns have acquired the habit of distributing themselves over wider areas than previously. Accordingly, Mr. Welton has endeavoured so to group the parishes as to give every place an ample boundary. This is the more necessary because of the prevailing tendency for whole families to migrate from the centre to the circumference of a great city; one result of which is that the statistics of the whole area cannot be regarded as complete unless the parishes receiving such migratory families fall within the boundary chosen. It is found that the districts on the fringe of a large town are affected, not only by the usual loss of population resulting from the inability of our rural areas to retain their native-born, but by the influx of families coming from the town centre.

In the two decennial periods under notice a marked stability exists in the conditions generally prevailing. At ages 15–25 there has occurred universally a loss of rural population which affects the numbers who, at the end of a decennium, are aged 15–35. In the chief colliery districts there are gains of youths and of women somewhat older—boys, in fact, for the pits, and brides for the older men. But the high birth-rates there influence the growth of population more powerfully than do the migrations. Some of the industrial districts are adjacent to collieries and show very similar peculiarities. In cotton and woollen districts there is a tendency to lose male inhabitants and to attract females. The local birth-rates are specially low. Residential districts, for the most part, lose young men; all of them attract young women and persons of both sexes after 35. Old towns generally lose young men, and women a little older tend to leave them. These places commonly show moderate gains of both sexes after the age of 50.

In discussing the statistical methods adopted for ascertaining the tendency towards marriage in particular localities, the author dismisses as without value the simple ratio of marriages to population because of the extreme variability of the proportion of unmarried men at ages 20–35 to population at all ages. The proportion of unmarried young women also varies considerably, and so little do the statistics for the

[1] Statistical Journal, 1900, pp. 527–589.

sexes correspond that even within the limits of the County of London alone the ratio of unmarried women to unmarried men at 20–35 is sometimes as low as 60 per cent. and at others as high as 249 per cent. The author regards the proportion of men found to be in the married state at the age 45–55 as a fair measure of the general tendency to marry. The national figures indicate some falling off in the proportion of persons married, while the proportion of the unmarried seems to have increased in the last vicennium by about one-twelfth. From the figures adduced there appears to be a stronger tendency to marry in the eastern and western counties than in the busy counties of the north, whilst in the rural parts of the north of England there is also a comparative indisposition to marry. With reference to the depressed birth-rate, the author remarks that, inasmuch as the proportion of married women at ages under 45 varies considerably in the several districts, it is unsafe to compare the births with the total female population, or even with the number of married women aged 20–45. The better course seems to be that recently adopted by the Registrar-General, which consists of comparing births with the married women living under 45 years of age. Mr. Welton's figures give support to the official statement that since 1881 there has been everywhere a progressive decline in the birth-rate, particularly in the textile manufacturing places and in the residential towns.

In a work like the present statistics of mortality naturally bulk somewhat largely. From the data here presented we learn that during the prime of life the rural death-rates are considerably modified by the migration of healthy young men to towns in quest of higher wages. After years of town dwelling many of these *quondam* rustics return to their country homes seriously damaged in health by their encounter with urban conditions of life. As an instrument of comparison, Mr. Welton has devised a "scale of mortality for healthy places," which approximately fits the case of the best rural districts as existing in 1881–90, and which represents the percentage loss by death in that decennium. In the several tables appended, these rates are taken as 100, and the actually recorded rates are shown as more or less than this, according to circumstances. In justification of the use of this standard, it is contended that the rates of mortality thus indicated are not materially below a level which is easily attainable in a healthy rural district. In a series of tables the national average loss of life is worked out for each of the specified decennial periods. In the first 15 years after birth there appears to have been no change as between the first period and the second. At later ages a considerable reduction of mortality is recorded. The figures show that the scale of death-rates at ages 25 to 40, arrived at on the basis of the experiences of the earlier decennium, as representing *female mortality* in healthy districts, exceeds in the later decennium the average mortality in all districts whether healthy or otherwise. This is a surprising improvement. On the other hand, the figures indicate a relative aggravation of *male mortality* between the ages of 20–25 and 40–45, proving that unhealthy conditions affect the male sex most severely. The textile and other manufacturing towns and the colliery districts experience heavy loss of infant life. This has been aggravated in the last-named districts, and up to the close of last century had not been greatly reduced anywhere else, except in the rural parts of the South and East of England. Since 1901, however, much improvement has taken place, especially in the colliery districts.

In this connexion attention must be directed to two important sets of graphs which appear in the preface of this book—one set relating to migration at several ages, the other to the percentage losses experienced by successive generations in either of the decennial periods ended respectively with 1890 and 1900. The labour involved in the calculation of the curves necessary for the graphs—140 in number—must have been enormous. The whole work bears eloquent testimony to the energy and public spirit of the author. Considerations of space forbid the attempt even to summarise the teaching deducible from these graphs and their accompanying tables, for which reference must be made to the book itself.

After a careful perusal of this work the reader must be impressed, as we have been, with the abundance and variety of instruction it contains on subjects which are not readily accessible, and which will be found invaluable to students of vital statistics. In its present compendious form we believe that nothing of the kind has previously been published in a single volume. The book deserves a wide circulation.

A Handbook of Practical Treatment. By Many Writers. Edited by JOHN H. MUSSER, M.D., LL.D., Professor of Clinical Medicine in the University of Pennsylvania, Philadelphia; and A. O. J. KELLY, A.M., M.D., Assistant Professor of Medicine in the University of Pennsylvania. Volume I. London and Philadelphia: W. B. Saunders Company. 1911. Pp. 909. Price £3 15*s.* net the set (three volumes).

THIS important work is a systematic treatise on treatment, regarded as an art based upon scientific principles. While its object is essentially practical, the presentation of the evidence upon which the various recommendations are made is by no means neglected. As a consequence, it will extend to three large volumes. The editors have arranged their subjects conveniently and chosen their collaborators with discrimination, since the individual articles are generally of a high order. In the first volume for the most part general methods of treatment are reviewed, and questions of mechanical, electrical, climatic, and other special forms of treatment are considered.

Dr. J. H. Musser, the senior editor, contributes an introductory article on the fundamental principles of therapeutics, in which the expressions of disease and the methods of treating them are discussed. The subject of preventive treatment is dealt with in an article by Dr. C. H. Harrington, which has been revised by Dr. A. C. Abbott. In connexion with Governmental prophylaxis, the public health services of England, France, Germany, and the United States are described. Individual prophylaxis, protective inoculation, and disinfection are successively dealt with. A thoughtful and rational analysis of the general principles of dietetics is contributed by Dr. David L. Edsall, who discusses the questions of protein, carbohydrate, and fat intake, and arrives at rational and moderate conclusions, which would probably be acceptable to all except dietetic faddists and extremists. Dr. Maynard Ladd treats of the dietetics of infancy. He gives useful and full instructions in regard to breast-feeding, and describes in detail the percentage modification of cow's milk which is so strongly recommended by American pædiatrists. He gives a useful table of instructions for the carrying out of this method, which, in spite of its explicit nature, is still somewhat complicated for ordinary use.

Sir Lauder Brunton writes on the general principles of drug treatment, and reviews the main lines of treatment of the different systems of the body. Dr. Ludwig Hektoen, in an interesting article on the general principles of serum-therapy, outlines the cardinal facts known in regard to immunity, and describes the chief specific forms of treatment of infective disease. He includes vaccine treatment within this survey. Dr. Warren Coleman deals with the general principles of organotherapy, and indicates the chief practical applications of this form of treatment. Dr. Charles W. Burr contributes an article entitled "The Rest Cure, the Work Cure

and Psychotherapy," and Dr. R. Tait McKenzie, a comprehensive and instructive study of exercise, massage, and mechanotherapy. This last article is abundantly illustrated and contains some useful schemes for the application of these forms of treatment to various deformities, diseases of the circulatory system, and nutritional and nervous disorders, rendering it one of the most valuable parts of the book. Dr. Guy Hinsdale writes on hydrotherapy and balneotherapy, and Dr. Henry Sewall on climatotherapy and health resorts and on artificial aerotherapy. Electrotherapy is described by Dr. J. Montgomery Mosher, and radiotherapy by Dr. Henry K. Pancoast. The therapeutic applications of the X rays and of radium are discussed, but less attention is given to their use in malignant disease than we should have expected.

Under the heading of miscellaneous therapeutic measures Dr. George P. Müller describes the technique and uses of procedures such as venesection, leeching, passive hyperæmia by Bier's method, various forms of puncture and paracentesis, saline irrigations and infusions, and gastric lavage. This article is a specially practical and helpful one. Dr. M. Howard Fussell deals with the general care and management of the sick and the treatment of slight ailments, Dr. George Blumer with food intoxication and poisoning by reptiles and insects, and Dr. Horatio C. Wood, jun., with drug poisonings and drug habits. Dr. James Tyson contributes a short article on the treatment of sunstroke.

The remainder of the book contains an account of the treatment of diseases of the blood and of the lymphatic system and the ductless glands, the former by Dr. Richard C. Cabot, the latter by Dr. George Dock. The directions given for the management and treatment of some of the obscure and intractable conditions included under these headings are explicit and practical. A short article on the surgical treatment of diseases of the thyroid and parathyroid glands, by Dr. J. C. Bloodgood, gives a description of the operative procedures now employed in the treatment of exophthalmic goitre, and also contains reference to the parathyroid glands and their relation to tetany in connexion with operations on the thyroid gland.

Principles of Anatomy: The Abdomen Proper Described and Illustrated by Text and Plates. By WILLIAM CUTHBERT MORTON, M.A., M.D. Edin. London: Rebman, Limited. 1911. 174 pages of text, illustrated by 19 figures; and 14 plates, with special frame for same. Price complete, 42*s.* net.

THE work consists of 14 outline drawings of the abdomen, constructed in such a manner that the outlines all coincide, and when held up to the light in the special frame provided, may be superimposed and viewed as transparencies for the study of the relations of organs at different levels within the abdomen. The idea is an ingenious one, for different combinations may be made of the plates, so that various organs may be studied in their relation to each other and to the surface of the body. The text is noteworthy for the strange variety of type employed, some of the pages being irresistibly suggestive of Snellen's test types. Of the purpose of the work the author says: "It is intended not to rival, but to stimulate, practical study, to be used before dissection for a preliminary survey, during dissection for comparison and contrast, after dissection for revision, and at all times for reference." It is obvious that it cannot take the place of any of the three essentials of anatomical study—the dissecting-room subject, the dissecting-room manual, and the text-book of anatomy, though it might be a useful supplement. The author has reverted to the fashion of a former generation of anatomists in introducing his work by means of a poem of apology. The fashion was by no means a bad one, and the author owes a debt to John Bunyan, from whose "Apology" for the Pilgrim's Progress he has culled his lines. One is tempted to wish that he had quoted more fully from the Apology of the "wonderful tinker," and added the lines—

> "If that thou wilt not read, let it alone;
> Some love the meat, some love to pick the bone."

Nouveau Traité de Chirurgie. (*New Treatise on Surgery.*) Publié sous la direction de A. LE DENTU, Professeur Honoraire de Clinique Chirurgicale à la Faculté de Médecine, et PIERRE DELBET, Professeur de Clinique Chirurgicale à la Faculté de Médecine. *Affections Chirurgicales de la Poitrine.* (*The Surgery of the Chest.*) Par CHARLES SOULIGOUX, Chirurgien des Hôpitaux. Avec 48 figures. Paris: J. B. Baillière et Fils. 1911. Pp. 282. Price, paper, 6 francs; bound, 7.50 francs.

WITHIN the last few years the surgery of the chest has made great progress, and the space devoted to this subject in treatises on surgery is very much greater than it was even a decade ago. While progress has been made in many parts of thoracic surgery, it has been especially great in the surgery of the heart and of the mediastinum. In this volume we find these portions of the subject more fully dealt with. Most of the various incisions for operation on the heart are described. The author prefers the method of Delorme and Mignon. The surgery of the lung is adequately presented for a general treatise on surgery, and we are glad to see that the methods of Sauerbruch and others, which permit the pleuræ to be opened without interfering with the expansion of the lungs, are given; but the author does not express any very definite opinion on the relative value of these methods. This section is worthy to form part of the "Nouveau Traité de Chirurgie."

An Introduction to Therapeutic Inoculation. By D. W. CARMALT-JONES, M.A., M.D. Oxon., M.R.C.P. Lond., Assistant Physician and Director of the Department of Bacterio-Therapeutics, Westminster Hospital. London: Macmillan and Co. 1911. Pp. 171. Price 3*s.* 6*d.* net.

THERAPEUTIC inoculation, or vaccine-therapy, has already become established as an important means of treating many infections, and is certainly one of the most striking practical results of the study of bacteriology. Although comparatively simple in practice, it is based upon the highly complex phenomena of immunity, and its rational application demands at least a general knowledge of the mechanisms of infection and of the protective reactions of the body in response to bacterial invasion. It should be clearly recognised that the method is still in the experimental stage and that the empirical or haphazard use of vaccines is liable to lead to disappointment and to bring discredit upon a useful method of treatment. Vaccine-therapy should, as a rule, be employed only in cases in which a definite bacteriological diagnosis has been established.

Dr. Carmalt-Jones, in the book before us, has supplied a useful and practical exposition of the principles upon which therapeutic inoculation is founded, together with a review of the methods of inoculation and their results. The book is divided into two parts, of which the first deals with principles. The process of spontaneous recovery from bacterial infections is discussed, and the nature of the various antibodies is explained in simple terms. The artificial stimulation of the natural powers of recovery by means of vaccines is then described and illustrated by examples and by charts. The importance of bacteriological diagnosis is insisted upon, and the methods in use for this purpose are considered, as well as the preparation of vaccines, their sterilisation and standardisation. The difficult question of dosage is dealt with. The general nature of the results obtained and the possible causes of failure are next reviewed. The first part concludes with a brief account of

the history of therapeutic inoculation and a critical discussion of the opsonic index and its value.

The second part deals with the practice of therapeutic inoculation. Various hints are given in regard to the method of administering vaccines, and an analysis is presented of the results of treatment by this method in a variety of different conditions. The cases reviewed have either been seen by Dr. Carmalt-Jones personally or have been treated under conditions with which he is familiar, or are cases about which he has been able to obtain first-hand information. In connexion with each group of cases the minimum and maximum doses are given, and the duration of treatment and the question of relapse are also considered. Dr. Carmalt-Jones states the results dispassionately, and makes no exaggerated claims in regard to the efficacy of this form of treatment. The doses given are in many cases smaller than are used by some vaccine-therapists, and the treatment has been prolonged in not a few of the cases included in the analysis.

Dr. Carmalt-Jones's book deals in a simple, practical, and intelligent fashion with a difficult subject, and in virtue of its convenient size and freedom from technicalities it should serve a useful purpose by enabling the practitioner to apply vaccine treatment upon sound and rational lines.

A Pocket Atlas and Text-book of the Fundus Oculi, with Note and Drawing Book. Text by G. LINDSAY JOHNSON, M.A., M.D. Cantab., F.R.C.S. Eng., with Drawings from Life by ARTHUR W. HEAD, F.Z.S. With 54 figures. London: Adlard and Son. 1911. Pp. 205. Price 10*s.* 6*d.* net.

THIS book is well worth buying for the 27 excellent plates which it contains, the selection of subjects being very good. The actual drawings have been made by one of the foremost ophthalmoscopic artists of the day, and have been reproduced by the three-colour process under the supervision of Dr. G. Lindsay Johnson, who is well known as a highly expert photographer. We think that the student would hardly suffer serious loss if the atlas were enlarged at the expense of the letter-press. The latter has two faults—it is too scanty to replace efficiently the ordinary text-book, and it contains many views and suggestions personal to Dr. Lindsay Johnson and not yet generally accepted, which, though they are of considerable interest to the mature ophthalmologist, are wholly unsuitable for the student. The ophthalmic note and drawing book, which forms a detachable appendix, adds to the unwieldiness of the volume as a "pocket" atlas. Students may be urged to draw what they see, but those who have sufficient artistic skill are few.

Twice the number of plates, all equally well reproduced, shorn of the letter-press and drawing-book, would form an invaluable atlas, quite portable as a pocket companion; it might become an indispensable accessory to the text-book of ophthalmology.

The Emergencies of General Practice. By PERCY SARGENT, M.B., B.C. Cantab., F.R.C.S. Eng., Surgeon to Out-patients, St. Thomas's Hospital; Surgeon to the National Hospital for the Paralysed and Epileptic, Queen-square; and ALFRED E. RUSSELL, M.D., B.S. Lond., F.R.C.P. Lond., Physician to Out-patients, St. Thomas's Hospital. Second edition. London: Henry Frowde and Hodder and Stoughton. 1911. Pp. 454. Price 15*s.* net.

THE general practitioner frequently encounters emergencies. In large towns he can easily call in assistance, perhaps of the sort specially equipped to help him, but in the country, and especially in the more remote parts, he is often compelled to act without the benefit of the advice or assistance of anyone more experienced than himself. For men in these circumstances this book has been written, though it will also prove useful to many dwelling in towns who for great emergencies have to depend on themselves. There will very naturally be a difference of opinion as to the subjects which should be included in a work like this, and the only criticism we would offer on this point is that it was hardly advisable to include a description of wiring the patella. The risks attending opening the joint by those not specially practised in such operations are vastly greater than the benefit to be derived from an immediate suture. In this edition the authors have made many alterations, and some chapters have been re-written. A chapter on the emergencies of insanity, written by Dr. Percy Smith, has been added. This is often a very difficult subject for those in general practice, and the addition of this chapter is of special value. This second edition should achieve the marked success of its predecessor.

Handbuch der Vergleichenden Physiologie. Herausgegeben von HANS WINTERSTEIN. 15 Lieferung. Band I.: Physiologie der Körpersäfte. Bogen 1–10. Jena: Gustav Fischer. 1911. Pp. 160. Price M.5.

THE name of Bottazzi of Naples is already well known in relation to chemical physiology, and his selection as the author of the monograph "On Cytoplasm and the Juices of the Body" is a guarantee of the careful execution of the work. A very full account is given of the distribution of water and of the part it plays in vertebrate, invertebrate, and in vegetal forms of life, and the theme of no life without water is the problem discussed through many pages. There is a large number of tables, and the distribution of the chemical elements present in the body is similarly treated. The chemical composition of the constituents of cells is discussed, and while doing so the constitution, distribution, and uses of proteins, fats, and carbohydrates are set forth, particular attention being given to lipoids and their biological importance. Next the physico-chemical properties of cytoplasm are dealt with, and full consideration is given to the colloidal constitution of protoplasm. The nomenclature of Graham—sol and gel and their derivates—is introduced, while an elaborate account is given of such subjects as solutions, suspensions, emulsions, adsorption, electrolytes, imbibition, precipitation and coagulation of proteins, osmotic pressure, viscosity, and artificial and normal colloidal solutions. The study of colloids naturally leads on to the "ultra-microscope," its use, and how it has extended our knowledge of the visible constitution of so-called liquids. This "Heft," or part, breaks off at the beginning of a chapter on Definition of Colloidal Systems. Briefly, protoplasm is considered fully in its chemical and physical aspects, but the details are so numerous and technical that we can but mention the chief subjects discussed and commend Dr. Bottazzi's effort to all biologists, using that term in its widest sense.

LIBRARY TABLE.

The Life-history, Function, and Inflammation of the Appendix. An Address delivered to the Clinical Society of Manchester, January, 1911. By EDRED M. CORNER, M.A., M.C. Cantab, F.R.C.S. Eng., Surgeon to the Surgical Isolation Wards and Out-patients, St. Thomas's Hospital; Surgeon to In-patients, Children's Hospital, Great Ormond-street, &c. London: John Bale, Sons, and Danielsson, Limited. 1911. Pp. 23. Price 1*s.*—Mr. Corner gives reasons for the large number of micro-organisms in the cæcal region, and he expresses the opinion that the appendix is a storehouse of lymphoid tissue placed where it is in order to combat the micro-organisms of the cæcum. Several very striking histories are related to show that it is not at all rare to find cases of appendicitis in which no clinical evidence of any disease has been

present, and yet at the operation the presence of old inflammation and old adhesions has shown that many previous attacks of appendicitis must have occurred. Mr. Corner holds that carcinoma of the appendix is not at all rare, and that it is being found with increasing frequency when the diagnosis is made, not by the naked eye, but by the microscope. The book gives a very readable account of some of the aspects of appendicitis.

Technique de Stérilisation. Par le Dr. ERN. GÉRARD, Professeur de Pharmacie et de Pharmacologie à la Faculté de Médecine et de Pharmacie de Lille. Deuxième édition, augmentée avec 72 figures dans le texte. Paris: Vigot Frères. 1911. Pp. 352. Price 6 francs.—During the four years which have elapsed since the first issue of this book the methods of sterilisation as employed in medicine and pharmacy have increased in number, and this second edition therefore contains much more than its predecessor. The methods of sterilising instruments and dressings, the sterilisation of water, of pharmaceutical preparations, and of ligatures are described, and the methods of testing the results are also given. The sterilisation of milk has a long chapter to itself, and the disinfection of contaminated rooms is also described. Lastly, the author gives an account of the sterilisation of drinking water by means of the ultra-violet rays. The book is convenient and complete.

The Educational Treatment of Stammering Children. By T. J. T. MCHATTIE, M.D. Edin. Issued by the Medical Officers of Schools Association. London: J. and A. Churchill. 1911. Pp. 18. Price 1*s.* net.—The author considers that the cause of stammering lies in a generalised weakness in the nerve mechanism of speech, not attended in most cases by any gross physical defect. He would combat the condition in two ways: by indirectly affecting the higher centres through the muscles of respiration and speech, and by suggestive therapeutics. By the latter he does not mean hypnotism, but the getting the patient to realise that his speech organs are in perfect condition, and that there is no reason why he should not talk like other people. Enlarged tonsils and adenoids are often present, and should be removed. A report follows of the discussion on this paper when read at the association's meeting. Dr. Hulbert advocated taking the various component parts of the mechanism of speech separately, teaching them individually, and then coördinating them. Mr. Cortlandt Macmahon would, before everything else, make the patient practise "whole lung breathing," particular attention being paid to inferior lateral costal breathing; then the various vowel and consonant sounds should be taught separately and in combination. Dr. C. E. Shelly, who presided, referred to the greater incidence of stammering in boys than in girls, and suggested that in the early ages, when men were engaged in hunting, speaking was for them a disadvantage, while women at home had little else to do. He considered speech traits in the female were more stable and less easily perturbed.

An Oberland Chalet. By EDITH ELINER WOOD. London: T. Werner Laurie. 1911. Pp. 285. Price 16*s.* net.—There are some people who can attune themselves to the emotional conditions of others in whose company they are or whose words they are reading. They can thus get much enjoyment out of life, as it were, by proxy. Any such who have the *Wanderlust* will probably enjoy this record of a summer spent in Switzerland by two American ladies and the children of one of them, with later her brother and a college class-mate from Cornell. The book is breezily written, not without humour, and with glimpses of a sane philosophy. "After all, the simple life is not hard to live if you get the right setting for it," explains much that is puzzling in life; for incongruity, an appreciation of which, when others are its victims, is a great source of humour, often becomes a weariness when it affects ourselves. Save for two little trips over Latin expressions, which are as inaccurate as their introduction was unnecessary, we have enjoyed an agreeable Swiss excursion with a clever and sensible woman. There are 12 admirable pictures.

Reports and Analytical Records FROM THE LANCET LABORATORY.

MERGENTHEIM TABLETS.

(A. SIEBERT AND CO., 6, FANN-STREET, ALDERSGATE, LONDON, E.C.)

THESE tablets are convenient for use, presenting the therapeutic properties of the Karl spring at Bad Mergentheim, South Germany. Some evidence that the salts are derived from the spring itself and are not artificial is seen in the fact that, according to our analysis, the important salts present occur in the same ratio in the tablet as is in the natural water. We found that one tablet weighing just 2 grammes contained 0·219 gramme magnesium sulphate, 0·322 gramme sodium sulphate, and 1·26 grammes sodium chloride. The sodium chloride present serves to render the bitterness of the sulphates less marked.

(1) HEGONON; (2) ARTHIGON; (3) ATOPHAN; AND (4) HORMONAL.

(A. AND M. ZIMMERMANN, 3, LLOYD'S-AVENUE, LONDON, E.C.)

1. Hegonon is an elegant organic silver compound prepared by the action of ammonia silver nitrate solution on albumose. It is reported to have a remarkably favourable action in the treatment of urinary diseases, and particularly in gonorrhœa. Hegonon is easily soluble in water and shows an alkaline reaction. The solution does not coagulate albumin and is stable with salt solution. The amount of silver in this albuminous metallic compound is 7 per cent. 2. Arthigon is a gonococcus vaccine representing an aqueous emulsion of dead gonococci. It is regarded as an active immuniser on the gonorrhœic process. It is reported to have given excellent results in German clinical practice. 3. Atophan is said to facilitate the elimination of uric acid from the organism. It is a chemical compound containing two parts of phenylchinolin and four of carbolic acid. 4. The preparation of hormonal is based upon the view that normal intestinal peristalsis is caused by a specific cell product which appears to be chiefly stored in the spleen. To this cell product the name hormonal has been given. It is injected in equal quantities in the right and left gluteal muscles. In a few seconds a strong peristaltic wave is produced resulting in evacuation. A single injection is said to have a lasting effect.

KACEPE BALSAM.

(REITMEYER AND CO., 63, CRUTCHED FRIARS, LONDON, E.C.)

This balsam appears to be an advance on better-known preparations which have generally as their active constituent oil of winter-green. The active principle is the menthol ester of acetyl salicylic acid, in combination with the same salicylic group and ethyl ester, and lanoline ointment is used as a basis. It has been employed to relieve pain in rheumatism, gout, and sciatica.

(1) MALT EXTRACT; AND (2) MALT EXTRACT WITH COD-LIVER OIL.

(JAMES CALDER AND CO., LTD., BO'NESS DISTILLERY, BO'NESS, N.B.)

1. The malt extract showed an excellent degree of concentration, the total malt extractives amounting to 83·33 per cent. Its digestive power on starch according to our experiments is marked, the extract converting double its weight of starch in an hour at body temperature. At higher temperatures the digestivity increased considerably. The mineral matter amounted to 1·29 per cent. and contained a normal amount of phosphates. The flavour was excellent, showing that care is taken in concentrating the extract. 2. The malt extract

and cod-liver oil proved to be a uniform preparation, yielding 12 per cent. of oil on treatment with ether. The protein amounted to 4·40 per cent. and the mineral matter to 1·12 per cent. It showed the same degree of concentration as the plain extract and a similar digestive activity. We could trace no malt substitutes.

EXTRA STOUT.

(WHITBREAD AND CO., BRITANNIA-STREET, KING'S CROSS, LONDON, W.C.)

We had occasion some years ago to comment upon this stout as an example of a malt liquor which had not been artificially carbonated. We are of opinion that artificially carbonated beer is not so satisfactory dietetically as beer containing the natural gas from fermentation. We have re-examined this stout and the results show that its quality is maintained. It possesses the same alcoholic strength, exactly the same amount of proteins, the same amount of phosphates, but a slightly diminished amount of malt extractives. It is in sound ripe condition and free from excess of acidity and possesses a mild soft flavour.

MEDICINE AND THE LAW.

New Regulations affecting the Sale of Some Poisons.

IN THE LANCET of Oct. 7th, p. 1034, reference was made to the inquest upon a young man who had apparently committed suicide by drinking hydrochloric acid. It may have been noticed that in some of the accounts of the inquest given in the newspapers a witness was reported to have said that a new Act of Paliament, coming into force on Oct. 1st, would put a stop to poisons of the character indicated being freely sold by oilmen. In the evidence referred to the allusion was probably not to an Act of Parliament, but to regulations of the Privy Council recently made which came into force at the beginning of the present month and were briefly referred to on p. 1049 of the same issue of THE LANCET. These regulations are such as can be made at any time by the Privy Council under the fifth section of the Poisons and Pharmacy Act of 1908, which, among other things, forbids the sale by retail of any substance to which the section applies, unless the "box, bottle, vessel, wrapper, or cover in which the substance is contained is distinctly labelled with the name of the substance and the word 'poisonous' and with the name and address of the seller of the substance, and unless such other regulations as may be prescribed under this section by Order in Council are complied with." Two new regulations now affect the sale of the poisonous substances referred to, the first of which, it will be observed, applies to any such substance, whether liquid or not, and the other to liquid substances only. Firstly, in the retail sale of "any substance" to which the section applies the label referred to in the section cited above is to bear the additional words, "not to be taken," which are to be "distinctly printed" thereon. Secondly, in selling retail any "liquid substance" to which the section applies, "such substance shall not be delivered or sent out except in bottles or containers rendered distinguishable by touch from ordinary bottles and containers." These provisions are not difficult to comply with, but care will have to be taken that they are observed strictly. We do not go so far as to say that if the word "poison"—more usually used than "poisonous" in such a connexion—be printed upon the label a serious offence is committed against the section, but at the same time a fine not exceeding £5 may be imposed for any infraction, and according to the section "poisonous" is the word which ought to be used and not "poison." The word "printed" is not employed in the section with regard to the label, perhaps because many vendors find it convenient to keep labels bearing the words "poisonous" and their name and address printed on them, and are in the habit of adding in writing the name of the substance sold. We do not say that this is desirable, but only point out that the section says the substance must be "distinctly labelled," whereas under the regulation the words "not to be taken" must be "printed." In the second regulation "rendered distinguishable by touch" is not very explicit, but at all events the use of the fluted bottle long associated with the sale of poisons by druggists is an obvious compliance with the rule, and an ordinary "container" of any kind such as is commonly used for holding non-poisonous liquids will be illegal. Another Order in Council under the same section will come into force on Feb. 1st of next year enlarging the scope of the section by adding to the substances to which it applies "liquid preparations containing more than 5 per cent. by weight of free ammonia." The section originally affected the sale of sulphuric acid, nitric acid, hydrochloric acid, and soluble salts of oxalic acid, provision being made for addition to the list by Order in Council. The regulations described above seem to render accidents with poisonous substances less likely to occur, but the use of them by persons determined to commit suicide is not affected.

The Carrying of Pistols.

The necessity for stringent legislation against the easy purchase and promiscuous carrying of pistols is emphasised by the following cases, all reported in a single copy of a weekly newspaper published on Oct. 14th: 1. The murder of a stationmaster at Lintz Green, a village near Newcastle, apparently shot with a pistol by a man whose motive was robbery. 2. The suicide of a foreign woman who shot herself with a revolver in a hotel, a verdict of suicide being returned by a jury in the Westminster coroner's court. 3. The wounding of a constable in Oxford-street by a man who had attempted to rob a shop, the window of which he had broken with a brick. The person who fired the shot escaped, but a man arrested on another day and charged with the offence was remanded at the police court after evidence had been given that when arrested he had upon him a magazine pistol loaded, a spare magazine also loaded, and 28 loose cartridges. 4. A man summoned and fined £4, with 4*s*. costs, for being found in possession of loaded firearms and also for discharging a revolver. He appears to have made some threat about shooting when hiring a taxi-cab, and after arriving at his destination to have entered a house and discharged his weapon from an upper window. Before being sentenced he was remanded for a week in order that he might be medically examined, but eventually evidence was given to the effect that he was sane, and the penalty mentioned was imposed. A case in which serious allegations of assault and intimidation are made against a number of men is not included in this list, but is one which, whatever its issue may be, is instructive as to the familiarity of youths of the rougher classes with dangerous weapons. Law-abiding citizens and the police are alike entitled to better protection than they now have.

Death from Drinking Carbolic Acid.

The accidental drinking of carbolic acid is a not infrequent cause of death or injury, but the facts shown at the inquest upon a young stockbroker, Mr. Hubert A. R. Burrough, at Barking recently were of an unusual description. He appears to have gone on board a French vessel, the *Bougainville*, lying in the Thames, with four other persons not connected with the ship and to have inspected her, after which all were invited by the captain into his cabin, and glasses were brought. The captain finding that a bottle containing port which had already been opened had not sufficient wine in it, went to his sleeping cabin and took what he believed to be a fresh bottle from a cupboard. It has been a regulation on board French ships that carbolic acid should be carried for purposes of disinfection, and that it should be in bottles having a red label with a statement of the contents of the bottle and of their dangerous character. According to his evidence the captain took from the cupboard a bottle of the shape of a port bottle and having a black seal, and from it filled the glasses. All present simultaneously raised their glasses in response to a toast, and had swallowed enough to render five of them seriously ill and to cause the death of Mr. Burrough before they discovered that instead of wine they were drinking carbolic acid. That its characteristic odour was not detected by any of them before drinking was partly accounted for by the statement that the vessel was laden with chemical manure, and no doubt the fact of a toast being proposed and an effort made to drink simultaneously contributed. At the same time it is remarkable that accidents should so often occur through the drinking of liquids containing carbolic acid, ammonia, and other drugs the odour of which might be expected to compel the consumer's attention. At the inquest on Mr. Burrough it was stated that another form of disinfectant has recently been substituted for carbolic acid on board French vessels. The verdict of the coroner's jury was one of accidental death.

THE LANCET.

LONDON: SATURDAY, OCTOBER 21, 1911.

The One-Portal System.

IT is an open secret that evidence has been given recently before the Royal Commission sitting to inquire into the affairs of the University of London, the effect of which has been to bring to the notice of the Commissioners the advantages which might be reaped by the University if some scheme of fusion between that body and the Royal College of Physicians of London and the Royal College of Surgeons of England with regard to their respective medical curricula could be brought about. It is obvious that in London (and for the moment we are considering London only) the same representatives of medicine, surgery, and midwifery, and other subjects teach and examine at the University and the Royal Colleges, while the organisation of medical education in London is largely—and admirably, it should be added—controlled by the same individuals. Yet there are separate boards of examiners appointed by the University and the Royal Colleges in all branches of study, as well as separate examinations. This obviously expensive position, leading alike to an unnecessary multiplicity of examinations for the hardly-pressed students, as well as to a great waste of time for all concerned, has been seriously considered by both the English Royal Colleges, while the Chancellor of the University of London has been for the past two years in possession of the views of the governing bodies of the Colleges. These views, as readers of THE LANCET know, indicate the desirability of a certain coöperation between the Colleges and the University, if a joint scheme can be arrived at under which neither the prestige of the University would be endangered nor the corporate privileges of the Colleges sacrificed. Whether anything will definitely result from such communications as have yet passed between the Colleges and the University is doubtful, but what is not in doubt at all is that the liberal attitude of the Colleges makes that favourite conception of all medical reformers, the one-portal system, a genuine possibility again.

There was a time not long ago when we were forced to class the one-portal system as a dream, having regard to the imminent creation of new universities and the probable opposition of the Royal Colleges. But circumstances have combined to cause many of those who have the best interests of medicine at heart to estimate the one-portal system as the solution of the more difficult of the problems that now vex sorely medical education; and those who see in the one-portal system merely a desire for something new, a wild attempt to attain an unnecessary form of symmetry in affairs essentially unsymmetrical, are exactly the opponents of the one-portal system who should recognise the force of precedent. For their sakes we point out that a little over 30 years ago the one-portal system of medical education was nearly established after years of negotiation by representative officials appointed by the English universities and medical corporations. In 1878, when these negotiations were practically complete, the following distinguished men were representing the contracting bodies: Sir HENRY ACLAND and Sir GEORGE ROLLESTON, the University of Oxford; Sir GEORGE PAGET and Sir GEORGE HUMPHRY, the University of Cambridge; Dr. G. H. PHILIPSON (the present Sir GEORGE PHILIPSON) and Dr. GEORGE Y. HEATH, the University of Durham; Sir RICHARD QUAIN and Dr. W. B. CARPENTER, the University of London; Sir J. RISDON BENNETT and Sir HENRY PITMAN, the Royal College of Physicians of London; Sir JAMES PAGET and Mr. JOHN MARSHALL, the Royal College of Surgeons of England; and Mr. EDWARD BRADFORD and Dr. GEORGE CORFE, the Society of Apothecaries of London. The scheme went through many vicissitudes, partly due to difficulties connected with the charters of various bodies and partly due to jealousies arising through the proposed appointments of representatives on the governing body and on the Board of Examiners. At last, however, all was settled harmoniously and the General Medical Council agreed to recognise a conjoint scheme which as far as England went would have been a one-portal system. Alas, by the withdrawal of one of the bodies, this prospect was ruined. How much simpler and better would the method of qualification be now but for the withdrawal of that one body! For if the one-portal system had been established then there is little doubt that the creation of new universities would have only added to its strength. And this scheme, moreover, was not for England only, although it is true that in England alone were the details complete. In Scotland and in Ireland systems were in the course of creation on identical principles. The scheme was this. The universities, of which there were then but four, were to appoint representatives on a body called the Committee of Reference formed by the Royal Colleges of Physicians and Surgeons and by the Society of Apothecaries. These three bodies were to conduct a one-portal examination with the sympathy and advisory influence of the universities, and the universities agreed not to grant their degrees in Medicine and Surgery to anyone who had not passed this one-portal examination. At the same time the universities reserved to themselves the right to exact such further conditions for their degrees as they thought fit, and the corporations reserved the same right in regard to their diplomas. The degrees of the universities were therefore to be not qualifications to practise, but academic distinctions—clearly what they ought to be.

We bring the consideration of the one-portal system before our readers, then, as a policy which after all may be the practical one. No one denies that the multiplicity of educational bodies able to give students the right to practise medicine is an undesirable thing; it leads to complications in professional life as well as to a plethora of examinations and a mass of useless labour and routine, while it entails upon the General Medical Council very delicate work in standardisation. The General Medical Council has statutory power to recognise any combination of bodies for conducting a qualifying examination in medicine, surgery, and

midwifery. A former scheme for a one-portal system has so nearly succeeded that careful followers of precedent need not feel that in supporting a movement towards a general combination they are doing anything dangerously experimental. The Universities of Oxford and Cambridge may be trusted to uphold the principle that their medical degrees are academic acquirements and not licences to practise. Our belief is that if the University of London and the English Colleges can arrive at a basis of agreement, the one-portal system with its many advantages might be found by all the other qualifying bodies to be the remedy for admitted difficulties in medical education.

The Harveian Oration.

IN delivering the Harveian oration for this year before the Royal College of Physicians of London Dr. C. THEODORE WILLIAMS chose as his subject one that fully carries out HARVEY'S injunctions to exhort "all Fellows and Members of the said College to search and study out the secrets of Nature by way of experiment." There is probably no one condition that has been more carefully studied in all its aspects than pulmonary tuberculosis—its etiology, pathology, and treatment, both curative and prophylactic, have received attention from physicians and scientists for generations. In a masterly and scholarly manner Dr. WILLIAMS considers the progress of knowledge in regard to pulmonary tuberculosis since the time of HARVEY, dwelling more particularly on treatment. If we take a general survey of the therapeutics of the disease since that time, we can conveniently review the principal measures which have been introduced in three periods, the first being reckoned from the earliest date until 1882, when KOCH'S classical experiments determined the causation of the disease by the tubercle bacillus; the second period extending from then until 1890, when tuberculin was introduced; and the third from that time to the present.

Before the discovery of the tubercle bacillus the treatment was necessarily empirical in character, the true etiology of the disease not having been determined. Nevertheless, occasionally there was an interesting rehearsal of future methods. Noteworthy is an "Essay on the Treatment and Cure of Pulmonary Consumption," by GEORGE BODINGTON of Sutton Coldfield, published in 1840. In THE LANCET of July 11th, 1840, we published a review on the work in which we remarked: "The modest and rational preface with which the author introduces his pamphlet on pulmonary consumption has so far influenced us that we shall merely give an outline of his principles without expending any portion of our critical wrath on his very crude ideas and unsupported assertions ..... The measures, then, which Mr. BODINGTON assures us have been 'uniformly and completely successful in the treatment of several cases of tuberculous consumption' are detailed in the following passages. ..... More agreeable or seductive medicaments could not certainly be found in any pharmacopœia: fresh morning air to make the patient breathe; good wine to bring down his pulse, a good dinner to make him fat, and an opium pill to make him sleep." This was truly prophetical of the future "sanatorium treatment" combined with measures likely to prevent auto-inoculations. Dr. WILLIAMS also draws attention to the remarks of SYDENHAM, "the great physician of gout and fevers," who, after giving a rather striking sketch of an advanced case of pulmonary tuberculosis, describes a less acute case, and considers that the treatment "which would suffice would be to abstain from meat and wine for a few days and to take a balsam of sulphur and anise with sugar in the form of tablets and then a cough mixture of oil of sweet almonds, syrup of maidenhair, and syrup of violets, this to be taken off a stick of liquorice." SYDENHAM likewise forecasts the use of active exercise, for he says: "Of all the remedies for phthisis, long and continued journeys on horseback bear the bell. ..... Bark is no surer a cure for ague than riding for phthisis." Dr. WILLIAMS then dwells rather fully on the treatment of consumption at the time of LAENNEC, LOUIS, JAMES CLARK, and others, in order to show that the short duration of life in their cases was closely connected with the depressing measures—e.g., bleeding and emetics—then in vogue, and that the disease was not, as has been urged, of an utterly different type from that which now prevails when the duration of life is much greater. Dr. WILLIAMS also refers to the introduction of cod-liver oil, which, he asserts, has exercised a wonderful effect in the outlook of the disease. After the discovery of the tubercle bacillus efforts were made to kill the germ directly by means of bactericidal drugs taken by the mouth, inhaled, introduced directly into the air passages, and injected into the veins or subcutaneous tissues. Very many substances were employed, and although success has been claimed by some observers, in the hands of others satisfactory results were not obtained. Indirect measures were then adopted which were supposed to act by rendering the soil unsuitable for the growth of the bacillus, or, in other words, by "increasing the resistance of the patient"; this is a vague term which has received various explanations. Foremost amongst these measures was the open-air or sanatorium treatment. Dr. WILLIAMS gives a brief history of the movement, which was at first elaborated at German institutions. The various phases through which the sanatorium method has passed are well known. BREHMER and DETTWEILER were amongst the earliest pioneers, the latter in particular laying stress on the importance of rest. He established the "Liegehalle system." WALTHER of Nordrach took an opposite view and enjoined outdoor walks, whilst M. S. PATERSON, medical superintendent of the Brompton Hospital Sanatorium at Frimley, has evolved a system of graduated labour which has been attended by encouraging results. Dr. WILLIAMS also comments on the favourable effect of mountain climate in suitable cases. The introduction of tuberculin by KOCH once again raised hopes that a specific remedy against tuberculosis had been found. The earlier results, however, were disappointing, but within recent years numerous modifications of the original substance have been made and tried, and at the present time in one form or another tuberculin is being extensively employed. The modern view of treatment by this method

differs considerably from that formulated by KOCH. As originally used, tuberculin occasionally produced a stormy reaction, giving rise to dangerous destruction of tuberculous tissue and even setting free tubercle bacilli. It is now found, however, that an immunising response can be obtained without causing a reaction, namely, by using very minute doses, which produce the desired effects—toxic immunity and local hyperæmia. The exact technique employed by different physicians varies, as also does the composition of the remedy. Dr. WILLIAMS urges further investigation, but expresses the opinion that such observation should be carried out in a hospital or sanatorium rather than at a tuberculin dispensary. He also refers to the theory of auto-inoculation which has been advanced by A. C. INMAN and M. S. PATERSON to account for the benefit produced in those patients undergoing treatment by graduated labour.

In conclusion, Dr. WILLIAMS discusses the prophylactic measures which have been adopted in the crusade against tuberculosis. That the decrease in the incidence of the disease has been in large measure due to improved drainage, more cubic space, and less overcrowding there can be no doubt. The problem of the housing of the working-classes is one of the chief elements in the prevention of tuberculosis. The education of the masses in the principles of cleanliness and ventilation is essential, for if the population as a whole is aware that these principles are necessary for the prevention of the disease a powerful factor for good will have been established. In order to combat tuberculosis two principal achievements are required: the first, to establish immunity against the disease (this must be done by collaboration of the physician and the worker in the laboratory); the second to improve sanitary conditions, not only in large cities but also in villages. The remarks of Dr. WILLIAMS in this year's Harveian Oration will be an incentive to further labours on the part of all those who are genuinely anxious to assist in the conquest of what is still one of the most fatal of maladies.

The National Insurance Bill.

OUR admirable contemporary, the *St. Bartholomew's Hospital Journal*, publishes this month three articles and a prefatory editorial note, which together amount to a symposium on the National Insurance Bill. Dr. CHRISTOPHER ADDISON, who speaks with the fullest knowledge of the Chancellor's intentions as well as of his actions, contributes an article in support of the Bill, and incidentally explains his own attitude towards the vexed question of the income limit. Mr. T. J. VERRALL, who has recently come forward as a candidate for the vacant post of Direct Representative for England on the General Medical Council, and who may be taken as speaking for the leaders of the British Medical Association, writes of the present state of the Bill in terms of qualified approval. Mr. VERRALL makes the very good point that Mr. LLOYD GEORGE and the public must be told that the profession "not having sought this modification of its mode of practice is even less disposed to bind on itself fetters of inadequate pay." Lastly, there is a breezy unsigned article entitled, "The £2 per week Income Limit," which claims to speak from inside knowledge. This sharply criticises the alleged action of a committee meeting of the Representatives at Birmingham under the chairmanship of Mr. VERRALL, and accuses the British Medical Association of giving way on the essential point of the demand for an income limit. The anonymous writer, indeed, suggests that the withdrawal of Sir PHILIP MAGNUS'S amendment and the passing of Dr. ADDISON'S amendment would never have happened unless the Chancellor of the Exchequer had been given to understand that the medical profession had "climbed down" on the question of the income limit. The circumstances narrated for the first time in the third article and the inferences drawn from them would certainly not pass unchallenged if the article were supported by a signature. According to the editor of the *St. Bartholomew's Hospital Journal*, the writer suggests that "the bulk of the profession has been kept ignorant of a want of firmness on the essential of an income limit in the Bill." We believe, however, that according to Mr. LLOYD GEORGE there was never any intention on his part to agree to an income limit.

These three articles seem to us to reveal only more clearly the position of deadlock which we have indicated in our recent surveys of the progress of the National Insurance scheme. On the one hand, the British Medical Association has stated more than once, and now most explicitly,[1] that it will not modify in any way the policy which has been formulated by it and approved by the profession. This is the more necessary because one of the original and most vital of the six cardinal points of the Association's policy has already been set aside by the vote of the House of Commons: we refer, of course, to the demand for a £2 per week wage limit for all insured persons. On the other hand, evidence is daily accumulating that the leaders of the Friendly Societies have no intention of relaxing their demands for the control of the administration of medical benefits. Thus, at the annual meeting of the National Conference of Friendly Societies, which was held last week at Edinburgh, the delegates, "representing over 4,000,000 benefit members of Friendly Societies in the United Kingdom," passed resolutions to this effect, and further resolved that in the event of Parliament not conceding their minimum demands they would recommend the whole of the societies throughout the country strenuously to oppose the passing of the Bill. It seems clear, therefore, that the Chancellor is faced by two ultimatums. Without the support of the medical profession he cannot work his scheme. He has not yet won this support by granting all their demands. Nevertheless, what he has already done to reconcile the medical profession has raised a storm of angry protest among the members of the Friendly Societies, which grows fiercer and more menacing as the Autumn Session approaches. Whatever may be the political results of their insistence, the medical profession at least will not give way.

Annotations.

"Ne quid nimis."

THE BRUSSELS SURGICAL CONGRESS.

THE Third Triennial Congress of the International Society of Surgery, which was held at Brussels from Sept. 26th to 30th, proved to be quite as successful as those which had preceded it and fully maintained the high standard reached by previous sessions. Indeed, in one respect at least it was more satisfactory. At the second Congress the wide range of subjects chosen for discussion and the large number of speakers rendered the completion of the programme somewhat difficult. On this occasion, however, the arrangements obviated any such difficulties and provided ample time for the due consideration of the various papers and reports. The formal opening of the Congress was performed on Sept. 26th by M. Berryer, the Belgian Minister of the Interior, and the scientific proceedings were inaugurated by a presidential address from Professor Lucas-Championnière. The President referred briefly to the great advances made by surgery during the past century and the opening years of the twentieth century, and indicated the marked changes that have come about even in the short space of time which has elapsed since the last Congress. The President paid a particularly warm tribute of affection and admiration to Lord Lister. A large number of valuable papers on surgical and allied subjects were read during the sessions of the Congress, and they were followed in many cases by interesting discussions. The reports on the treatment of chronic colitis were entrusted to Professor Paul Segond of Paris, to Professor C. L. Gibson of New York, and to Mr. D'Arcy Power, the British representative on the International Committee. We hope to publish in an early issue an account of this and other features of the Congress. British visitors to the Congress were especially struck by the generous hospitality which was freely offered by the inhabitants of Brussels to the members, and they cannot speak too highly of the warmth of their welcome and the excellence of the entertainments provided for them by their hosts. Professor A. Depage, who has up till now filled the onerous post of secretary, and to whom the success of the society is so largely due, was chosen as President of the next Congress. This is to be held in New York in 1914, when the subjects for discussion will be (1) Surgery of the Duodenum; (2) Plastic Surgery; and (3) the Technique of Amputations. Only one note of regret is to be sounded with regard to the Congress of 1911, and that is that there was not a much larger attendance in the British section. Seventeen members attended the meeting in 1908; 24 in 1911.

MEDICAL EQUIPMENT FOR MERCHANT SHIPS.

THE committee appointed by the Board of Trade, at the request of the General Shipowners' Society of London, to consider medical scales for merchant ships has gone carefully into the whole question, and has recommended four revised scales for adoption in place of those now in force. For ships which will have a medical officer on board, including emigrant ships, two separate scales are drawn up—one for those in the North Atlantic trade, where voyages are short and numbers of passengers and crew are large, the other for those ships which with smaller passenger lists go longer voyages abroad. For each of these classes the necessary instruments are detailed, including a steriliser large enough to take a pair of long midwifery forceps. It has not been thought necessary to recommend a microscope and bacteriological outfit such as are required in the larger steamers of some foreign Powers, but the equipment of instruments and appliances for clinical work has been modernised, and it is recommended that an endeavour be made to secure the appointment of a second medical officer to ships with a crew and passenger list of 1500. It is further noted that the professional care of these large numbers would be facilitated if a qualified dispenser also were employed. The other two scales are intended for merchant ships which do not carry a medical officer and for fishing boats. One scale applies to all merchant ships whose voyages ordinarily last more than five days, the quantities of the medicines they are to carry being based on the number of men in their crews. The other, named an emergency scale, for vessels never more than five days away from harbour, applies to all other sea-going ships; but coasting craft whose voyages last no more than 24 hours may either conform to the emergency scale or carry the ambulance hamper of the St. John Ambulance Association or something similar. Anti-diphtheritic serum, sealed and dated, is to be carried by all emigrant ships, and a germ-proof filter by all that go to sea for more than five days. An improved carron oil, antisepticised by eucalyptus or other essential oil, might have been recommended, but the selection of drugs and preparations has been well made and marks an advance. Attention is drawn to the dangers which arise from the indiscriminate sale on board ships of patent medicines, sea-sickness specifics, and the like. But the most important recommendation of the committee, apart from the scales, is that which draws attention to the need for separate and reserved accommodation in cargo vessels for men of the crew who have fallen ill or been injured. We trust that the Board of Trade will adopt this recommendation, which would involve the provision, adjacent to the officers' cabins in the after part of every ship, of a spare cabin of about 250 cubic feet definitely allocated as a hospital and so marked, to be examined by the sanitary inspector on his periodical visits and reported in good order, and kept ready for its special uses and in no other way employed.

INFANT MORTALITY IN AMERICA: AN URGENT CALL FOR ACTION.

AN Association for the Study and Prevention of Infant Mortality has been founded in the United States, and at its first meeting at Baltimore an address was delivered by Mr. Edward B. Phelps setting forth the present appalling waste of infant life in that country, and suggesting the establishment of day nurseries as the best known means of reducing it. In the treatment of this subject, so far as it concerns the United States, the writer labours under the disadvantage that the vital statistics of that country are by no means complete; and this is particularly true respecting the returns of birth and of mortality. That this is the case Mr. Phelps is constrained to admit. Very early in his address he propounds the question, "What is, or has been, the infant mortality of the United States as a whole?" and he answers the question by saying that "Nobody knows, and there is no means of finding out." Mr. Phelps quotes the opinions of several European authorities, including Sir George Newman in this country, and Dr. Cressy Wilbur and Dr. L. Emmett Holt of New York, from whom he gathers the conclusion that the present sacrifice of infant life all the world over amounts to not less than 13 in every 100 live births. He further emphasises, what is familiar knowledge, that this can only be an average figure, as amongst the less favoured sections of every community infant mortality is certainly much higher than this. The excessive waste of infant life in the United States, as in this country, is mainly

the result of three obvious conditions—poverty, ignorance, and neglect, the evil effects of which by no means terminate with the first year of life. Says Mr. Phelps: "The same conditions which cause the death of 13 out of every 100 born ..... leave more or less stamp on perhaps two or three times as many more babies who somehow manage to crawl over the infant dead line, many of whom will be the fathers and mothers of the next generation. The problem of infant mortality, therefore, is far more than one as to means of decreasing the number of infant deaths. Its scope is worldwide, and on its partial solution, at least, depends the welfare of posterity. The 'call for action' on such a problem may fairly be termed urgent." We quite agree with Mr. Phelps.

PRURITUS ANI.

PRURITUS ani is so distressing a complaint and the treatment of it has hitherto proved so unsatisfactory and uncertain, that any new light thrown upon its nature should be welcomed. Dr. Dwight Murray, of Syracuse, N.Y., read a paper on the subject before the recent meeting of the American Proctologic Association at Los Angeles, which gives food for reflection and further observation. In the first place, he took occasion to separate true pruritus ani, a most intractable condition of uncertain causation, from other anal complaints provocative of itching, such as fissure, ulcer, diseased crypts, pediculosis, and so forth, which are more amenable to treatment directed to the cause. The skin about the anus in all cases of true pruritus, he says, is always thickened, radiating in folds, in most cases macerated and lacking pigmentation, parchment-like, and fissured. There is a general tendency to nightly periodicity, the itching recurring with considerable regularity, and no relief is obtained by scratching. During 1910 Dr. Murray had cultures made of all the cases, 19 in number, that presented these characteristics, and found streptococci present externally on the skin in every case. A similar investigation of five other cases of rectal disease showed a very few streptococci in one case only, the other four being entirely free from this micro-organism. A blood test in each of the pruritus cases further showed that the patient's resistance against streptococci was low, while it remained high for other micro-organisms. Starting from these premises, Dr. Murray and his associate, Dr. F. M. Meader, bacteriologist to the Syracuse Medical College, treated eight of these cases with an autogenous vaccine, with the result that itching ceased, reaction to the injection was restored, and streptococci ceased to be found in smear and swab, after a period of treatment varying from the first to the eighth injection. In one case a lowered resistance to bacillus coli was also found, and in this case vaccines of both organisms were used. In several cases a change in the character of the itching was noticed first. Dr. Murray's series of cases all occurred in males; he has only two records of true pruritus in women, and concludes that women are less frequently affected with it than men. It is possible, he thinks, that the infection often penetrates the skin, in which case relapse would be liable to recur until the germs are entirely eliminated. It has occurred to him also that possibly other parts of the body may become infected from this source, and that to it may be traced some instances of puerperal fever, erysipelas, and other streptococcic diseases. He concludes, therefore, that pruritus ani may have streptococcic infection as its primary cause or as a secondary cause after the passing away of some other primary cause; that the streptococcic-infection theory seems at any rate to have a practical value for the patient and medical man; that other organisms, especially bacillus coli, may complicate the infection; and that an autogenous vaccine made from a culture of the offending germ, with or without auxiliary palliative measures, offers the best hope of cure. He is confirmed in these opinions by later observations to be presently published. The matter is one that lends itself to investigation, and there should be no difficulty in obtaining a sufficient body of evidence from various sources to establish the truth or otherwise of his deductions and the efficacy of the treatment that he proposes for more extended trial by the medical profession.

THE USE OF BAER'S MEMBRANE FOR THE MOBILISATION OF ANKYLOSED JOINTS.

IN the *Boston Medical and Surgical Journal* of July 20th, Dr. R. B. Osgood has reported from the orthopædic department of the Massachusetts General Hospital three cases which show the possibility by means of Baer's membrane of preventing reunion in joints that have been mobilised after bony ankylosis of several years' duration. Baer's membrane is obtained from the bladder of the pig, sterilised, and chromicised, like catgut. It is supposed to remain in the body for 30 days before it is absorbed, but Dr. Osgood has seen it still unabsorbed and strong 11 weeks after insertion. In the first case the patient was a single woman aged 26 years. At the age of 8 years she suffered from polyarthritis after typhoid fever and at 10 from "rheumatic fever," which was followed by chronic arthritis of most of the joints. This had remained persistent ever since. Physical examination revealed nothing except chronic arthritis, which seemed to be quiescent. She could open her mouth only a quarter of an inch, and the movement seemed to be wholly in the left articulation. On Nov. 17th, 1909, Dr. E. G. Brackett tried to break down the adhesions under ether, but they did not yield to as much force as he thought safe to apply. On Nov. 21st he made an incision, 1½ in. long, forward from the right auditory meatus, and a second incision, ¾ in. long, downwards from the same point. The subcutaneous tissues were dissected back, exposing the lower margin of the zygoma and upper portion of the ramus. With a narrow osteotome the condyle was excised and the end of the ramus was rounded and shaped. Baer's membrane was wrapped around the ramus and retained by catgut sutures, and the wound was closed. Two days later the patient could separate her jaw half an inch more than before operation and there was no severe pain. The wound healed by first intention, and she was discharged on the twenty-fourth day able to separate the jaws over an inch. On Jan. 27th, 1910, she was readmitted. The motion had increased slightly, but recently a swelling had appeared in the region of the wound and broken. Since this time there had been a slight sero-purulent discharge which was greater at night. On slight pressure bloody, creamy pus exuded. On Feb. 10th the sinus was enlarged by a small incision, and the membrane, still tough and intact, was removed. She was discharged, and a letter, dated March 21st, was received, stating that the wound had healed and motion remained good. In the second case the patient was a youth, aged 19 years, whose knees were ankylosed at 25°. He suffered from poliomyelitis in childhood, and a surgeon performed double excision of the knee and removed the patellæ. The ankylosis followed. It seemed best to straighten and stiffen one knee, since all power was lost in both quadriceps in consequence of old poliomyelitis, and to mobilise the other. This would enable him to rise more easily from the sitting posture, the hamstrings still showing some power of contraction on the side in question. On Feb. 4th, 1909, Dr. Brackett straightened the left knee by removal of a wedge of bone. Firm union resulted. On Feb. 18th a U-shaped incision, with convexity downwards, was made over the right knee, and the flap turned up by dissection from the bone. With a blunt dissector a small

opening was made posteriorly between the vessels and the bone just above the line of the old excision. Through this opening was pushed the flexible blade of an ordinary carpenter's coping saw, teeth upward. The femur was sawn through from behind forward, making a convex lower end. About a centimetre of bone was removed from the tibia, leaving the end concave and loosely fitting the end of the femur. The ends of the femur and tibia were each covered with Baer's membrane, which was secured with silk sutures. The wound was closed and a posterior wire splint was applied. After two weeks the splint was removed and the mobility was found to be free and attended with little pain. Healing had taken place by first intention. A split plaster splint was applied from the toes to the groin. Gentle passive motion was performed daily. After a month a slight serous discharge began and continued for a month. Passive movement to 90° was possible and almost painless. After two months a calliper splint with a knee-cap was applied and weight-bearing was begun. Daily passive movement with massage was continued. At the end of three months there were full passive flexion to nearly 90° and marked lateral mobility. As there was no quadriceps there was no voluntary extension, but voluntary flexion was possible. The patient was given a steel brace jointed at the ankle and knee, with a drop catch at the latter, ensuring rigidity in walking and allowing flexion in sitting. With this he got about by the aid of two canes. A second operation—implantation of silk ligaments—was performed to produce greater stability of the well-established flail joint. The final result was that he could get about with a brace and one cane and rise easily from the sitting posture. In the third case a man, aged 23 years, had bony ankylosis of the elbow in a straight position, with total loss of pronation and supination, the result of a compound fracture in childhood. A similar operation to those described was performed. Complete extension, voluntary flexion to 120°, and a few degrees of pronation and supination were restored, so that the arm was useful. In all the cases a serous or slightly purulent discharge occurred from some portion of the wound in from three days to four weeks after the operation.

PHYSICAL TRAINING IN SECONDARY SCHOOLS.

THE Welsh Department of the Board of Education has recently issued a circular on physical training in secondary schools for the information and guidance of school authorities in Wales.[1] The Board wisely recognises that physical training should always be at least as much a question of school hygiene and of medical science as of educational organisation in a more limited sense, and that this is especially true in the case of secondary schools. It is therefore anxious that due attention should be paid to the subject by school authorities in order that the organisation and technique of physical training may be based on sound principles. The object which the Board has in view is the careful and well-balanced cultivation of the physical powers of each individual child; and this, it believes, can only be attained, so far as physical exercises are concerned, by the appropriate application of a graded system of exercises, founded on physiological principles and adapted to the age, needs, and capacity of each pupil. The memorandum has been prepared by the medical department to the Board of Education and is signed by Sir George Newman, the chief medical officer. It opens with an admirable account of the interrelation between mental and physical training in the true education of the growing child. The mental and moral effects of physical training are clearly summarised, and a special point is made of the healthy public spirit which is encouraged by the combined efforts and coöperation of a number of children. The memorandum next refers in some detail to the effects of physical exercises on the growth and development of the brain, through the intimate connexion between the brain and the neuromuscular system. It also points out that the recreative effects of physical training are of great value, apart from their disciplinary effects, and that if a lesson, which is really a game, is not thoroughly enjoyed many of the desired results will be lost. Physical training in the strict sense of the term is defined as the application of methodical and formal exercises for the purpose of securing certain definite and controllable effects, and its importance as a supplement, as a preliminary, and as a corrective to general athletic sports is insisted upon. Of the various systems of physical exercises the Swedish is held to be the best for use during school life, since it develops all parts of the body harmoniously according to physiological principles. Having enumerated the advantages of the Swedish system the memorandum recommends that all secondary schools should adopt it. But a note is added that the value of Swedish exercises is greatly diminished if they are not applied in accordance with the principles of the system. Useful hints are given on the construction and arrangements of a suitable gymnasium and on the organisation of classes. The teacher should possess expert training and should be a member of the regular school staff. In this respect girls' schools have the advantage of boys' schools, for at present there are extremely few English male teachers possessing such qualifications, while there are many expertly trained women teachers who are thoroughly competent to interpret the principles of Swedish exercises and also to supervise the games. As is repeatedly pointed out in the memorandum, the teacher is everything in physical training; ignorantly applied the Swedish system can work mischief. Although rule-of-thumb methods in arranging the progression of exercises in individual cases are to be deprecated, the exercises themselves are given definite forms in order to obtain definite effects, and any departure from them by a non-expert instructor should be discouraged. The memorandum concludes with a few valuable and suggestive notes on the relation of school medical officers to physical training. Whenever there is a routine medical inspection it is considered desirable that the arrangements for physical training should be to some extent under the general supervision of the school doctor, and that there should be close coöperation between the medical officer and the gymnasium instructor. Thus, the former would do well to familiarise himself with the system of exercises and with the effects which they are likely to produce, so that he may decide on the fitness of pupils for particular exercises, and may be alert for the symptoms of over-strain or other harmful effects.

TRAUMATIC RUPTURE OF THE RECTUS MUSCLE.

IN the *Journal of the American Medical Association* of Sept. 2nd Dr. M. A. Stern has reported an unusual injury—traumatic rupture of the rectus muscle. A man, aged 40 years, was pushing a heavily loaded truck from the platform of an elevator. The platform was several inches below the floor, so that when he pushed the truck on to the latter it rebounded and struck him in the abdomen. He felt pain at the time, but it passed off, and he worked for the rest of the afternoon. On the following morning he sought advice for intense pain over the seat of the injury. He walked in a stooping posture, which seemed to ease the pain. On examination he was found to be muscular and well nourished. There was moderate arterio-sclerosis. The pulse was of good volume and tension, and the temperature was 99·1° F.

The abdomen was exquisitely tender over a spot about 2 inches square, ½ inch below, and 1 inch to the left of the umbilicus. At this point there were swelling and rigidity. He was sent to hospital, where an ice-bag was applied. On the third day the pain had increased, rigidity and tenderness had become more localised, and the swelling had increased. At no time was there an abrasion or ecchymosis of the abdomen. Although there had been a good action of the bowels it was decided to perform exploratory laparotomy. An incision was made over the swelling. As soon as the rectus muscle was reached a considerable quantity of dark blood and clots welled up. The hæmatoma was wiped out and the left rectus muscle was found torn completely across and badly lacerated. Its sheath was intact. The peritoneum was opened, but no injury of any viscus was found. The muscle was sewn to the sheath and the bleeding points were ligatured. The abdomen was closed with drainage and good recovery ensued. Dr. Stern accounts for the rupture of the rectus without internal injuries by the fact that the man was struck when pushing a heavy load with both recti contracted to their full extent. The absence of any injury of the skin is also noteworthy.

THE DISTRIBUTION OF HOSPITAL COLLECTIONS.

AT the British Hospitals Association's recent meeting at Manchester the distribution of the Hospital Saturday and Sunday Funds formed the subject of an interesting paper by Mr. C. Hopkinson. He points out that those charged with the distributing of the sums collected for these funds in various localities have the choice of two theories upon which to proceed—viz., either to act on a presumption as to the wishes of the donors or to aim at such distribution as shall ensure the greatest possible relief to suffering. Obviously no direct evidence is available for aggregating and averaging the wishes of the respective donors, though assistance can be obtained from a consideration of the efficiency and economy in management, of the amount of work done by the respective institutions, of the individual hospital subscription lists, and of the poverty of particular institutions as measured by their annual deficit. The desire to get as much as possible for any expenditure, he says, is sufficiently general to suggest that the average donor will desire efficiency and economy of management to be taken into account in dividing contributions. The amount of work done by the institutions is an obvious factor, while the individual hospital subscription lists are a reliable measure of the importance of the several institutions in the public mind. The last factor he concedes to those who "might desire that the extravagance and consequent poverty of one hospital as compared with another, that the lethargy of one hospital as compared with another in collecting funds, should be favourable elements in considering distribution—the class, in fact, who would prefer to give a shilling to a beggar in rags on the way to the workhouse rather than to a decent workman to prevent him pawning his tools." To proceed on the second theory, Mr. Hopkinson says, it would be necessary to base conclusions on facts ascertainable from the statistics and accounts of the hospitals. The ideal method of carrying this out is that adopted by King Edward's Hospital Fund—viz., by competent lay and medical inspection. This method renders necessary the keeping of accounts on a recognised uniform system to facilitate comparison. It stimulates efficiency and economy of management, concentrates effort, and prevents overlapping. It is, however, hardly practicable in other towns than London. The writer recommends, with a view to the attainment of similar ends in smaller towns, the establishing by the Association of an annual standard cost per head (1) for a child in hospital; (2) for a convalescent in a convalescent home; (3) for medical and surgical in-patients, with an estimate of what would be a fair extra allowance per operation; (4) for each out-patient accident case; (5) for each ordinary out-patient case; and (6) for each home patient. He suggests the amount of work done as the basis of distribution, using the cost of that work at standard rates for calculating percentages so as not to put a premium on extravagance. A percentage, he thinks, should be deducted from all grants when the standard cost is exceeded, and in any case the grant should be limited to the amount of the true deficiency for the year. The method adopted in Manchester—viz., by taking the gross expenditure as a criterion, in place of the work done or of a standard expenditure based on the work done—he regards as highly unsatisfactory. The gross expenditure is taken of each hospital, and from that are deducted the aggregate receipts from invested funds, direct collections, profits from private nurses, payments for or by patients, and students' fees; and thus a nominal deficiency is arrived at in proportion to which the funds are distributed, the amount to be paid to any one hospital being limited to one-fourth of the Fund. On this system, as Mr. Hopkinson points out, it is quite conceivable that a hospital should be saving money and yet be receiving substantial grants, for no regard is paid to income from subscriptions or large donations. This, in fact, appears to have been the case in the past with the old infirmary, which at one time, while receiving grants, was annually investing money. At the present time, however, the new, enlarged, and entirely modern hospital shows, according to the Sunday Account Funds, a deficiency of more than one-third of the entire deficiency of the hospitals assisted, and yet it is allowed to receive only one-fourth of the fund collected. "Is it possible," asks Mr. Hopkinson, "to have a stronger condemnation of the method?"

SYPHILIS OF THE BLADDER AND OF THE UPPER URINARY PASSAGES.

IN the September number of the *Annales des Maladies Génito-urinaires* Professor M. N. A. Mikhailoff, of the Hélène Pavlovna Clinical Institute of St. Petersburg, has written on syphilis of the bladder. Until recently syphilis of the bladder and kidneys was never recognised except at a necropsy, but modern diagnostic methods have made it much less difficult to recognise during life syphilitic lesions in these organs. Professor Mikhailoff has described a case which was under the care of Professor Filling. The patient was a woman, 39 years old. She complained of a feeling of weight in the loins and of a periodic hæmaturia for the last five years. On examination she was very thin and anæmic. Thirteen years previously she had had a normal labour, and for 15 years the feeling of weight in the loins had been present. The hæmaturia already mentioned had become more abundant and frequent during the last two years, appearing every two or three weeks and lasting two or three days; it was not accompanied by any pain and the temperature remained normal. There was no tenderness of the abdomen. The specific gravity of the urine was 1090 and it was alkaline. Microscopically there were many urinary epithelial cells and a few pus cells. By means of the cystoscope the trigone was seen to be hyperæmic and the opening of the left ureter was dilated. Some groups of papules were also seen near the ureteral orifices, as well as on the upper and lateral walls of the bladder; each papule was covered by greyish-yellow scales. Wassermann's test was applied twice; on the first occasion the result was negative, but a week later it was positive. The patient was treated with mercurial pills and with iodide of potassium, and the bladder was washed out with a solution of boric acid. During the treatment the bladder was re-examined

by the cystoscope several times, and on each occasion improvement was seen in the condition of the mucous membrane. The quantity of urine also increased from 1000 c.c. to 1500 c.c. in the 24 hours. A month after the first cystoscopy the hæmaturia had ceased, and the mucous membrane of the bladder was almost normal. The positive Wassermann test and the results of treatment make the diagnosis certain.

ACTINOMYCOSIS IN NORWAY.

Professor Harbitz and Dr. Backer Gröndahl have recently published (*Norsk Magazin for Laegevidenskaben*, June) an account of the incidence of actinomycosis in Norway, where this disease has lately been carefully studied. The first case published in Norway dates from 1887, and for many years afterwards the disease attracted scant attention. More recently a number of cases have been reported from different parts of the country, and at the Pathological Institute in Christiania 87 cases have now been studied, with special reference to the source and course of the infection, as well as to the varieties of fungi found in different lesions. The seat of infection was the cervico-facial region in 39 cases, the lungs in 20, the abdomen in 26, and the skin in 2. The disease was twice as frequent in men as in women. Its incidence was not greater than usual in the months August to January. Many of the patients were town-dwellers, and most were recruited from the eastern and southern provinces, the west coast, including Bergen, being extraordinarily free from the disease. In the cervico-facial region the disease is chronic but benign and tends to spontaneous recovery. All the 39 patients so affected recovered. The primary focus in this class could seldom be found, but it was twice localised in the tongue, once in the submaxillary gland, and occasionally there was a history of aching gums early in the disease. In the lungs the disease was invariably fatal. The primary focus was in the pulmonary tissue: infection from the œsophagus to the lungs, as described by some writers, was never observed. Usually the first sign of the infection was a broncho-pneumonia. In the abdominal form 20 per cent. recovered. The primary focus existed in the appendix in nine patients, and this was also probably the case in five others. In these cases the appendix was usually scarred, or it presented a perforation leading directly to an abscess. The spread of infection may be intra- or extra-peritoneal. In the former case it often involves and perforates the bladder, when the fungi may be found early in the urine. In the latter case it may track up behind the diaphragm, and an empyema may be the first sign of an abdominal infection. Of the 2 cases of primary skin infection one occurred in a man who worked in a corn-field without stockings. He died in spite of radical treatment, including amputation at the thigh. Passage of the fungi by the blood-stream was occasionally observed in the later stages of the disease, when distant organs such as the brain and the lungs became involved, but spread of infection by the lymphatic system was never seen, and the authors emphasise the diagnostic value of this point. In 16 cases of actinomycosis hominis they succeeded in isolating one and the same facultative anaerobic fungus differing from that which most German writers have described as pathogenic (Boström's type). It also differed from every aerobic type cultivated from various plants. An identical growth was once cultivated from bovine actinomycosis, 7 cases of which were examined. Professor Harbitz and Dr. Gröndahl consider it probable, but not proved, that human and bovine actinomycosis are caused by the same or by closely allied fungi. Numerous attempts were made to isolate from corn, straw, hay, and the air the same anaerobic fungus; none but the familiar aerobic fungi could, however, be found, and these were not pathogenic to rabbits or guinea-pigs, nor could any progressive actinomycotic inflammation be induced. The writers locate the site of infection either in the lining of the respiratory tract or in the digestive tract which has been infected by swallowed matter. Less is known of the source of infection. Infection from cattle to man, or from man to man is not proved and is highly improbable. Probably the pathogenic fungi are derived from various plants; but how and where they live in nature is unknown. J. H. Wright has suggested that the fungus pathogenic to man and cattle does not exist elsewhere, and that it is often present in the mouth of man, becoming pathogenic with trauma. This theory is worthy of consideration, but it requires further support. The diagnosis of actinomycosis by complement fixation or agglutination was found by the writers to be impossible, and owing to the capriciousness of the disease and the variability of its course, it is difficult to estimate the value of the various remedies in use, including potassium iodide. Twice the writers used a vaccine made from sterilised cultures of the fungus; the treatment was quite negative in one case, and in the other case, which presented advanced abdominal disease, there was considerable improvement. The perusal of this interesting paper leaves the reader with the unsatisfactory impression that there are vast and numerous lacunæ in his knowledge of a disease which has commonly been treated by text-books as a cut-and-dried subject.

PLAGUE AND RATS AT SHANGHAI.

ONE of our Indian correspondents recently commented very fully on Dr. Arthur Stanley's report on the public health of Shanghai which has recently reached us. The details of the crusade against plague-rats which has been carried out in Shanghai deserves more detailed notice. In December, 1908, it was found that plague-infected rats were present in Shanghai; during 1909 and 1910 a complete plague survey of the settlement was carried out. The number of infected rats having been found to be increasing towards the end of 1910, a system of rat destruction was started, and over 18,000 houses were disinfected and made temporarily rat-proof. Owing to the vigorous action taken no outbreak resulted; six deaths only occurred. The number of cases is not stated; presumably it was six. Unfortunately there was considerable excitement among the Chinese population, leading almost to riot; in the end it was agreed that search for Chinese plague cases should be conducted by Chinese doctors from an independently instituted Chinese plague hospital, as is done in Hong-Kong. Dr. Stanley is quite clear as to the rat being the essential cause of plague epidemics, the flea (P. cheopis and C. fasciatus, especially the former) being the carrier; of the rats examined about 70 per cent. were M. rattus (in houses) and 30 per cent. M. decumanus (in sewers). Much work on the subject has been done in the public health laboratory, where over a thousand pathological specimens were examined, besides 19,000 plague cultures from rats.

A FURTHER Commission on Sleeping Sickness is about to be despatched to Nyasaland under the auspices of the Tropical Diseases Committee of the Royal Society. Colonel Sir David Bruce will be in charge of the Commission, and Lady Bruce will again accompany him to Central Africa. He will be assisted by Captain A. E. Hamerton, R.A.M.C., and Professor R. Newstead of the Liverpool School of Tropical Medicine, who are both already in Nyasaland. Sir David and Lady Bruce will sail from Marseilles on Nov. 10th. They will journey by the Zambesi and Shire rivers to Zomba,

the capital of Nyasaland. It is anticipated that the Commission will investigate sleeping sickness for three years.

Mr. J. Bland-Sutton has resigned the post of senior surgeon to the Chelsea Hospital for Women in order to devote himself more strenuously to his duties at the Middlesex Hospital.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

MEETING OF COUNCIL.

A QUARTERLY meeting of the Council was held on Oct. 12th, Sir HENRY T. BUTLIN, the President, being in the chair.

The best thanks of the Council were given to Mr. Alban Doran for his valuable services in revising the catalogue of gynæcological specimens in the Museum, and it was resolved that an illustrated guide to the gynæcological section of the Museum, prepared by Mr. Doran, be printed.

Sir FREDERIC S. EVE, on behalf of the Committee of the Annual Report of the Council, submitted a draft copy of the report to be presented to the Fellows and Members at the annual meeting on Nov. 16th, and the report was approved and adopted.

Sir W. Watson Cheyne was re-elected a member of the Committee of Management.

The PRESIDENT reported that he had reappointed Mr. C. W. Mansell Moullin the representative of the College on the Medical Board of the University of Wales for three years.

ANNUAL REPORT OF THE COUNCIL.

The Council have issued their annual report, which is to be presented at the meeting of Fellows and Members on Nov. 16th. With reference to the resolution which was passed at the last annual meeting regarding the admission of Members to direct representation on the Council, the report states that as the matter referred to in the resolution was fully considered by the Council during the year they were not prepared to reopen the discussion.

With regard to a letter from the Registrar-General asking the opinion of the College as to "whether a surgeon, in signing a death certificate, should mention the fact of an operation having been performed shortly before death," the following statement of their views has been made by the Council: (*a*) The Council are entirely in accord with the view of the Registrar-General that it is his duty to endeavour to secure the best possible certification of deaths; and they are of opinion that in every case in which an operation has been performed medical practitioners should be recommended to mention the operation in their certificates of the cause of death. (*b*) The Council are of opinion that, under the "Suggestions for Medical Practitioners" in the printed books of medical certificates forms, a general direction should be inserted to the effect that, in all cases where an operation is known to have been performed which has any reference direct, or only indirect, with the cause of death, the fact should be mentioned in the certificate of death. (*c*) The Council are of opinion that ample provision already exists for the protection of the public as regards coroners' inquests, and the Council do not consider that registrars should be instructed to inform the coroners of all cases in which an operation is mentioned in a death certificate.

The report states that the scales of medicines and medical stores issued by the Board of Trade for merchant ships are being revised, and that the revision has been entrusted by the Board to a committee consisting of members of their medical staff and representatives of the Royal Colleges of Physicians and Surgeons and Pharmaceutical Society of Great Britain, with the addition of a representative of the shipping interests concerned. Mr. C. T. Dent has been appointed to serve on the committee as the representative of the Royal College of Surgeons.

With reference to the suggested scheme for conjoint examinations with the University of London, it is stated that the Royal College of Physicians have notified the College that they were not prepared to take any further steps to promote the scheme. In consequence of this withdrawal by the Royal College of Physicians from the scheme prepared by the delegates of the two Colleges, and approved by the Council of the Royal College of Surgeons in March, 1910, it became necessary to abandon the idea of offering evidence jointly with the Royal College of Physicians to the Royal Commission on University Education in London, and to consider whether any, and, if so, what, evidence should be offered by the Royal College of Surgeons on its own account. After several suggestions had been made and considered the following resolution was finally adopted: "That, as it has been found to be impossible to proceed with the suggestion by this College for combined examinations for medical degrees by the Royal Colleges and the University, the Council do not lay any detailed proposals before the Royal Commission, but instruct their delegates, besides stating their individual views, to point out the disability under which London medical students are placed owing to the difficulty of obtaining degrees in the Medical Faculty of the University—a difficulty not experienced in other parts of the United Kingdom; the action taken by this College in the past with the object of removing this disability; and its continued willingness to coöperate in any scheme for making the degrees in the Faculty of Medicine more accessible to London medical students." The delegates appointed to give evidence on behalf of the College are Sir Henry T. Butlin, Bart. (President), Sir Henry Morris, Bart., and Sir Alfred Pearce Gould, K.C.V.O.

The National Insurance Bill, so far as its provisions concern the medical profession, has been considered by a committee of the Council appointed for the purpose, and at two special meetings of the Council; and a letter was transmitted to the Chancellor of the Exchequer by the Council directing his attention to certain matters which are regarded as of the utmost importance by members of the medical profession. The letter is contained in the report, together with the reply of the Chancellor.

Some alterations have been made in the regulations for candidates for the diplomas of M.R.C.S. and L.R.C.P., with a view to securing more thorough instruction in pathology. All candidates who pass the examination in anatomy and physiology after Jan. 1st next will be required to produce evidence of having attended at a recognised medical school a course of lectures on pathology during not less than six months, instead of during not less than three months, and of having received "practical instruction in pathological histology, including not less than eighteen classes," and "practical instruction in clinical pathology and bacteriology, including not less than eighteen classes."

For some time past classes for dissections have been held at several of the medical schools in the vacation months of April and September, and a modification has now been made in the regulations for the Fellowship to meet these conditions. The requirement that the candidate must produce evidence "of having dissected at a recognised medical school or schools for a period of not less than eighteen months during the ordinary sessions or terms" has been altered by the omission of the words "during the ordinary sessions or terms," and by the addition of the following note: "Dissections during the regular vacations will be accepted, provided the certificate shows that they have been performed under the superintendence of an authorised teacher in a medical school."

On the recommendation of the Board of Examiners in Dental Surgery an alteration has been made in the regulations for the licence to enable candidates, if they desire, to take separately mechanical dentistry and dental metallurgy, the two parts of the First Professional Examination. Acting in conjunction with the Royal College of Physicians, the Council have decided to institute a conjoint Diploma in Tropical Medicine, and regulations have been drawn up and approved by both Colleges. Examiners have been appointed, and the first examination will be held this month.

The income of the College for the past year amounts to £25,703—an increase of £150 on that of the previous year. The examination and diploma fees for the Membership, Fellowship, and Diploma in Public Health remain at nearly the same figure in each case, but there is an increase of £139 in the fees for the Licence in Dental Surgery. The expenditure in respect of revenue amounts to £23,481—a decrease of £251. Under general expenses of examinations a reduction of £891 is to be found in the case of the Membership, due mainly to the absence of any large expenditure for extraordinary purposes by the Conjoint Examining Board. The general working expenses of the College in Lincoln's Inn-fields show an increase of £106, the chief differences occurring under law expenses and furniture and fittings, the expenditure under the former being less and that under the latter more than in the previous year. The special expenses of the Museum aro £392 more than in the previous year. There are increases under the heads of salaries and wages, catalogues and reports, specimens and appliances, and furniture and fittings. The special expenses of the library remain at about the same figure. The extraordinary expenditure amounts to £1203, and includes sums of £405 for seven years' premium for fire insurance, of £120 for an epidiascope, and of £193 for the Hunterian Festival. There are also items for certain expenses in connexion with the building of the new Examination Hall in Queen-square which the committee have thought it desirable to write off under current expenditure.

The number of diplomas issued during the period with which the report deals is: Membership, 325; Fellowship, 59; Licence in Dental Surgery, 101; and Diploma in Public Health, 41.

The year has been one of much progress for the Museum, and the report contains many interesting details. Considerable progress has been made in revising and rearranging the specimens which illustrate the general principles of pathology. By the end of last year it became apparent that the space devoted to the display of the pathological collection was insufficient for its present needs and future growth, and that steps must be taken to provide room for the expansion of this part of the Museum. After careful consideration it was resolved to devote the floor space of Room III., at present occupied by a miscellaneous series of specimens, to the exhibition of the section of general pathology (estimated at 1100–1200 specimens), and thus set the lower gallery of that free for the growing sections of special pathology. The floor space of Room III. provides accommodation for displaying the specimens illustrating the general principles of pathology to great advantage—an advantage which may be realised in Rooms I. and II. where the floor space is occupied by the series of human anatomy. The section of general pathology, from the number and quality of its specimens, deserves the best space and the best setting that can be given it, for no other museum can show such a collection. This section includes many of Hunter's most valued preparations. By rearranging the tables in the floor space of Room I. it was possible to provide accommodation there for the four cases containing specimens showing the development of the human skeleton now in Room III., thus obtaining the double advantage of placing these specimens in their true position in the Museum and obtaining floor space for the extension of the pathological collection. To provide accommodation for the series of invertebrata it was found necessary to carry out alterations in a building at the eastern end of the Museum, usually known as the librarian's house, but which has been used for purposes of the Museum for over 30 years. In this building, which is entered from the staircase at the eastern end of Room V., there are two floors, an upper and lower, each of which is partitioned off into two small rooms. The upper was used for store purposes and the lower contained the ever-growing collection of surgical instruments and the stationary collection of vegetable specimens. Plans were prepared for the alteration of the building, and at considerable cost alterations have been made whereby the upper room will provide accommodation for the invertebrate and vegetable collections, while the lower will allow an extension of the space now available for the series of surgical instruments—a valuable and instructive collection—and also accommodation for the medico-legal collection which the Council in November, 1910, resolved to form. This scheme of alterations has been carried out during the months of July, August, and September of the present year. The need for a central and representative collection of

specimens required in medico-legal investigations has been felt by experts in England for many years. The obstetrical and gynæcological series of the pathological collection has been re-examined and re-described, and the series as now arranged contains 560 specimens, all of which have been studied and examined with great care and remounted when necessary. The collection of defective and malformed pelves has been greatly enriched by the addition of 28 specimens formerly in the possession of the Obstetrical Society of London and presented to the College during the present year by the Royal Society of Medicine. Specimens illustrating diseases and injuries of the ear are at the present time represented mainly by the historic Toynbee collection. Mr. Arthur Cheatle has generously presented his private collection of specimens illustrating this series—a most valuable gift—and the report adds, "it is hoped that Fellows and Members will present such specimens as will make this section of the Museum thoroughly representative of modern knowledge." Much progress has been made in the application of the card-form of catalogue, and descriptive cards of the preparations of human anatomy have been made and placed in the entrance hall cabinets. The number of visitors for the year was 13,342, rather more than half coming on Friday and Saturday, when the Museum is open to nurses and lady visitors. The number for the previous year was somewhat larger. Fifty-four women medical students have taken out tickets permitting them to study in the Museum on any week-day. The admission of special classes on Saturday afternoons has been continued, and altogether 75 classes were admitted, 22 being classes of teachers from the London County schools, 33 ambulance classes brought by their teachers from polytechnic, natural history, and other educational institutions. Regarding the College library, the supply of books and periodicals has been well kept up, and the work of cataloguing has made good progress. During the year the library has been open 272 days and the number of readers has been 10,627.

During the past year the death of one Honorary Fellow has been reported, together with 28 Fellows. The list of deceased Members shows a considerable increase on that of last year, but this is accounted for by the fact that in this year's list are included the names of several Members whose deaths took place in former years but have not been previously recorded in the College books.

Public Health.

REPORTS OF SCHOOL MEDICAL OFFICERS.

City of Bradford.—Dr. A. Lewis Williams's report contains plans of a school for cripple and deaf children of thoroughly modern plan. The more prominent features are the ample provision for ventilation, the amount of lighting area, and the facilities for teaching in the open air. The windows are sash windows and can be lowered into a recess at the bottom of the frame, thus giving the whole space for ventilation; diagrams of these windows are given in the report. A table gives a comparison of general conditions found at medical inspection for the three years 1908, 1909, and 1910, and in every case there has been a very decided improvement. A larger percentage of the children look healthier and fewer are described as anæmic. Good nutrition has risen from 24·4 per cent. in 1907 to about 70 per cent. in 1910. Probably this is to be ascribed to the provision of school meals, the Bradford scheme for which is so well known. Another interesting point about the table is that it shows that the parents are taking more interest in their families, the children being better clothed and shod. Improvement in cleanliness is ascribed to some extent to the facilities for bathing, but conditions of the heads must be placed to the credit of the parents. The number of cases of verminous heads found is now very small. Dr. Williams regrets that, owing to the time absorbed in inspection necessary to comply with the Board of Education's requirements, certain other work of the utmost value and importance has had to be curtailed, such work as that of the re-examination of children found to have some defect, examination of special cases referred by head teachers, visits to special schools for the mentally defective, blind, and deaf, occasional visits to secondary schools, examination of children who have been accidentally hurt, and examination of girls in secondary schools *re* gymnasium exercises. Dealing with nutrition, Dr. Williams classifies 1·5 per cent. boys and 2 per cent. girls as poor and very poor nutrition, but classifies 19 per cent. boys and 17 per cent. girls as anæmic and pale, this latter figure corresponding somewhat closely with the 22·5 per cent. boys and 22 per cent. girls responsible for the normal class in nutrition. The conditions treated in the School Clinic remain as in previous years—namely, defective vision, ringworm, running ears, chronic inflammation of the eyes and eyelids, scabies, impetigo, and verminous and sore heads. In October, 1910, a full-time dentist was appointed and will inspect and treat such cases as he considers suitable. Dental inspection will be carried out in the children aged from five to eight years, as during this time the permanent teeth are appearing, and by prompt attention may be saved if they are decayed. The children so inspected will be re-inspected once every subsequent year, and further treatment carried out if required. The whole group of children inspected this year and in subsequent years will therefore be made and kept dentally sound and leave school with good teeth. The treatment at the clinic consists of extracting septic teeth and scaling and preserving carious permanent teeth; urgent cases are dealt with at a special time; local anæsthetics will be given if needed. Another interesting addition to the clinic is the treatment of stammering children; 317 cases were discovered by a special inspection, of whom 239 were boys and 78 girls. 156 stammerers were treated at the clinic during the year, and an analysis of the conditions found ascribes 20 per cent. of all cases to imitation, 7 per cent. to shock due to fright, while diphtheria, scarlet fever, and pneumonia are responsible for 8 per cent. Treatment consists of breathing exercises and exercises to control the exit of air from the lungs and to strengthen the mouth and cheek muscles.

City of Manchester.—The medical officer's report is published as a section of the eighth annual report of the education committee, which is full of information of the greatest possible interest to school medical officers, and is also freely illustrated with photographs of schools, groups of children, and school buildings. Particularly interesting is the account of the Manchester country school, which is held ten miles from the town at Mobberley. The school was started in June, 1904, as an experiment, and has now been definitely taken over by the corporation. A special feature of the school is that a class of 40 children are transferred for a period of 14 days from the town school to the country school at Mobberley (regular school instructions on a modified scheme being given under the surroundings of rural life), half-time in school and half-days for walks, outdoor lessons in natural history, and organised games. The larger part of the cost in connexion with the school has been provided by voluntary subscription, more than half coming from the teachers of the day elementary schools in the city by means of jumble sales, concert parties, &c. The health of the children sent to the school has been excellent, and considerable improvement in weight has been noted. A plan is given showing the elevation of the school, and a photograph of the spray baths. The entire site covers 18 acres and the school gives accommodation for 320 children. The children are in residence during the fortnight and have to pay a sum calculated to cover the cost; with 4000 children a year it is estimated that the school will be self-supporting. Dr. A. Brown Ritchie refers to the requirements of the Board of Education, and points out that the attempt to do the inspection required has led to some of the other work getting behind. Special attention to ringworm was paid during the year, and many more cases than were suspected have been discovered, of which this report says that only about half are under control. Two interesting special reports are provided—one makes a comparison of the physique of Jewish children and other children, and one deals with the conditions associated with backwardness in children. It appears that while Jewish children have the advantage over other Manchester children as regards both height and weight (and at 13 years a Jewish boy is 5·56 lb. heavier than the others), in no case do they reach the anthropometric standard of 1883. Bad vision is very prevalent amongst Jewish boys; this probably may be put down to the fact that the Jewish boys spend on an average 2½ hours each day acquiring the Hebrew language at a private school in addition to ordinary school work. No Jewish children are returned as having bad nutrition, and only 0·4 per cent. as having rickets and deformities, as against 2·5 per cent. for others. "To sum up," the report says, "Jewish children have the advantage in height, weight, mental capacity, nutrition, diseases of the heart and blood, bronchitis, nervous diseases, tuberculosis other than lung trouble, rickets, deformities, and teeth; but they suffer more from bad vision, phthisis, enlarged tonsils, and adenoids." The advantages are ascribed to the conditions of the Jewish home life. Backward children are divided in two groups: (1) backward on account of mental condition; and (2) those backward from physical defect or from some temporary circumstances. It is suggested that these children could be best dealt with by special classes at the ordinary schools to which children from adjoining schools could be drafted.

This would not interfere with the ordinary work or with the ordinary routine of the school life, and such a plan as this would make intermediate schools unnecessary.

County of Bedford.—The chief difficulty in Bedfordshire is that experienced in following up cases and in their treatment. The comparative table of conditions in urban and rural districts is interesting. Mr. W. J. Butcher classifies 25·1 per cent. boys in urban areas as being of bad nutrition and 21·8 per cent. boys in rural districts. Attention has been called to nutrition percentages in other reports, and the very wide divergencies make it plain that no uniform standard is being used. Mr. Butcher, in an addendum to the report, goes into the question of treatment, and makes the suggestion that the education authority should spend £100 a year on the treatment of the most urgent vision cases, and in subscription to the local hospitals in exchange for letters which would enable at least the most urgent cases of enlarged tonsils and adenoids to be treated. The formation of care committees is also considered, with lady visitors to visit the homes and also school nurses. No school nurse has as yet been appointed, and it is to be hoped that Mr. Butcher's very modest scheme will be duly sanctioned.

County of East Sussex.—Mr. A. G. R. Foulerton considers that enlarged tonsils and adenoids cause more ill-health in East Sussex than any other single disease or defect. Some very marked cases are noted in his report. Out of 273 children for whom operative treatment was recommended in 1909 51 per cent. obtained treatment within six months. Out of 346 children in 1910 35 per cent. received treatment. The schools are revisited after inspection at an interval of two to four months, and of 1372 children noted for treatment in 1910 50·22 per cent. obtained it, the corresponding figures for 1909 being 1353 and 49·8 per cent. Coöperation with the local sanitary authorities has usually been effective. But two cases are quoted of apparently capricious closure of a school on account of an outbreak of infectious illness which appeared to be already over when closure was required. There is also an instance where closure for three weeks by advice of the county medical officer for diphtheria (the school not having been visited by the local authorities concerned) was followed by an order for another closure of three weeks given four days before the school would normally have reopened on account of a drainage defect which could have been discovered and dealt with earlier had the premises been visited earlier. These disorders of coöperation appear to be due to the unwieldy overgrowth of the local sanitary area concerned. Dr. Arthur Beeley presents two special reports on (1) Dental Caries and (2) on the Relation of Enlargement of Glands of Neck with Enlargement of Tonsils, Caries of Teeth, and Impairment of Nutrition Respectively. Tables displaying the relation of these various factors are given, but would have been more valuable if greater help had been given in their interpretation.

County of Salop.—Dr. James Wheatley's report pays considerable attention to dental caries, rules for the prevention of which are formulated and have been circulated among the medical practitioners in the county. Voluntary helpers have been appointed in 190 schools out of 279 to assist in obtaining treatment. About half the children with defects appear to have been treated, more than half by private practitioners.

County Borough of Halifax.—Dr. D. M. Taylor has made special efforts to enlist the sympathetic coöperation of parents. Evening addresses have been given at some schools on personal, school, and home hygiene. Visitors' or exhibition day is condemned reluctantly. The clinic held at the medical offices treats the usual school ailments. A successful class for the treatment of stammerers has been held, the Berquand method being used; out of 22 children 18 were cured, two improved, and two remained as before.

DONATIONS AND BEQUESTS.—By the will of the late Dr. F. W. Pavy, Guy's Hospital will receive £2000 for the maintenance and upkeep of the "Pavy Gymnasium," founded by him. The testator also left £1000 to the British Medical Benevolent Fund.—His Highness Sir Chandra Shum Shere Jung has sent a donation of £1000 towards the new laboratory extension fund at the Brompton Hospital for Consumption and Diseases of the Chest.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 77 of the largest English towns, having an estimated population of 16,157,797 persons in the middle of this year, 7671 births and 4633 deaths were registered during the week ending Oct. 14th. The annual rate of mortality in these towns, which had steadily decreased from 21·2 to 15·2 in the seven preceding weeks, further declined to 15·0 per 1000 in the week under notice, and was 1·6 per 1000 below the mean annual rate recorded during the third quarter of the present year. In London last week the death-rate was equal to 15·4 per 1000, while the recorded rates in the other large towns ranged from 6·5 in Burton-on-Trent, 6·8 in Handsworth (Staffs.), 7·0 in King's Norton, and 8·3 in Walthamstow to 19·5 in Dewsbury, 19·6 in Bury, in Hull, and in Sunderland, and 23·3 in Oldham. The 4633 deaths from all causes in the 77 towns last week were 74 less than the number returned in the previous week, and included 512 which were referred to the principal epidemic diseases, against numbers decreasing from 2900 to 802 in the seven preceding weeks. Of these 512 deaths, 357 resulted from infantile diarrhœa, 44 from diphtheria, 39 from enteric fever, 35 from whooping-cough, 27 from measles, and 10 from scarlet fever, but not one from small-pox. The mean annual death-rate from these epidemic diseases last week was equal to 1·7 per 1000 against 3·4 and 2·6 in the two preceding weeks. The deaths of infants under 2 years of age attributed to diarrhœa, which had steadily decreased from 2714 to 628 in the seven preceding weeks, further declined to 357 last week, and caused the highest annual death-rates of 2·7 in Swansea, 3·3 in West Hartlepool, 3·4 in Burnley, and 3·5 in Wigan. The deaths referred to diphtheria, which had been 46 in each of the two preceding weeks, were 44 last week, and included 13 in London and its suburban districts, 4 in Liverpool, 3 in Norwich, and 3 in Hull. The fatal cases of enteric fever, which had been 35 and 37 in the two preceding weeks, further rose last week to 39; 6 deaths were recorded in St. Helens, 5 in Hull, and 3 each in London, Nottingham, Bradford, and Leeds. The deaths attributed to whooping-cough, which had been 61, 51, and 55 in the three preceding weeks, fell to 35 last week, and included 5 in London, 5 in Sunderland, and 2 each in St. Helens, Leeds, and Stockton-on-Tees. The deaths referred to measles, which had been 26, 19, and 18 in the three preceding weeks, rose to 27 last week; 7 deaths were registered in Wolverhampton, 4 in London, 4 in Liverpool, and 2 in Burnley. The 10 fatal cases of scarlet fever were 8 fewer than in the previous week, and was the lowest number returned in any week of the current year; 4 deaths occurred in London and 2 in Salford. The number of scarlet fever patients under treatment in the Metropolitan Asylums and in the London Fever Hospital, which had steadily increased from 1327 to 1793 in the six preceding weeks, had further advanced to 1966 on Saturday last; 355 new cases of this disease were admitted to these hospitals during the week, against 240, 333, and 293 in the three preceding weeks. These hospitals also contained on Saturday last 1030 cases of diphtheria, 209 of whooping-cough, 178 of enteric fever, and 82 of measles, but not one of small-pox. The 1335 deaths from all causes in London last week were 34 in excess of the number in the previous week, and included 210 which were referred to diseases of the respiratory system, against numbers steadily increasing from 73 to 172 in the six preceding weeks. The deaths attributed to different forms of violence in the 77 towns, which had been 134 and 156 in the two preceding weeks, further rose to 170 last week, and 369 inquest cases were registered. The causes of 43, or 0·9 per cent., of the deaths registered in the 77 towns during the week under notice were not certified either by a registered medical practitioner or by a coroner after inquest. All the causes of death were duly certified last week in Manchester, Sheffield, Bristol, West Ham, Bradford, Hull, Newcastle-on-Tyne, Portsmouth, and in 50 other smaller towns. The 43 uncertified causes of death last week included 11 in Liverpool, 7 in Birmingham, and 3 in South Shields.

HEALTH OF SCOTCH TOWNS.

In eight of the principal Scotch towns, having an estimated

population of 1,710,291 persons in the middle of this year, 829 births and 538 deaths were registered during the week ending Oct. 14th. The annual rate of mortality in these towns, which had been 16·7, 15·2, and 14·9 per 1000 in the three preceding weeks, rose to 16·4 in the week under notice. During the 13 weeks of the third quarter of this year the annual death-rate in these towns averaged 15·2 per 1000, and was 1·4 per 1000 below the mean rate recorded during the same period in the 77 large English towns. The annual death-rates in the Scotch towns last week ranged from 10·2 and 11·2 in Perth and in Aberdeen to 16·1 in Dundee and 18·7 in Glasgow. The 538 deaths from all causes in the eight towns were 48 in excess of the number in the previous week, and included 74 which were referred to the principal epidemic diseases, against numbers decreasing from 134 to 60 in the six preceding weeks; of these 74 deaths, 41 resulted from diarrhœa, 12 from diphtheria, 8 from scarlet fever, 7 from whooping-cough, 5 from measles, and 1 from enteric fever, but not one from small-pox. The mean annual death-rate from these epidemic diseases in the eight towns last week was equal to 2·3 per 1000, and was 0·6 above the mean death-rate from the same diseases in the 77 large English towns. The deaths attributed to diarrhœal diseases, which had steadily fallen from 113 to 33 in the six preceding weeks, rose to 41 last week, and included 37 of infants under two years of age; 24 deaths were recorded in Glasgow, 7 in Dundee, and 4 in Edinburgh. The deaths referred to diphtheria numbered 12, and were equal to the average in the two preceding weeks; 8 deaths occurred in Glasgow and 2 in Dundee. The fatal cases of scarlet fever, which had been 5, 3, and 8 in the three preceding weeks, were again 8 last week, and comprised 5 in Glasgow, 2 in Paisley, and 1 in Dundee. The deaths attributed to whooping-cough, which had declined from 12 to 3 in the three preceding weeks, rose to 7 last week, of which 6 were registered in Glasgow. The 5 fatal cases of measles were 1 in excess of the number in the previous week, and comprised 4 in Glasgow and 1 in Leith. The death from enteric fever was recorded in Glasgow. The deaths referred to diseases of the respiratory system, which had steadily risen from 41 to 78 in the four preceding weeks, further increased to 80 last week, and were 11 in excess of the number in the corresponding week of last year. Of the 538 deaths from all causes in the eight towns last week, 180, or 33 per cent., were recorded in public institutions, and 23 deaths were attributed to different forms of violence. The causes of 20, or 3·7 per cent., of the deaths in the eight towns last week were not specified or not certified; in the 77 English towns the proportion of uncertified causes last week did not exceed 0·9 per cent.

HEALTH OF IRISH TOWNS.

In the 22 town districts of Ireland, having an estimated population of 1,149,495 persons in the middle of this year, 584 births and 425 deaths were registered during the week ending Oct. 14th. The annual rate of mortality in these towns, which had been 18·0 and 19·6 per 1000 in the two preceding weeks, declined to 19·3 per 1000 in the week under notice. During the 13 weeks of the third quarter of this year the annual death-rate in these Irish towns averaged 18·3 per 1000; in the 77 English towns during the same period the mean annual death-rate was equal to 16·6, whilst in the eight Scotch towns it did not exceed 15·2 per 1000. The annual death-rate last week was equal to 21·7 in Dublin (against 15·4 in London), 15·9 in Belfast, 25·2 in Cork, 15·3 in Londonderry, 16·3 in Limerick, and 26·6 in Waterford; whilst in the 16 smallest of these Irish towns the mean annual death-rate was equal to 19·0 per 1000. The 425 deaths from all causes in the 22 Irish towns were 6 fewer than the number returned in the previous week, and included 74 which were referred to the principal epidemic diseases, against numbers decreasing from 153 to 81 in the six preceding weeks; of these 74 deaths, 58 resulted from diarrhœa, 5 from enteric fever, 5 from diphtheria, 3 from whooping-cough, 2 from scarlet fever, and 1 from measles, but not one from small-pox. These 74 deaths from the principal epidemic diseases were equal to an annual death-rate of 3·4 per 1000. The mean rate from the same diseases in the 77 English towns last week was equal to 1·7, while in the eight Scotch towns it averaged 2·3 per 1000. The deaths attributed to diarrhœal diseases, which had decreased from 121 to 71 in the four preceding weeks, further declined to 58 last week, and included 54 of infants under two years of age; 28 deaths were recorded in Dublin, 13 in Belfast, 4 in Londonderry, and 3 in Waterford. Of the 5 fatal cases of enteric fever, which were equal to the average in the two preceding weeks, 4 were registered in Dublin and 1 in Cork. The deaths referred to diphtheria numbered 5, against an average of 2 during the seven preceding weeks; 4 deaths occurred in Dublin and 1 in Belfast. The 3 deaths from whooping-cough were slightly in excess of recent weekly numbers, and comprised 2 in Belfast and 1 in Dublin The 2 fatal cases of scarlet fever occurred in Dublin and Belfast respectively, and that from measles in Dublin. The deaths referred to diseases of the respiratory system in the 22 town districts, which had been 42 and 64 in the two preceding weeks, declined to 50 last week. Of the 425 deaths from all causes in the Irish towns last week, 141, or 33 per cent., were recorded in public institutions, and 10 deaths were attributed to different forms of violence. The causes of 21, or 4·9 per cent., of the deaths registered in the 22 towns last week were not certified either by a registered medical practitioner or by a coroner after inquest; the proportion of uncertified causes in the week under notice did not exceed 0·9 per cent. in the 77 large English towns, and was equal to 3·7 per cent. in the eight Scotch towns.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

IN accordance with the provisions of Order in Council of April 1st, 1881, Fleet-Surgeon Jeremiah Sugrue has been placed on the Retired List (dated Oct. 9th, 1911).

Fleet-Surgeon William Wenmoth Pryn has been promoted to the rank of Deputy Surgeon-General in His Majesty's Fleet (dated Oct. 12th, 1911).

The undermentioned Acting Surgeons have been confirmed in the rank of Surgeon in His Majesty's fleet:—Roger Aiken Rankine, Vernon Lickfold Matthews, Adrian Charles Paterson, William Lewis Cowardin, Quintin Hume Richardson, Herbert White, and Leonard Alexander Moncrieff (dated May 19th, 1911).

The following appointments have been notified:—Staff-Surgeons: W. H. Pope to the *Sapphire*, on recommissioning; and H. J. Chater, to the *Attentive*, on commissioning. Surgeon: G. Carlisle to the *Vernon*, additional, for the *Furious*.

ROYAL ARMY MEDICAL CORPS.

Colonel F. H. Treherne, on vacating medical charge of the Cambridge Hospital at Aldershot on promotion, has embarked for a tour of service in India to take up the appointment of Administrative Medical Officer of the Allahabad Brigade. Lieutenant-Colonel (local Colonel) H. B. Matthias, Principal Medical Officer of the Egyptian Army, has arrived home on leave of absence from Khartoum. Lieutenant-Colonel H. Cocks, from the Royal Herbert Hospital at Woolwich, has taken up duty at the Military Hospital, Shorncliffe. Lieutenant-Colonel S. G. Allen, commanding the 28th Company, Royal Army Medical Corps, and in charge of the Military Hospital at Gibraltar, has arrived home on leave of absence. His Majesty the King has been graciously pleased to sanction the promotion of Surgeon-Lieutenant-Colonel Sir W. R. Crooke-Lawless, C.I.E., as a Knight of Grace in the Order of the Hospital of St. John of Jerusalem in England. Lieutenant-Colonel M. J. Sexton, at present holding medical charge of the Military Hospital at Arbor Hill, Dublin, has been placed under orders by the War Office to proceed to South Africa for a tour of service during the ensuing trooping season. Lieutenant-Colonel R. W. Wright has embarked for a tour of duty in India. Major M. P. Corkery, in medical charge of the Lawrence School and residency surgeon at Mount Abu, Bombay Command, has been granted leave of absence home from India for eight months. Major E. C. Anderson, D.S.O., from Rawal Pindi, has taken up duty at the Station Hospital, Karachi. Major P. H. Collingwood has been transferred from Exeter to Devonport. Major H. E. Staddon, from Chichester, has been appointed to the Military Hospital at Shorncliffe. Major C. A. Stone has

joined at Parkhurst Military Hospital and taken over charge from Lieutenant-Colonel J. F. Donegan, appointed Recruiting Medical Officer at Woolwich. Major F. W. Bebie, commandant of the Royal Army Medical Corps School of Instruction at Salisbury Plain, has taken up duty at the Military Hospital, Colchester, on the termination of field training. Major J. S. Gallie has been transferred to the home establishment from India. Major M. H. G. Fell, sanitary specialist at Cairo, has arrived home on leave of absence. Major T. H. J. C. Goodwin, D.S.O., at present serving at Aden, has been granted three months' general leave. Captain F. W. Dawson, attached to the Royal Infirmary, Phœnix Park, Dublin, has been placed under orders to embark for India about Nov. 10th for service with the Northern Army. Captain H. C. Hildreth, in charge of the military hospital at Glen of Imaal, has been granted leave of absence preparatory to joining the Royal Army Medical College, London, for the promotion course for captains commencing on Nov. 1st next. Captain G. Baillie, on the termination of leave granted for duty on the West Coast of Africa, has been appointed to the London District temporarily, pending embarkation. Captain E. M. Pennefather has been transferred from the Dublin District to the Cork District. Captain S. Boglan-Smith has taken up the appointment of Specialist Sanitary Officer in the Belfast District. Captain E. P. Lauder, from Aldershot, has been appointed to the Cork District. Captain W. S. Crosthwait, on relinquishing medical charge of the troops at Moore Park Camp, has been detailed for duty at Fermoy. Captain W. J. Thompson, from Lucknow, has been appointed to the station hospital at Cawnpore for duty. Captain V. C. Honeybourne has arrived home on leave of absence from India. An exchange of positions on the roster for service abroad has been sanctioned by the Director-General of the Army Medical Service between Captain A. R. Greenwood, specialist in advanced operative surgery, serving at Aldershot, and Captain H. T. Stack, doing duty at the Military Hospital, Londonderry. Lieutenant W. H. O'Riordan has joined at York from Whitley Bay. Lieutenant O. W. McSheehy, on the closing of Willsworthy Camp, has been posted to Okehampton. Lieutenant R. C. Priest, in medical charge of the staff and military families at Colchester, has been granted leave of absence from Oct. 31st to Nov. 28th next, pending embarkation for a tour of service in India.

INDIAN MEDICAL SERVICE.

Lieutenant-Colonel P. J. Lumsden, agency surgeon, Bengal Presidency, has been granted seven months' leave of absence home from India. Lieutenant-Colonel R. B. Roe has been transferred from the appointment of principal medical officer of the Allahabad Brigade to be Principal Medical Officer of Karachi Brigade. Lieutenant-Colonel C. H. Bedford, Bengal Presidency, has been granted six months' leave of absence from India by the Home Department. Lieutenant-Colonel J. R. Adie has taken up duty as Chief Medical Officer in Charge of Malarial Fever Prevention in the Punjab. Lieutenant-Colonel M. A. Ker has been transferred to the medical charge of the 2nd Gurkha Rifles in succession to Lieutenant-Colonel C. E. L. Gilbert appointed to the medical charge of the 26th Punjabis. Major A. E. Berry has been selected for appointment by H. E. the Commander-in-Chief in India as Specialist in Ophthalmology to the Fifth (Mhow) Division of the Southern Army. Major B. R. Chatterton, civil surgeon of Muzaffarpur, has arrived home on leave of absence. Major V. H. Roberts has taken up duty as District Plague Medical Officer of Rohtak District. Major R. G. Turner, civil surgeon of Gonda, has been granted privilege leave combined with furlough up to Jan. 14th next. H. E. the Governor of Bombay in Council has been pleased to appoint Major S. C. Evans to be Professor of Midwifery at the Grant Medical College, Bombay, and to hold medical charge of the Bai Motlibai and Sir D. M. Petit Hospitals. Captain G. A. Jolly has been appointed to officiate as Civil Surgeon of Mainpuri. The services of Captain R. T. Wells have been placed at the disposal of the Home Department. Captain C. A. Sprawson has been granted an extension of his leave of absence by the Secretary of State for India. Captain F. P. Mackie has been selected to officiate as Civil Surgeon of Bijnor. The services of Captain E. P. Mackie have been placed at the disposal of the Home Department. H.E. the Commander-in-Chief in India has appointed Captain G. C. L. Kerans to be Specialist in Ophthalmology to the Eighth (Lucknow) Division. Captain C. A. Gourlay, civil surgeon of Kamrup, has been permitted leave of absence home from India for 18 months. Captain W. S. Nealor has been appointed Civil Surgeon of Ahmednagar in succession to Captain A. Murphy. Captain C. J. Brierley, Bengal Presidency, has been granted six months' extension of his leave of absence by the Secretary of State for India. Major W. S. Willmore, civil surgeon of Mirzapur, has been deputed to the Central Research Institute at Kasauli for a course of instruction in clinical bacteriology. The services of Captain J. H. Horton, D.S.O., have been placed temporarily at the disposal of the Government of Bombay. Captain J. G. G. Swan, Bengal Presidency, has returned to India on the expiration of his leave of absence. Lieutenant E. H. V. Hodge has been appointed to the officiating Medical Charge of the 26th Punjabis.

TERRITORIAL FORCE.

Royal Army Medical Corps.

Eastern Mounted Brigade Field Ambulance: Lieutenant Oliver Smithson resigns his commission (dated Oct. 11th, 1911).

5th London Field Ambulance: John Pomeroy Grainger to be Lieutenant (dated Sept. 23rd, 1911).

3rd North Midland Field Ambulance: Major Howard H. C. Dent to be Lieutenant-Colonel (dated Sept. 5th, 1911).

1st Welsh Field Ambulance: Lieutenant John O'Sullivan to be Captain (dated June 19th, 1911).

Attached to Units other than Medical Units.—Captain George H. Goldsmith resigns his commission (dated Oct. 11th, 1911).

For attachment to Units other than Medical Units.—Surgeon-Captain William Reginald Eyton Williams, from the 4th Battalion, The Welsh Regiment, to be Captain (dated Oct. 11th, 1911).

THE TERRITORIAL DECORATION.

The King has conferred the Territorial Decoration upon the undermentioned officers of the Territorial Force:—

Royal Army Medical Corps.—Lieutenant-Colonel Archibald Kerr Chalmers, Sanitary Officer of the Lowland Territorial Division; Major Robert Rannie, attached to the 7th (Deeside Highland) Battalion, The Gordon Highlanders; Major Walter Alexander Atkinson, attached to the 21st (County of London) Battalion, The London Regiment (First Surrey Rifles); Major Walter Moffett Hamilton, attached to the 7th Battalion, The Lancashire Fusiliers; Major Charles Thomas Griffiths (Retired List); Captain Robert Thomson Ferguson (Retired List).

VOLUNTEER OFFICERS' DECORATION.

The King has conferred the Volunteer Officers' Decoration upon the undermentioned officer of the Territorial Force who has been duly recommended for the same under the terms of the Royal Warrant, dated July 25th, 1892:—

Royal Army Medical Corps.—Lieutenant-Colonel G. Sims Woodhead, Sanitary Service.

PRIZE DISTRIBUTION AT HASLAR HOSPITAL.

The course of instruction of the newly entered Acting Surgeons at Haslar was brought to a close on Oct. 10th. The prizes were distributed by Admiral Sir Arthur W. Moore, Commander-in-Chief. The gold medal was gained by Acting Surgeon V. L. Matthews of the London Hospital. The silver medal was awarded to Acting Surgeon R. A. Rankine of Guy's Hospital. Three Navy Regulation Pocket-cases—prizes for subjects in which instruction is given at Haslar—were awarded to Acting Surgeons R. A. Rankine, V. L. Matthews, and W. L. Cowardin. The following list shows the places gained by the combined marks of the London and Haslar examinations:—

		Marks.
Acting Surgeon	V. L. Matthews...	3716
,,	R. A. Rankine	3660
,,	Q. H. Richardson	3306
,,	W. L. Cowardin	3263
,,	H. White	3222
,,	L. A. Moncrieff...	3207
,,	A. C. Paterson	3154

The above gentlemen have now been confirmed in the rank of Surgeon, as stated in a foregoing paragraph.

HEALTH OF THE NAVY.

The annual report of the health of the Navy for 1910 has

just been issued as a Parliamentary paper. We hope in an early issue of THE LANCET to deal fully with this report, which shows a continuous improvement in the general health of the fleet as compared with the preceding five years.

THE NAVAL MEDICAL SUPPLEMENTAL FUND.

At the quarterly meeting of the directors of the Naval Medical Supplemental Fund, held on Oct. 10th, Sir W. Graham Greene, K.C.B., in the chair, the sum of £40 was distributed among the several applicants.

A complimentary dinner was given on Oct. 11th at the Grand Hotel, Trafalgar-square, London, to Captain F. M. Parry, R.A.M.C., late Adjutant Royal Army Medical Corps School of Instruction, Home Counties Division, by the officers of Territorial Royal Army Medical Corps Units in the Division. The chair was occupied by Colonel J. Turton, V.D.

Correspondence.

"Audi alteram partem."

THE ELECTION OF DIRECT REPRESENTATIVES ON THE GENERAL MEDICAL COUNCIL.

To the Editor of THE LANCET.

SIR,—Having after more than 35 years' residence in London as a general practitioner found it necessary to seek more healthful climatic conditions in my native county I had hoped to retire from public work, but in view of the Government Insurance Bill which so grossly attacks the rights and interests of general practitioners I have decided, at the request of numerous medical friends and supporters at former elections, to again offer myself as a candidate for a seat on the General Medical Council.

Another reason which has influenced me to accept nomination is that I think it most important to enter a protest against the attempt of the executive of the Association to capture all the seats reserved for Direct Representatives for England and Wales. If the Council and officials are permitted to use the financial and other resources of the Association in furthering the election of their nominees and to defeat other well-known members of the Association who for many years have borne the burden and heat of the day in the cause of medical reform—as was done at the last election, when my friend and former colleague on the General Medical Council, Mr. George Jackson, was defeated in his attempt to regain the seat he had so ably filled for five years—the independent candidate will be crushed out, freedom of choice on the part of the electors will no longer exist, and Direct Representation will be reduced to a silly burlesque.

I hope to have an early opportunity of presenting my views on current medical politics before the electors. Meantime I thank you in anticipation for your courtesy in publishing this communication.

I am, Sir, yours faithfully,
GEORGE BROWN,
Late Direct Representative for England and Wales on the General Medical Council.
Callington, Cornwall, Oct. 16th, 1911.

To the Editor of THE LANCET.

SIR,—As I have so recently been a candidate for election as a Direct Representative, when I polled within 200 votes of the successful candidate, I feel that any lengthy address is unnecessary now.

Having previously served on the Council from 1902 to 1907 I am thoroughly acquainted with the duties of the office, during which time I was a member of various important committees. One of the most important in my opinion amongst many matters requiring attention is that more stringent regulations should be adopted with regard to unqualified practice and quacks generally.

Any Act of Parliament which may be passed should contain a clause forbidding any colourable pretence being made of being a physician or surgeon. The necessity of some tangible return to the principle of modified pupillage is one which I have formerly urged on the Council, and should do so again. The necessity of more time being given to the purely professional side of the students' studies by allowing the scientific subjects to be taken elsewhere before entrance at the medical schools is an urgent one.

Having been the representative of my division (Plymouth) since the commencement of the representative meetings, I am well acquainted with the views of the British Medical Association with regard to the State Insurance Bill, and shall be prepared to support them if elected to the General Medical Council.

I am, Sir, yours faithfully,
GEORGE JACKSON, F.R.C.S. Eng.,
Late President, now Vice-President, South-Western Branch B.M. Association, Late Member of Medico-Political and other Central Committees of the Association.
Plymouth, Oct. 16th, 1911.

To the Editor of THE LANCET.

SIR,—With your permission, and in answer to several letters and inquiries I have received, I should like to state, through the medium of your columns, that I shall again be a candidate for one of the vacant seats on the General Medical Council.

I think the profession should have the opportunity of expressing its agreement or otherwise with the attempt which is now being made by the British Medical Association to monopolise the direct representation for those favoured by the council of the Association. I think the general body of members of the Association cannot quite realise the unfairness of the scheme under which their three candidates are now being put forward, and if the profession is foolish enough to ratify this scheme by returning the Association nominees, direct representation in England and Wales will be nothing less than a mockery.

I am, Sir, yours faithfully,
Leeds, Oct. 16th, 1911. ARTHUR HAWKYARD.

To the Editor of THE LANCET.

SIR,—I am joining Dr. George Brown and Dr. Hawkyard as candidates for the three vacancies on the General Medical Council. Our address will be published next week.

I am, Sir, yours faithfully,
Lower Edmonton, Oct. 18th, 1911. SIDNEY C. LAWRENCE.

CONDITIONS OF PRACTICE IN SOUTH AMERICA.

To the Editor of THE LANCET.

SIR,—In the issue of THE LANCET of August 26th, p. 657, appears an article on the conditions of medical practice in various countries of the world. In dealing with practice in the Argentine Republic the writer states that an examination in the Spanish language must be passed, and certain fees paid, before a foreign doctor is entitled to practise. This statement is certainly true, but is hardly calculated to give an accurate idea of conditions of practice in this country.

A foreign medical man is required to take the same course as the Argentine medical student, and as this course occupies seven years and includes some 30 examination it is not an undertaking which can be lightly embarked upon. It is true that a foreign practitioner is permitted to compress his examinations into a shorter period than seven years, but he cannot obtain exemption from any of the examinations. So many medical men have come out to this country under the impression that they can obtain permission to practise their profession without much difficulty that I think it advisable to make this statement of the true condition of affairs. Especially do I think this to be advisable after reading the somewhat incomplete statement in the article referred to.

Under the heading of "Brazil, South America," it is stated that in this country "the consent of the faculty of medicine and pharmacy must be obtained and certain small fees paid" before practice is permitted. This does not create a true impression of the state of affairs in that country. I understand from information obtained from medical men practising in Brazil that the difficulties put in the way of foreign practice are, if anything, greater than those existent in the Argentine. During the last few years very few foreign medical men have succeeded in establishing themselves in Brazil, and every discouragement is offered to those who attempt to do so.

The large number of qualified medical men turned out by the Universities of Rio de Janeiro and of Buenos Aires will not tend in the future to the lowering of demands made upon foreign doctors settling in South America. Although British medical men will always be courteously received, at any rate at the University of Buenos Aires, the demands made upon them will probably be even more exacting in the future than they are at the present moment. The Argentine Faculty of Medicine has learned the necessity of preventing the excessive immigration of foreign doctors, and one can hardly complain of the measure it has adopted in order to protect its own native practitioners.

I am, Sir, yours faithfully,

K. MACFARLANE WALKER, F.R.C.S. Eng.

Buenos Aires, Sept. 18th, 1911.

ANOTHER WAY OF DEALING WITH DEGENERATES.

To the Editor of THE LANCET.

SIR,—Will you allow me to offer for the consideration of your readers a few facts in support of my assertion, which Dr. Ewart has done me the honour to quote, that weakness of will, in proper circumstances, makes for morality and happiness. It is now about 13 years since I first began to call attention on every occasion to the evil we were permitting in leaving the feeble-minded at large and at liberty to propagate their species. I have tried to show that our very tenderness for the weak and suffering has, by its interference with the laws of natural selection, increased this evil, since we are keeping alive all weaklings whom by any means we can keep alive. At the same time I was anxious to show that there were legitimate and practical methods of dealing with the feeble-minded. Our colony at Sandlebridge has succeeded, not beyond our hopes, but beyond the expectation of those who have watched our experiment. Building on the weakness of will which is common to all feeble-minded people we laid our plans accordingly; we said that we would admit only children under the age of 13, and that we would make them so happy, we would so train them, that they should never leave us. The feeble-minded have, as a rule, no ideas except those that are suggested to them; we have suggested to them unceasingly the idea that they are at home and that if they will behave themselves they shall never be turned out. For the results we have now in our colony 232 boys and girls. These are what remain out of 284 admitted during ten years. Of the 52 not now with us, some were probation cases and were discharged after a few weeks' residence as too idiotic or too severely invalided to be suitable cases for us; a few have become insane and have been transferred to asylums; 6 have died; the remainder, 13 in number, represent our failures; they are young men and women who have been persuaded by bad parents to leave us after they had been trained. A very slight alteration in the law would give us powers to withstand such parents as these. Of those now with us, 74 are between the ages of 16 and 23. Of course, more of them are young men than young women; there are so many more boys than girls of this type. They are still simple, good children; subject, as are all children, to outbreaks of temper at times, but generally proving, by their behaviour and their contented happiness, that our method of dealing with them is, in itself, quite sufficient and efficient. We have an able doctor who looks after their health; we pay great attention to their diet and to all points of behaviour and manners. Our lads are engaged in farm and garden work; or they are busy with the carpenter or the plumber; or they are trained to be house-boys, and to do in the boys' houses what the girls do in the girls' houses. Our girls are busied with sewing, knitting, house and laundry work. From the moment we take them into the school for little children, we keep in view three essential considerations: our children must be good and happy; they must be permanently detained that they may never themselves have children; they must be so trained as to reach their greatest possible industrial value. I think anyone who will take the trouble personally to consider our work will realise that we are achieving our aims. I think it would also be admitted, by anyone visiting us, that no other means are necessary for the safeguarding of the national health than an extension of those we have adopted.

I am, Sir, yours faithfully,

Manchester, Oct. 11th, 1911. MARY DENDY.

THE RELATION OF THE ORGANIC PHOSPHORUS CONTENT OF VARIOUS DIETS TO DISEASES OF NUTRITION, PARTICULARLY BERI-BERI.

To the Editor of THE LANCET.

SIR,—In an annotation with the above title contained in your issue of the 14th inst. it is stated that "the disease, as it occurs in the Far East, is now generally recognised to be due to a dietary of white rice from which the pericarp of the grain has been removed in the process of 'polishing' or milling (the pericarp containing the bulk of the phosphates and other salts)." I venture to think that this statement requires modification, for it can only be explained on the assumption that the writer is not acquainted with the published works on "The Etiology of Beri-beri," by Dr. A. T. Stanton and myself, and with the botanical structure of the fruit (a caryopsis) of the rice plant. Eijkman originally stated that removal of the pericarp from the rice-grain rendered the product harmful, and believed that the pericarp contained an antidote to a poison contained in the grain. Schaumann copied this statement so far as the pericarp is concerned, but believed that its removal deprived the grain of organic phosphorus compounds. Simpson and Edie have copied Schaumann's statement, hence its appearance in THE LANCET.

The pericarp is a thin, cellular, protective structure, the removal of which does not in any way impair the nutritive value of the grain, and the pericarp does not contain the bulk of the phosphates and other salts. Parboiled rice which has been "pearled" once is free from pericarp, and, cooked in the ordinary way, can never produce beri-beri. The layers subjacent to the pericarp (the sub-pericarpal layers) are the important ones, and it is the retention of these layers which is essential for the prevention of beri-beri among peoples whose staple of diet is rice.

The plates published in 1911 in the report, entitled "The Etiology of Beri-beri" (No. 12 of the Studies from the Institute for Medical Research, Kuala Lumpur, F.M.S.), and which were drawn from actual sections, show clearly the retention of the important subpericarpal layers in an unpolished (harmless) rice and their absence from a polished (harmful) rice. In addition, the plates show that the contents of the cells in the subpericarpal layers differ from those of the other cells of the endosperm.

In direct proportion to the extent to which the subpericarpal layers are removed in the process of polishing is the phosphorus-content of the grain diminished, and so likewise is the content in respect of other substances, such as proteins, fats, and salts. The phosphorus-content serves, therefore, as an indicator of the extent to which rice has been polished, and this is all we have ever claimed for it. The quantitative estimation of any of the other constituents of the grain might serve this purpose equally well, but estimations of proteins, fats, and ash would not be satisfactory for reasons stated in our report.

The beri-beri producing power of a rice when consumed as the staple of diet is in inverse proportion to its phosphorus-content and in direct proportion to the extent to which it has been polished, but there is no evidence to show that white rice is harmful because of a diminished phosphorus-content. On p. 56 of "The Etiology of Beri-beri" we mention the case of a parboiled rice which after extraction with 94 per cent. alcohol was proved harmful; the phosphorus-content of this rice before and after extraction differed only to an extent compatible with the range of experimental error. The other experimental evidence, which we have stated in detail, proves that a deficiency of organic phosphorus compounds is not the cause of beri-beri.

We have dealt at length with some of the errors into which Dr. Schaumann has fallen; he has certainly produced no evidence, experimental or otherwise, to justify his conclusion that tropical beri-beri is due to deficiency of organic phosphorus compounds in the diet. Dr. Simpson and Mr. Edie have translated and abstracted Dr. Schaumann's book; their own experiments add nothing new to our knowledge of the subject.

The present problem is one for solution by a physiological chemist who shall isolate and identify the substance of high physiological importance contained in the subpericarpal layers. He will find a substance, which

is not a protein, which will not contain phosphorus, and the presence of which in extremely small amounts is necessary for the prevention of beri-beri. The etiology of other diseases may or may not be explained on a basis similar to that which explains the etiology of beri-beri, but in the present state of our knowledge wide-sweeping statements such as have been made are to be deprecated. Certain facts have been determined; apply these facts and true or tropical beri-beri must cease to exist. Other facts can now be determined, and until that work has been accomplished no conclusions other than those we have arrived at are possible or permissible. I am, Sir, yours faithfully,

H. FRASER,
Director, Institute for Medical Research,
Oct. 16th, 1911. Kuala Lumpur, F.M.S.

THE NATIONAL INSURANCE BILL.

To the Editor of THE LANCET.

SIR,—In the letter of your correspondent, Mr. Albert Benthall, there occurs this passage: "The suggestion of payment by fee for each attendance is a delightful dream, but purely Utopian and out of the range of practical politics, as it would land the Insurance Fund in bankruptcy in the first year." I would earnestly ask the profession to consider what this means. It is that the Bill does not provide money enough to pay medical men for the work it imposes upon them. The "magnificence" of this Bill would appear to consist in vicarious charity at the expense of the medical profession. I am, Sir, yours faithfully,

ALFRED E. A. LOOSELY.
New Cavendish-street, W., Oct. 15th, 1911.

To the Editor of THE LANCET.

SIR,—The question cropped up at a meeting of our medical society, viz., in the event of the Insurance Bill passing into law how much are we as practitioners going to charge for attendance on wife and family? A suggestion was put forward that 5*s*. per member per annum was a reasonable figure. What do other practitioners or other societies think—Should not mileage be considered? We must be prepared.—I am, Sir, yours faithfully,

T. L. ASHFORTH.
Woodlands, near Doncaster, Oct. 12th, 1911.

STRANGULATION WITHOUT VOMITING AND GENERAL PERITONITIS FOLLOWING PARESIS OF THE GUT.

To the Editor of THE LANCET.

SIR,—In your issue dated Sept. 23rd you commented on the absence of vomiting during strangulation. You mentioned that Sir James Paget regarded vomiting as one of the most constant symptoms, while another eminent authority, not so dogmatic, assigned it as being almost constant. In view of this conflicting testimony, the history of the following case, under the care of Mr. Jalland in the York County Hospital, may be of interest.

The patient was a male, aged 54. On admission his condition was good; temperature normal; pulse slow and full, having a frequency of 60; respirations numbered 20 to the minute. The patient complained of pain in the left inguinal region and showed tenderness over a swelling in that locality; in fact, a left femoral hernia presented. He maintained that the lump was always there; in any case it was absolutely irreducible, stony hard, with absence of impulse on coughing, and dulness on percussion. The bowels had acted during the morning, and with an enema a good result was obtained, together with flatus, the important item being that at no time had the patient vomited, though he stated he had a tendency to retch. The doctor who attended the patient prior to admission stated that the hernia was always reducible, and in view of this I cut into the swelling only to find a strangulated piece of gut with a fair amount of serous fluid in the sac. These facts show clearly that strangulation can exist without any history of vomiting; in fact, immediate operation was prompted by the reducible becoming irreducible.

Now this is only the initial stage of this unfortunate case. To continue. The strangulated bowel, having been washed in hot saline solution and marked with a small catgut stitch in the serous coat, was returned into the abdomen and a radical cure performed. After this, the patient's condition improved—e.g., he lost the tendency to retch, passed flatus, and felt fairly comfortable for at least 12 hours. This was followed by pain and tenderness in the left hypochondriac and lumbar regions. These increased both in severity and amplitude, and soon the whole abdomen became rigid; at the same time the patient acquired that pinched look so characteristic of peritonitis. It is worthy of note to state that the pulse had not altered, still maintaining its full character; and, indeed, it is notorious that in some cases of general peritonitis following a gangrenous appendix, you have the same class of pulse—one of almost normal frequency and good volume—probably due to a reflex inhibition of the heart or to direct stimulation of the vagi by the toxins circulating in the system. This stimulation is probably succeeded by paralysis, thus accounting for the running character that the pulse assumes before death.

To continue. Prompted by the foregoing considerations a laparotomy was performed 28 hours after the first operation and general peritonitis was discovered. However, the returned strangulated portion was absolutely indistinguishable from the rest of the gut. The whole gut was distended with gas, due no doubt to paresis following either the anæsthetic or an injured intestine; and in spite of all that was done, *mors* took place within two days.

The chain of events in this case is no doubt open to controversy, but this much is certain—that strangulation may exist without vomiting. The general peritonitis can only be explained by the transudate of pyogenic organisms through a paralysed gut.—I am, Sir, yours faithfully,

S. F. A. CHARLES, M.D.,
York, Oct. 9th, 1911. House Surgeon, County Hospital, York.

THE VIABILITY OF HUMAN CARCINOMA IN ANIMALS.

To the Editor of THE LANCET.

SIR,—In connexion with this question and in reference to the recent paper in your columns by Major C. L. Williams, I.M.S.,[1] may I mention that I was able, as shown in a similar series of experiments published in 1908,[2] to find mitoses after 16 days and well-preserved cells after seven weeks in pieces implanted into monkeys and mitoses after five days even in the frog. I think, as there stated, that there is much difference in the vitality of different tumours, or even parts of tumours, when transplanted into alien soil.

I am, Sir, yours faithfully,

A. S. GRÜNBAUM.
University of Leeds School of Medicine, Oct. 13th, 1911.

NOTE ON TWO CASES OF TUMOUR OF THE PREFRONTAL LOBE IN CRIMINALS.

To the Editor of THE LANCET.

SIR,—In regard to Dr. Tait's queries regarding the cases of prefrontal tumour published by me in THE LANCET of Oct. 7th, I find from my notes that the first patient was right-handed; I am not sure about the second. In the first case a small area of the cortex of the inferior frontal convolution about the anterior limb of the fissure of Sylvius appeared to the naked eye to be normal (it was not, however, examined histologically). The absence of aphasic symptoms would thus fit in very well with the apparent escape of the motor speech-centre.

I am, Sir, yours faithfully,

H.M. Prison, Holloway, Oct. 14th, 1911. W. C. SULLIVAN.

THE NOMENCLATURE OF SPINAL DEFORMITIES.

To the Editor of THE LANCET.

SIR,—Mr. Kellett Smith's letter unfortunately only adds to the confusion.

1. He states that a lateral curvature passes through three distinct stages, and then insists that the first of these three distinct stages must not be called scoliosis. One of the

[1] THE LANCET, vol. ii., 1911, p. 938.
[2] Journal of Pathology, vol. xii., p. 130.

objects of my letter was to emphasise the fact that the terms "lateral curvature" and "scoliosis" are synonymous.

2. He states that in the first stage the spine assumes a lateral curve without any rotation, and he applies to this variety of lateral curvature, which, he says, must not be called scoliosis, the term "lateral deviation"; yet as Lovett[1] has shown, lateral deviation never takes place without rotation, and W. Adams[2] even held that in lateral curvature the rotation takes place first and the lateral deviation afterwards.

3. He states that in the second stage, although the spine may be to some extent straightened out by posture, some of the deformity still remains owing to *bony displacement being maintained by muscular and ligamentous shortening*. But by the time there is any deformity that cannot be made to disappear by posture, the vertebræ and intervertebral discs have become wedge-shaped, and the plane of the superior and inferior articular processes altered in direction.

And finally, at the beginning of his letter Mr. Kellett Smith states that his three stages are distinct, and at the end of it, that they pass imperceptibly one into the other.

Now, Sir, what the practitioner wants to know, is whether there is bony deformity or not. If there is no bony deformity, then with plenty of fresh air and out-door exercise, with attention to posture and dress, the patient may completely recover; but if there is any bony deformity, then the practitioner may be certain that unless a proper course of treatment be adopted, the deformity will progress. How is he to tell if there is bony deformity? By making the patient, stripped to expose the iliac crests, bend down to the ground, thus completely flexing the spine. If the practitioner then observes the "horizon" of the back from different levels—I thank Mr. Kellett Smith for that valuable metaphor—he will at once notice any bony deformity; the ribs, or the erector spinæ in the lumbar region, will project more on one side than on the other.

If there is no projection on one side more than the other then the case is one of "postural scoliosis." If there is projection the case is one of "bony scoliosis." If the projection is only just enough to be noticed at all it is described as a "trace"; if it is easily seen it is described as "moderate"; if it is so noticeable as to be obvious to the untrained eye it is described as "severe"; and the very worst cases of all are described as "extreme." These four degrees are not distinct, but clinically they serve their purpose. The division into postural and bony scoliosis is, however, absolutely distinct, and I cannot too strongly emphasise its importance.

I am, Sir, yours faithfully,

Harley-street, W., Oct. 16th, 1911. PAUL B. ROTH.

IODISED PHENOL IN CHRONIC DISCHARGING SINUSES.

To the Editor of THE LANCET.

SIR,—Every surgeon knows the difficulty of curing a chronic discharging sinus. For some years I have treated, without a single failure or recurrence, long-standing as well as recent cases by the application of iodised phenol on a probe dressed with cotton-wool—Playfair's for large sinuses, an ordinary probe for small ones. These cases range from old tubercular hip sinuses down to small abscess sacs. In one case there were seven large and deep sinuses; in another the bare femur was struck by the probe. I once treated a Bartholinian abscess by dressing the sac in this way immediately after letting out the pus, and the wound healed without further discharge and without pain. Most cases require three or four dressings at intervals of a fortnight or three weeks. Contact is continued for about five minutes.

I am, Sir, yours faithfully,

DIGBY F. B. COTES, M.R.C.S. Eng.

Burton-on-Trent, Oct. 11th, 1911.

UNIVERSITY OF GLASGOW.—Mr. James Eric Paterson has gained the Brunton memorial prize of £10 awarded to the most distinguished graduate in medicine of the year.—The recently founded Struthers medal and prize in anatomy have been awarded to Dr. William B. M. Martin, Carnegie Fellow.

THE CORONATION DURBAR AT DELHI.

(FROM A SPECIAL CORRESPONDENT.)

Sanitation Arrangements.

IN view of the danger of epidemic disease, chiefly plague, cholera, or small-pox, occurring in and around the Delhi district during the Coronation Durbar, owing to the assembly of very large numbers of persons from different areas in India, in some of which the above diseases are constantly prevalent, and in view of the insufficiency of the ordinary civil law provisions for checking the outbreak and spread of these diseases, the following temporary regulations have been drawn up by the local government of the United Provinces under the Epidemic Diseases Act (III. of 1897). These regulations apply to the area in which the Delhi Durbar Act is in force, but do not apply within the limits of the Delhi municipality, except the civil station ward and that portion bounded by the Ridge, the Grand Trunk Road, and the Najafgarh Canal.

Administrative arrangements.—The general control of the epidemic disease operations will vest in the Coronation Durbar Committee. The district magistrate, or a magistrate of the first class deputed by him in writing, will be the Durbar executive epidemic diseases officer for the area contained within the civil ward of Delhi municipality, and the executive sanitary officer and the special magistrate for the Durbar will hold the same functions for the rest of the area to which the notification applies, subject to the control of the Durbar Committee. The Durbar Committee will appoint an executive epidemic diseases officer for every provincial camp or other suitable area, and a Durbar health officer and Durbar plague medical officer to supervise medical arrangements in connexion with epidemic diseases and plague within the whole Durbar area. The committee will also appoint a health officer for every provincial camp, under the general control of the administrative medical and sanitary officer for the Durbar. There will be one or more segregation hospitals for the Durbar area, and an observation hut or tent for the detention of suspicious cases in every central or provincial camp. No persons shall be removed to a segregation hospital without the sanction of a Durbar plague medical officer or health officer.

Sanitary precautions.—Power is given to a plague medical and health officer to order the compulsory cleansing of any house, hut, or tent which is in such an insanitary condition as to make the inmates specially liable to an attack of plague, cholera, or small-pox.

Notification of sickness and death.—Rules are laid down for the notification to the health officer of each camp of cases of sickness or death from contagious or infectious disease, or of excessive mortality among rats, and the health officer will report to the medical and sanitary administrative officer of the foreign and administrative camp.

Medical examination.—For the purpose of inquiring into suspected cases of plague, cholera, or small-pox a plague medical or health officer, or an officer not below the rank of assistant surgeon, deputed by him, is empowered to enter any place, with due precautions to safeguard as far as possible the social customs of the occupants. If possible the officer in question shall give an opportunity to the principal adult member of the family concerned to be present at the visit, and shall when possible be accompanied by the executive epidemic diseases officer of the camp. It is laid down that the inspection of women shall be conducted in accordance with the customs of the country, and no female shall be required to submit to examination by any other agency than that of a female medical officer or *dhai* (native female nurse). No compulsory corpse inspection for the purpose of discovering cases of plague, cholera, or small-pox is allowed, but the relatives of the deceased may submit a dead body to a plague medical or health officer for examination, if they wish to avoid the death being treated as due to one or other of the above diseases.

Removals to hospital and medical attendance.—In cases of plague, cholera, or small-pox, if the patient is unwilling to use a hospital, he may be removed to a suitable place where he and his attendants can be properly segregated; or if the place which the patient is occupying is suitable, segregation may be carried out there, subject to the sanction of the executive officer of the camp or area concerned. The opinion of a plague medical or health officer as to whether a place is or is

not suitable for isolation shall be final. No patient who has not a fair chance of recovery shall be removed except at the express wish of his friends. In all other cases patients may be removed compulsorily to a segregation hospital. Proper *purdah* arrangements will be maintained in removing *purdah nashin* persons to hospital and keeping them there. At least two friends may be permitted to attend on a patient. Patients will also be at liberty to employ *vaids* or *hakims* (native medical attendants) in preference to Government medical officers, and to receive visits from religious instructors, subject to the sanitary control of the plague medical or health officer.

Treatment of contacts.—Immediate attendants on a sick person are to be subject to the same isolation as a patient, and provision is made for the removal to a segregation hospital for 10 days, if a Durbar plague medical officer thinks it advisable, of all attendants on a sick person and other contacts. A daily inspection for 10 days may be substituted for segregation at the discretion of a Durbar plague medical or health officer.

Disinfection.—Powers are given to the plague medical and health officers for carrying out the disinfection of any place in which a case of plague, cholera, or small-pox has occurred or is suspected, and the disinfection and destruction of bedding, clothing, and articles of a similar nature, subject to due precaution for protecting the privacy of female members of the family concerned. Any place or any article adjacent to a place in which a case or suspected case of plague, cholera, or small-pox has occurred, and any other place or other articles in danger of infection may also be disinfected by a plague medical or health officer. If disinfection cannot be satisfactorily effected otherwise, the medical officer, with the sanction of the Durbar executive epidemic diseases officer concerned, may burn or otherwise demolish a hut or other temporary structure, and similarly he may destroy contaminated clothing or bedding.

Evacuation.—In addition to the evacuation of actually infected places, evacuation shall be compulsory also in the case of places suspected by a plague medical or health officer to be infected. Accommodation for persons so removed shall, if necessary, be supplied in suitable places. No places so evacuated shall be reoccupied without the sanction of a plague medical or health officer. All property may be removed from an evacuated place by the owner subject to disinfection. If the owner declines to remove it it will remain at his risk.

Disposal of corpses.—Rules are laid down for the burning of corpses, in cases where cremation is the custom, at the usual burning ghat or other isolated locality, and for the burial six feet deep of corpses in other cases.

Compensation.—The Durbar epidemic diseases executive officer concerned may pay compensation to any person who has sustained substantial loss or damage by reason of anything done under these regulations.

Duty of compliance.—Every person to whom an order is given by any officer empowered to act under these regulations, such order being in accordance with the regulations, is bound to obey that order.

LONDON SCHOOL OF TROPICAL MEDICINE.—The annual school dinner of the London School of Tropical Medicine was held on Oct. 17th, at Princes' Restaurant under the chairmanship of Dr. M. Cameron Blair, senior sanitary officer, Northern Nigeria. The toast of "The School" was proposed by Surgeon-General A. M. Branfoot, C.I.E., I.M.S., who paid a warm tribute to the part which was played by Mr. Chamberlain in the establishment of the institution. He referred to the progress which the school has made since its foundation 12 years ago. During this time 1238 students have passed through the school. The toast was acknowledged by the chairman and by Sir Patrick Manson, who in a humorous speech referred to the proposed extension of residential accommodation for students, and to the forthcoming issue of a Journal of the London School of Tropical Medicine. The toast of "The Guests" was proposed by Captain A. W. Clarke. Director-General Sir James Porter, in his reply, touched on the progress which has been made with the scheme for the new Naval Medical School at Greenwich, and indicated that the school would probably open in a small way early next year. "The Health of the Chairman" was proposed by Mr. James Cantlie, and was warmly received.

SOME REFLECTIONS ON THE INTERNATIONAL HYGIENE EXHIBITION AT DRESDEN.

(FROM OUR OWN CORRESPONDENT.)

THE British Government refused for many months to recognise the educational importance of the International Hygiene Exhibition. All attempts to impress on the various Ministers that a vast difference existed between this exhibition and every other exhibition yet organised fell upon deaf ears, and even the idea that a British participation might have a political significance was not entertained for one moment. In May the great organisation opened its doors in expectancy, but not even the sanguine administration had the pluck to anticipate such success as has since been achieved. Success in every direction has attended their endeavours, and we may congratulate ourselves that we share in this success.

There can be no doubt that a very strong feeling was rampant toward the end of August and during the early part of September on the subject of war. Every action of England was analysed with scrutiny, and a certain class of German citizens interpreted each sign as a further signal of hatred and unfriendly feeling of our country towards Germany. The very presence of a British pavilion at the Dresden Exhibition sufficed to counteract a fair amount of this bad feeling, not only in Saxony, but all over the empire, since Germans flocked in surprising numbers to the world's great educational effort. No more crushing denial to the rumour that England and Germany were antagonistic could be forthcoming than the fact that while France held a corner at the end of the beautiful Hercules Allee, for the first time taking part at a German exhibition since the Franco-Prussian War, Great Britain had its serious little hall guarding the entrance to the Fest Platz, and the men of science of England were constantly offering a welcome to the German people in the pavilion dedicated to the preservation of life. The administration of the exhibition recognised from the first what a gap would have been created if our country had been absent, and the warmth of the welcome on the part of the Germans to the British Committee and its representatives indicates that while political feeling may engender a bitter feeling against us as a nation, this feeling will never affect us as individuals as long as we do not give due cause.

Over five millions have paid their way through the turnstiles. These number came from near and from far, not with the idea of spending a good time in roundabouts, scenic railways, and the like, but with the intense purpose of learning something about health. The pavilions closed throughout the season at dusk, but not later than 7. During September, as the days drew in, the people were turned out of the halls, at first at 6.30, then at 6, and then at 5.30 P.M., and as the attendants cleared the pavilions the people inquired in almost despair where they could go save to the three or four pleasure halls. It was found advisable to light the popular pavilion with electricity and to keep it open until 10 in order to satisfy the public. On Sundays, when the crowds became denser than ever, the halls were so full that it was difficult to worm one's way into any of them. And yet they held firmly to their purpose and strained to see what was placed on show.

What the People Learned.

What did these masses learn? That their mission was not merely pretence or sight-seeing is proved by the fact that even when the crowd was at its height the Statistical Section was practically empty. The populace could not understand that. The Hall, "Der Mensch" (The Human Being), formed the chief attraction and the second was the Historical Section. In the former, for the first time in their lives, the uninitiated found themselves face to face with themselves. It would be too much to expect that they learned even elementary physiology, although the material exhibited was sufficient to give a clear insight into physiology of a somewhat advanced type. But the great mass saw and began to think. Simple lessons of the best way to carry out every-day problems, which are usually carried out wrongly, were driven completely home, but not all. Besides, the ordinary lesson on anatomy or physiology given to an unprepared individual

tends to leave the impression that life hangs on a thread, that the machine is so delicate, so complicated, and so much dependent on tiny arrangements, that the man dare scarcely move lest the whole machine refuses to act. Not so in "Der Mensch." The populace were able to measure the enormous power exercised by the heart 72 times in a minute, by the jaws when a nut has to be cracked, by the metabolism when a meal has been swallowed, and they learnt that all this goes on without the windows of the house breaking. They learned, too, that the body in health is far stronger than they had imagined, and they realised that each mechanism is so exact and so well planned that, granted a fairly reasonable treatment, things right themselves without much trouble. Not only were a number of the *noxæ* which might prove serious to the mechanism recognised, but above all the masses learned that the charlatan who talks mysteriously of the body and its functions knows nothing at all about it and must be dangerous. As a graphic demonstration of the dangers of quackery the Hygiene Exhibition was superb.

Next the masses learned that knowledge was possessed to a high degree in ancient times, and that this knowledge was lost in the middle ages. They saw how laborious was the work of building up again knowledge which had been scattered to the winds, and how much of the dangers and defects of our modern life are the results of our absurd habits and our ignorant ways. An open-mouthed gaze was seen repeatedly when the uneducated visitor was placed in front of the modern plant devised for the treatment of sewage, or the recent researches in illuminating, or even in the section dealing with infective diseases. Much was, no doubt, wrongly interpreted, but this is of little moment, as long as great principles were driven home.

The Exhibition and the Expert.

A different tale naturally applies to the expert, who found so much to study in his own line that days and even weeks were spent in one hall. Here was a record of all that modern investigations had revealed, while in the historical section the development of that branch of science in which he works found expression. Practical lessons were supplemented by theoretical ones, until, armed with a stack of catalogues and pamphlets, the expert left the exhibition a wiser, a wealthier, and perhaps a happier man. At times a municipality determined to employ a different method of dealing with house refuse or of disposing of the sewage. In these cases the experts were sent to study, not only what the Germans had exhibited in well-nigh perfect form, but also what each nation had to say of the various methods. A constant stream of expert visitors sought interviews with those in charge of the pavilions to inquire what the latter had to tell them, what publications were to be had on the special subject, and how further details could be acquired. School authorities compared notes, and the one set the other thinking. And so in every branch of hygiene. The seekers after truth and after human ingenuity came from every nation of the world, including England.

Our own pavilion met the same fate as the other halls in this respect. A considerable demand was made for a general account of the public health measures in our great cities. School children were among those who asked for pamphlets on general and special subjects, often without any distinct idea of what could be produced, but always with a veritable hunger for some form of knowledge. A striking observation could be made in each of the halls. While the mere man in the street wandered about, taking in what happened to present itself and what appealed to his mind as being interesting, the expert deliberately sought out exhibits bearing on his own subject, and armed with notebooks wrote pages on pages in order that nothing might be forgotten. The exhibits themselves frequently gave the impetus for further search, and then brochures, catalogues, and other publications were produced, until all the forthcoming details were found and duly catalogued in the notebook. To this he wished to add more, and so penetrating into the inner sanctum of the chief of the section, where such existed, he directed a bombardment of questions, all aimed at laying a foundation to a comprehensive knowledge of the matter in hand. Those who were unfortunate enough to be limited as far as time was concerned were compelled to satisfy themselves with headings, without details, and even in such cases the impressions would suffice to give a living colour to the subject.

Success of the Exhibition: Permanent Museum of Hygiene.

In general, the verdict of the expert, unanimously expressed, was that the food for study offered was well-nigh inexhaustible, and that the great pity of the thing was that such a collection should be distributed after the spell of a few months. This verdict, supported by the result of an excellent business management and favourable meteorological conditions, has led to a scheme being set up for the retention of at least a goodly part of this wonderful collection. The exhibition has been a brilliant financial success. Thanks to the foresight of the authorities heavy charges were made for space let to industrial firms. These charges appeared at first to be prohibitive, but time has proved that the sums spent were well invested in practically every case. It is indeed doubtful whether a flimsy firm exhibiting would have come out of the fire unscathed, but stable concerns rejoice that they had the courage of their opinions and participated at Dresden. Next, the great crowds brought grist to the mill, and the returns of this undertaking may be gathered from the fact that one week-day evening toward the middle of October when the Popular Hall opened at 6.30 with an extra entrance fee of 6*d*., over 3000 persons paid this fee within a single hour. The result was that long before the exhibition was closed there was a substantial profit. According to previous arrangements a material balance was to be utilised for the purpose of creating a permanent museum of hygiene. As time passed, it became clear that the authorities would be enabled to carry out the permanent museum scheme on a large scale. The site is still undetermined, and will depend on the amount which the organisers are prepared to spend on the building. However, Dresden is the most probable place. Next, the idea has been evolved that the whole will be more educative and more valuable, if set up as a historical representation of what is known of hygienic undertakings from the prehistoric times up to the year 1911. The basis will be those objects which have been specially made in the Historical Section. Of the 20,000 or so objects contained in this section, a good proportion have been created in the laboratories and workshops of the administration. Professor Sudhoff, Dr. Neustätter, and Mr. Kohl, assisted by a large army of experts, have evolved material which has only been guessed at before. Old manuscripts, pictures, broken odds and ends have been utilised for this purpose, and the marvellous models and schemes owe their existence to the great ingenuity of these able men. Next, the administration has wisely examined every object in all the halls, and has sought to acquire the things which would supplement the collection, more especially in regard to the modern development of hygiene. In many instances these objects have been dedicated. It is worthy of note that the British Committee, in recognition of the excellent objects of the scheme and in the wish to show its appreciation of the treatment meted out to it by the administration during the difficult period of its existence, has determined to give those exhibits which it has prepared specially for the British Section. In other cases the administration is purchasing the exhibits, and in still others, where the originals cannot be acquired, the administration, with the exhibitors' permission, is reproducing the exhibits either in model or in pictorial form. It is difficult to conceive at this stage the proportions of the permanent museum. Judging from the thousands of objects which are being set aside for the purpose, either in virtue of actual possession, or gift, or reproduction, or of purchase, the building will have to be the largest ever set aside for a museum.

Given that the educational value to student, expert, man in the street, and even yokel, of the International Hygiene Exhibition has been greater than can be measured in a few sentences, what will be the value of this future museum, which can easily be kept up to date year by year, for posterity? The place which the Popular Hall will take in the permanent museum does not appear to be quite clear. That it is to form a part, an important part, is certain, and tempting offers of purchase from the other side of the Atlantic have wisely been refused without hesitation, in view of the necessity of this collection for the greatest scientific nation in the world. The names of Dr. Luerssen, Dr. Ingelfinger, and of the members of their staff have become great through this colossal work. Splendid credit redounds to the names of the heads of the scientific departments—namely, Regierungsrat Dr. Weber of

the Kaiserliches Gesundheitsamt, Stabsarzt Dr. Xylander, Dr. Woithe, and Dr. Roessle. It is due to the excellent diplomatic and business capacities of Dr. Steinbach and Dr. Graupner that the running of the exhibition was so smooth and so successful. Many other names might well be added to the list of those who have contributed materially to the success of the most exceptional, the greatest, and the most scientific exhibition ever organised. Each has won his spurs. One other name, however, must be given—namely, that of Dr. Mallwitz, who has fought to popularise sport on hygienic lines and who has done wonders in a country in which sport is young. The Saxon Government has already recognised the value of the work done and has extended honours to the two Presidents. The one, Geheimer Kommerzienrat K. A. Lingner is now His Excellency, in recognition of his steadfast purpose in conceiving the plan and collecting the most skilled men of his country to carry it through. The other is a worthy scientist, a medical man of fame, Geheimer Medizinalrat Dr. Renk, who has been promoted to the title of Geheimer Rat. His general management of the scientific part of the undertaking was great. But with all the names of those who have deserved the thanks of the whole world, the chief thing about this undertaking is that the public has benefited by it to an extraordinary degree and those who did the work may reap their satisfaction by the appreciation of this fact.

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

Hospital Saturday Fund.

THE collections this year have reached the record of £21,463, being £1212 more than in 1910. This growth of the fund is encouraging to the committee, as they are embarking on a very considerable extension of their work in the maintenance of a new home for consumptives. £10,000 will be distributed as usual among the hospitals and nursing societies of the city, the chief items being: General Hospital, £3150; Queen's Hospital, £2100; General Dispensary, £1040; Children's Hospital, £800; Eye Hospital, £350; Women's Hospital, £500; and Orthopædic Hospital, £300. Altogether, 27 charities participate.

An important event occurred on Oct. 14th, when the Lord Mayor, Alderman Bowater, laid the foundation-stone of a new home for consumptives at Romsley Hill, near Rubery. The site, which is a gift from an anonymous donor, is 25 acres in extent, about one-third being woodland. It is on the southern slope of a hill between the Lickey and Clent Hills, and has an altitude of 800 ft. At the ceremony, which was presided over by Alderman Hallewell Rogers, the President, a large number of gentlemen connected with the public life of the city and of workers belonging to the movement were present. The home is intended as a memorial to the late Sir William Cook, who was for many years chairman of the Hospital Saturday movement and also of the Health Committee. An ambitious scheme was prepared, the original plans providing for a large building with central administrative quarters and accommodation for patients on each side. At present a start is being made with the central block and with one wing providing accommodation for 30 beds, 16 for men and 14 for women. The cost is £14,000, but another wing can be added later at a cost of £4250, when the accommodation will be increased to 60 beds.

A Change of Name.

At a special meeting of the supporters of the Midland Counties Asylum it has been decided to alter the title of the charity to "The Midland Counties Institution: A Training Home for the Feeble-minded." It was felt that the word "asylum" applied to an institution for the care and training of the feeble-minded was undesirable and misleading. Since 1868, when it was founded, several changes have been made in its description in order to keep abreast of popular sentiment, the most important being the omission of the word "idiot." Funds are asked for to increase the accommodation and render possible the separation of the sexes.

Post-Graduate Classes.

Post-graduate demonstrations, open to any medical practitioner, will be held at the General and Queen's Hospitals for six weeks commencing Oct. 31st, and on Jan. 23rd, 1912, also for six weeks. The demonstrations will take place on Tuesdays at the General Hospital and on Fridays at the Queen's Hospital. Practitioners wishing to join must apply, enclosing the registration fee of 5*s*., to the honorary secretary, the Queen's Hospital, who will send the names of lecturers and subjects. A series of demonstrations on the Modern Methods of Diagnosis and Treatment of Consumption will be held at the City Sanatorium, Yardley-road, by the visiting physician (Dr. W. H. Wynn) on Wednesdays from Nov. 8th to Dec. 13th at 3 30 P.M. Special attention will be paid to the use of tuberculin in diagnosis and treatment.

Birmingham and District Provident Dispensary.

This institution, which has been established nearly three years, for some reason does not seem to succeed so well as it deserves. The promoters early sought the advice and good will of the profession, and the medical representation on the central committee is ample and a pattern for similar institutions elsewhere. The members are very unequally distributed among the medical staff. In certain quarters there has been some hostility, the reason for which is not apparent.

Oct. 17th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

The Insurance Bill.

THE profession in and around Edinburgh seems to be maintaining a steadfast front with regard to this Bill. The Scottish branches of the British Medical Association have decided to hold a joint meeting in Edinburgh at the end of October, which, it is expected, will be addressed by Mr. J. Smith Whitaker and Dr. J. A. McDonald from the London headquarters of the Association.

Election of a Direct Representative for Scotland on the General Medical Council.

Dr. Norman Walker, whose five years' term of office as Direct Representative for Scotland upon the General Medical Council is now nearly completed, is offering himself for re-election, and his electioneering address will be found in the advertising columns of the present issue.

The Edinburgh Medical School.

With the beginning of this winter there are again changes in the medical curriculum at the Edinburgh Medical School. The student is now advised to begin his studies in summer instead of in winter. If he does so he is allowed to appear for the second professional examination—that is to say, for the subjects of anatomy and physiology—at the end of the second year of study. The third winter can thus be devoted to pathology, materia medica, and surgery. Fevers, diseases of children, mental diseases, diseases of the skin, ophthalmology, diseases of the throat, nose, and ear have all to be attended now during some time in the two last years, in addition to medicine, surgery, midwifery, public health, and medical jurisprudence. The student is no longer to be allowed to take the final examination in such sections as he chooses, but must take medicine, surgery, and midwifery together. It was found that the permission to take these subjects separately encouraged the undesirable system of cramming. A further regulation has been issued to the effect that every student must attend a course of tutorial instruction in physical examination, either before he clerks in the wards, or during his first term of attendance on clinical medicine.

Edinburgh School of Medicine for Women.

The number of students attending this school is maintained. The only changes in the teaching staff this winter are the appointment of Dr. Edwin Matthew as lecturer on systematic medicine in place of Dr. William Russell, resigned, and of Dr. G. L. Gulland as teacher in clinical medicine on his promotion to the full staff.

Changes in the Edinburgh Royal Infirmary.

Owing to the lamented death of Dr. Alexander Bruce there are changes this winter on the medical side of the Royal Infirmary which would not in ordinary course have taken place until next year. Dr. G. A. Gibson has moved into wards 30 and 33, Dr. W. Russell has moved into wards 29 and

30, Dr. Lovell Gulland has been promoted, from senior assistant physician, to wards 27 and 5, while Dr. J. J. Graham Brown has become senior assistant physician in charge of the incidental delirium ward No. 3. The new and recently appointed assistant physician is Dr. W. T. Ritchie.

Edinburgh Royal Medical Society.

This society is to have as its principal guest at the annual dinner this winter Professor Robert Saundby of Birmingham. Professor Saundby is an Edinburgh graduate and was a president of the society in the "seventies."

Inauguration Ceremony at Western Infirmary, Glasgow.

A new building in connexion with the Western Infirmary, consisting of a handsome pavilion with three wards, as well as a new clinical laboratory presented by an anonymous donor, was formally opened a few days ago by Sir James Barr, who took the opportunity to emphasise the need for research work with a view to the prevention of disease. At the same time he expressed the opinion that the new Insurance Bill, which he described as a great step in the downward path to Socialism and degeneracy, would encourage rather than prevent disease. The chairman of the infirmary, Sir Matthew Arthur, outlined the connexion of the Western Infirmary with the Glasgow Hospital for Skin Diseases from the year 1871, when an arrangement between the two institutions was arrived at whereby the outdoor cases were to be treated at the Skin Hospital, while two wards were to be set apart in the Western Infirmary for cases recommended from the Hospital for Skin Diseases for indoor treatment. After the death of Sir Thomas McCall Anderson in 1908 it was thought by the board of the Hospital for Skin Diseases that the two-fold object aimed at by the founders of the hospital—the gratuitous treatment of patients and the advancement of medical science—would be most effectively carried out by drawing closer the ties with the Western Infirmary and by the foundation of the McCall Anderson Memorial Lectureship in the University. The sum of £2500 was accordingly given by the Hospital for Skin Diseases to the University to endow the lectureship, and the remainder of the funds—£2300—was handed over to the infirmary for the endowment of beds. It was arranged that the dispensary work should be done in the Western Infirmary. The managers of the Western Infirmary welcomed the suggestion that one of the wards now in the new wing should be called the McCall Anderson's Memorial Ward, in grateful acknowledgement of Sir Thomas McCall Anderson's many services and in recognition of his distinguished career, and that the other should be called the A. B. Buchanan Memorial Ward, to associate it with the name of Sir Thomas McCall Anderson's colleague in the work of the Hospital for Skin Diseases during the early years of its existence. The third ward was due to the liberality of Mr. William Robertson, who gave £8500 to build and equip it, and a further sum of £3500 to provide an operating theatre.

Revised Regulation for the Carnegie Fees at Aberdeen University.

At a meeting of Aberdeen University Court, held on Oct. 10th, a communication from the Carnegie Trust was read stating that the demands for payments of class fees had considerably exceeded the available income, and it had become necessary to modify the scheme. In the case of present beneficiaries it was hoped to continue the payment of fees as formerly, but new beneficiaries would receive restricted benefits. The annual amount paid to the student of medicine would henceforward be £15, to be paid by means of coupons valued at £1 each, which, when signed by the beneficiary, would be accepted by the university authorities towards payment of ordinary class fees. There would be no value for fractions of a £; the beneficiary must himself pay the shillings in cash in case of guineas, and under no circumstances whatever was cash to be given in exchange for coupons or part thereof.

Aberdeen University Lecturer in Bio-Chemistry.

At a meeting of the Aberdeen University Court held on Oct. 10th, Mr. Edward S. Edie, M.A., B.Sc., was appointed lecturer in bio-chemistry in connexion with the physiological department of the University. Mr. Edie has been for some years director of chemical research in the Liverpool School of Tropical Medicine, and has done much valuable original work.

Opening of the University of St. Andrews.

The winter session of the University of St. Andrews was opened on Oct. 10th. In his opening address Principal Sir James Donaldson, in alluding to bursaries, said that money received in bursaries ought to be regarded as a sacred debt, and when the recipients attained to better circumstances they should apply the sum to the same noble purposes to which the original donors had dedicated the bursaries. In that way the students of a university should be, when they reached maturity, a great help to the university; they should show their interest in the working of it, and endeavour, when their means allowed, to establish facilities by which the able poor could obtain all the privileges of education.

Oct. 16th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Royal Academy of Medicine in Ireland.

THE annual general meeting of the Royal Academy of Medicine was held last week to hear the report of the council and to elect officers and sectional councils. The report stated that during the past session, 1910–11, the Fellows of the Academy numbered 181, the members 20, associates 2, and student associates 8. These figures show a reduction of three Fellows and two members, with one additional associate. The attendances at the meetings during the past session amount to 817. Last year, owing to special circumstances, the number was only 692; the two previous sessions were 731 and 753. This points to an increased interest in the meetings of the Academy. The accounts show a balance to the credit of the Academy in the National Bank of £262 6*s.* 5*d.*, as against a credit balance last year of £255 9*s.* 7*d.*, showing a small increase of £6 16*s.* 10*d.* The following officers and councils were elected: President, Sir Charles B. Ball, Bart.; general secretary, J. Alfred Scott; secretary for foreign correspondence, Sir John Moore. Medical Section: President, Sir John Moore; council, J. Craig, W. R. Dawson, H. C. Drury, J. A. Matson, T. G. Moorhead, J. F. O'Carroll, G. Peacocke, F. C. Purser, W. A. Winter. Surgical Section: President, R. H. Woods; council, C. A. Ball, A. J. M. Blayney, L. G. Gunn, W. S. Haughton, S. S. Pringle, H. Stokes, R. A. Stoney, E. H. Taylor, and W. I. de C. Wheeler. Obstetrical Section: President, A. J. Horne; council, J. S. Ashe, G. Fitzgibbon, A. N. Holmes, H. Jellett, T. Neill, R. D. Purefoy, J. S. Sheill, A. Smith, B. A. Solomons, and E. H. Tweedy. Pathological Section: President, A. H. White; council, A. H. Benson, W. Boxwell, J. B. Coleman, L. G. Gunn, W. G. Harvey, T. G. Moorhead, T. T. O'Farrell, W. D. O'Kelly, and R. J. Rowlette. Section of Anatomy and Physiology: President, E. P. McLoughlin; council, B. J. Collingwood, A. F. Dixon, A. C. Geddes, T. P. C. Kirkpatrick, A. A. McConnell, and N. C. Rutherford. Section of State Medicine: President, M. J. Nolan; council, A. E. Boyd, T. P. C. Kirkpatrick, J. A. Matson, G. E. Nesbitt, G. R. S. Stritch, and W. A. Winter.

Pensions in the Poor-law Service.

Some notable examples have occurred lately of the niggardliness with which boards of guardians treat medical officers who, through age or disability, are forced to retire from service. Poor-law medical officers have no claim to a retiring allowance, but it is open to guardians to grant such allowance according to a certain scale. The officer must first resign, however, before the question can be discussed. In one union recently the guardians granted an allowance of £40 a year after 21 years' service, although they could have granted £55.

Death of Mr. J. H. Chapman, F.R.C.P. Irel.

The death occurred on Oct. 15th of Mr. J. H. Chapman, a well-known Dublin physician. For some months he had been seriously ill, so that his death was not unexpected. In his younger days Mr. Chapman was a keen cricketer and the best underhand bowler in Ireland of his time. He was President of the Leinster Cricket Club, and rarely missed a good cricket match in Dublin. Mr. Chapman enjoyed a large practice and held several public appointments. He had been for many years honorary secretary, and subsequently President, of the Irish Medical Association. His death will be widely regretted.

Death of Dr. John S. Cargin.

Sincere regret was felt in Belfast on the announcement of the sad death of Dr. J. S. Cargin, of Holland House, Seabank-road, Liscard, Cheshire, which took place in Chester Infirmary on Oct. 6th as the result of a motor accident on Sept. 18th at Penymynedd, a little Flintshire village between Hawarden and Hope. Dr. Cargin and a friend in a small two-seated car came into collision at a right-angled crossing with a large car travelling along the high road. The friend was killed instantly, and Dr. Cargin sustained a fractured skull and internal lesions from which he has since died. The occupants of the other car fortunately escaped with comparatively slight injuries. Dr. Cargin, who was an Ulsterman, was educated at the Royal School, Dungannon, and at Queen's College, Belfast, and graduated as M.B. of the Royal University in 1900, and M.D. in 1905. During the Boxer rising in China he saw service in Peking with English, German, and Russian colleagues, and received honourable mention. He went to Liscard about six years ago in succession to Dr. Bristowe. He was a member of the Wallasey Medical Society, and medical referee to a number of assurance societies. He was most popular with his patients. Dr. Cargin was buried at Dromore, co. Down, on Oct. 10th.

Scarlet Fever Epidemic in Portadown.

A mild epidemic of scarlet fever is at present prevalent in Portadown. There are now 50 cases of fever in the Lurgan workhouse fever hospital, chiefly from Portadown.

Midwives or "Handy Women."

At a meeting of the Cookstown board of guardians held on Oct. 14th a motion to appoint a midwife for Coagh was defeated by 16 to 13 votes, and a similar motion for Pomeroy district by 15 to 14, notwithstanding that the Local Government Board had requested the guardians to meet especially to do so, and that its medical inspector, Dr. B. O'Brien, attended and spoke in support of such appointments.

The Water Famine.

The rain still keeps away in the North of Ireland and the water famine every day is becoming more acute. In Londonderry the supply will last but a few days longer, and water is being hawked round that city to be used only for drinking or for preparing food. A mass meeting of the citizens has urged the corporation to go in for a large scheme, by which that city would be permanently relieved from the dread of famine. The city council at a meeting on Oct. 16th decided to adopt the "Cabry" scheme, which various engineers have advocated. The reservoir which supplies the town of Monaghan is almost empty. Many of the larger merchants and bakers now cart water from lakes adjoining that town. Holywood is also in a deplorable condition. The reason why things are not so bad in Belfast is that a few hundred feet below the surface there seems to be an inexhaustible supply of "Cromac" water, largely used by all the manufacturers, who generally have an artesian well sunk on their premises, which makes them largely independent of the city supply.

Oct. 17th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Wireless Telegraphy and Anæmia.

ADMIRABLE as is the new invention of wireless telegraphy, and great as are the services it renders, already certain inconvenient results are making themselves evident among its operators. A French medical man, Dr. Auber of Peyrelongue, has paid particular attention to this question, and he finds that the wireless telegraphy operators on battleships are prone to be affected with a mild anæmia. This anæmia he finds to be the result of a combination of causes of unequal importance, but whose effects are synergic. The ozone must not be incriminated in all cases in the presence of circumstances of a strictly professional nature, though the same cannot be said of the nitrogenous products. The most probable factor is the confinement rather than the many other defective conditions to which the *personnel* is subject. As the most effectual prophylactic measure Dr. Auber recommends an open-air installation in peace time.

First Aid in Paris.

Public assistance is organised in Paris in the town halls, at temporary posts, and by movable ambulance stations on the occasion of public displays, also in first aid stations established on the banks of the Seine and of the canals, to render service in cases of submersion, violent death, death from natural causes, and confinement in public places, as well as in cases of accident and illness. The director, M. Thoinot, a member of the Academy of Medicine, has published his report on the aid thus rendered during 1910–11. Aid was rendered in 1670 cases, of which 321 were in cases of submersion, as against 1526 cases with 352 submersions in 1909. Out of this number in 232 cases the submersion was less than a minute, in 22 more than a minute, in 35 two minutes, and in 3 more than ten minutes. The last three persons could not be resuscitated. At the first-aid stations in 30 town halls 268 cases of injury, and 12 cases of illness received attention. The station of the fifteenth arrondissement alone received 114 wounded. The stretchers of the different posts were used 661 times for transport to the morgue, the hospitals, or to homes, in cases of accident in the public thoroughfares.

Medical Reforms.

On the resumption of work in regard to the Budget on Oct. 10th M. Thomson, speaking on the question of the universities and their supplies, called the attention of his colleagues to the urgent need of reform in the medical curriculum. He insisted on the unsatisfactory state of the equipment of the clinics and laboratories, and added that the decrees reforming the medical curriculum, which were passed as far back as 1909, had not yet been put in force. M. Viviani also insisted on the necessity for arriving at a speedy settlement.

The French Congress of Surgery.

The twenty-fourth Congress of the French Association of Surgery was held in Paris from Oct. 2nd to 7th under the presidency of Professor Segond, who delivered a splendid opening address. The diagnosis and treatment of chronic appendicitis formed the first subject, which was opened with communications by M. Silhol and M. Walther of Paris. Dr. Laplace of Philadelphia discussed the subject from the operation standpoint. M. Lanz of Amsterdam, M. Sonnenberg of Berlin, M. Richelot of Paris, M. Boeckel of Strasburg, M. Tédenat and M. Forgue of Montpellier, M. de Farkas of Budapest, M. Broca of Paris, M. Delagenière of Mans, M. Phocas of Athens, and MM. Lejars, Bégouin, Lambret, Auvray, Reynés, Mauny, Vanvers, Reymond, Paul Delbet, and Maurice Cazin in succession discussed the subject, giving their own personal experiences. Among other subjects dealt with must be mentioned the work of M. Duvergey on phlebitis in the evolution of uterine fibroma; that of Dr. Jayle on conservative surgery of inflammatory lesions of the uterus and annexa in one operation of MM. Cathelin, Boulanger, and Grandjean on the hospital statistics of 1000 reno-vesical cystoscopic explorations; and of M. Buscarlet on the treatment of vesical tuberculosis by insolation. The second subject in the orders of the day was the treatment of acute peritonitis. Professor Hortmann, and Dr. Témoin made the opening communications. The discussion gave occasion to interesting communications from MM. Kirmisson, Forgue, Sonnenberg, Depage, Montprofit, Delagenière, Thiéry, Auvray, Chibret, Savariaud, Vidal, Lecène, Lapeyre, Marquis, and Leriche. The third and last subject was the operative technique of the open treatment of simple fractures. The communications were made by MM. Alglave and Bernardet, and the discussion brought out the opinions of MM. Koch of Groningen, Lucas-Championnière, Depage, Lambotte, Willems, Ceci, Tuffier, Van Stokum, Thiéry, Herman, Princeteau, Dujarier, Gourdet, Paul Delbet, Lardennois, Dupuy, and Hocher. At the close of the Congress Professor Segond gave a delightful reception at the Palais d'Orsay.

Obituary Notes.

Dr. Pouillot, surgeon-major of the colonial troops, recently died a heroic death in Africa. He was in Commandant Hilaire's column at Beshéré and was returning with it, when he received a despatch ordering him to report at Abecher, where an epidemic of small-pox was threatening. Dr. Pouillot obeyed the order by a forced march. At a village through which he passed he was warned that the people being in revolt it would be imprudent for him to proceed, but,

listening only to the call of duty, he pushed on. The next day he was surrounded while passing through a village by 600 armed men, and he and his small escort were massacred. —Dr. Griffon, while performing an operation for empyema, infected an abrasion on his neck with the pus that spirted from the pleural incision. A fatal phlegmon ensued.

Cholera Infantum and Housing Accommodation.

AT a recent meeting of the Verein für Innere Medicin Dr. Rietschel of Dresden read a paper on cholera infantum in connexion with the problem of housing. He drew his hearers' attention to the fact that this disease only became known at a time when questions of house accommodation presented difficulties because of the great increase of large cities. The first description of the disease came from America as early as the year 1789, and on this occasion it was expressly said to have been observed only in towns and not in country places; but in 1835 the editor of a German journal when reviewing the American statistics of infant mortality mentioned that he had some doubts as to whether cholera infantum was in reality an entirely American disease. During the "sixties" and "seventies" of the nineteenth century, when the cities of Germany began their marvellous development, cholera infantum spread in a remarkable way and continued to increase until about the year 1900. It was generally admitted that the disease had a relation to the summer temperature, and that it was more frequent in certain districts and streets, and even in certain houses, than in others. Dr. Rietschel maintained that there was a connexion between infantile mortality and certain classes of dwellings the temperature of which was habitually above the average. He said that the temperature of a room depended not only on the temperature of the external air, but also on the size of the room and the number of people living in it; cooking was another cause of the overheating of rooms. These were the reasons which in Dr. Rietschel's opinion made cholera infantum so extremely frequent among the poor. On taking the temperature of the dwellings of poor people during a week he found that it did not fall below 24° C., and that it sometimes rose to 36°. He did not consider that the increased mortality was due either to the heat acting on the milk consumed by the children or to the decomposition of the milk by bacteria. He was of opinion that the heat acted directly on the infant. This was made obvious by the fact that infants in the best of health showed a slight rise of body temperature in a very hot room, and when this was continued for a period of weeks the vitality of the infants and their power of resistance to illness became very much impaired, so that an indisposition originating with slight dyspepsia might prove fatal. With a view to lessening the mortality of infants in summer time it was therefore desirable to avoid a high temperature in the living-rooms, to prescribe cold baths, and to bring the infant as much as possible into shaded places in the open air. Breast-feeding was, of course, essential for the prevention of disorders of digestion.

Assistance for Discharged Asylum Patients and Feeble-minded Persons.

Alienists have for a long time been recommending that something ought to be done by way of after-care for patients who have been discharged from lunatic asylums as recovered, and also for the assistance of feeble-minded persons who, though not actually requiring asylum treatment, are nevertheless unfit for the struggle of life. This course has been especially advocated by Dr. Möli, chief medical officer to the Herzberge asylum of the city of Berlin, and the municipality of this city will now establish an office of which an alienist will be the head, the idea being that these persons require the care of a specialist. When a patient is fit for discharge from one of the municipal lunatic asylums notice will be given to this office, the authorities of which will see that the patient finds proper lodging in a family willing to receive such persons and to allow supervision of them by visitors acting on behalf of the office. The office will also undertake to find employment for patients according to their capacity for work. When the mental disorder has apparently been due to over-indulgence in alcoholic liquors the office will work in connexion with temperance societies and will recommend the patient to become a member of such a society. Patients will not only be assisted in obtaining the necessities of life but in other ways as well; legal advice, for instance, will be given if required. In addition to the medical officer, nurses who have had experience of mental cases will be engaged by the new institution, and there will be voluntary members who will assist the salaried staff.

Simulation of Albuminuria.

Dr Hadda, physician to the Jewish Hospital in Breslau, has published in the *Berliner Klinische Wochenschrift* an interesting case of simulated albuminuria. The patient was a girl 12 years of age, who had suffered from severe sore-throat and subsequently from albuminuria, œdema, and slight symptoms of uræmia. These symptoms disappeared completely in February, 1910, and she was considered to have recovered. Albuminuria, however, again appeared in November, and the mother of the patient declared that she had observed great masses of mucus in the urine. The medical practitioner in attendance accordingly sent the patient to the hospital for catheterisation of the ureter; but when it was found that the first discharged urine contained 0·125 per cent. of albumin and only very few leucocytes catheterisation was not performed, and the patient's mother was advised to give notice when something abnormal appeared in the urine. Six weeks later the mother again brought her to the hospital declaring that the former symptoms had returned. The first urine obtained by catheterisation of the bladder did not contain albumin, neither did the second portion passed in the afternoon, but on the following morning an enormous quantity of albumin was present. There was no indication of either œdema or headache or alteration of the pulse, and the specific gravity of the urine was only 1026. The quantity of albumin was so great that it could not be measured by the usual Esbach albuminometer. The same thing happened again during the next few days, and the case appeared very obscure until the suspicion was expressed that the mother, who used to be in the patient's room from the early morning, had added white of egg to the normal urine. A quantity of the first morning urine was therefore secretly removed previously to the arrival of the mother, and on examination was found to be absolutely normal. The remainder of the same urine was examined after the mother's arrival and then contained a large quantity of albumin. It was therefore obvious that albumin had been added artificially, and a chemist, who also examined the urine, stated that the albumin was egg-albumin. The reason why the mother had tried to deceive the physicians was because she hoped to receive more money from the guardian of the child when the latter was ill. The family medical man afterwards informed the hospital authorities that the child after her discharge remained in perfect health.

Oct. 16th.

CANADA.

(FROM OUR OWN CORRESPONDENT.)

Toronto's Water-supply.

AT a meeting of the Board of Health of the city of Toronto on Oct. 5th Dr. G. G. Nasmith, director of the board's laboratories, gave expression to some statements and opinions which apparently startled and disconcerted that body. For two years there has been under construction on Toronto Island a sand filtration plant at a cost of £150,000. The citizens have been boiling practically all their drinking water for the past three years and waiting patiently for the completion of this plant, in order to ensure pure water for domestic purpose; and now Dr. Nasmith states that, "while the city has been occupying two years in building a filtration plant, the advance of science has declared the plant an antiquated piece of machinery." Moreover, the city has spent upwards of £400,000 in overhauling its sewerage system and constructing a trunk sewer to empty the sewage some four or five miles east of the city into Lake Ontario at a point known as the Woodbine. During the past months another problem has had to be dealt with—namely, that of laying a new intake pipe beyond the island, extending it further into Lake Ontario, and from a point known as Fisherman's Island. Dr. Nasmith states that the water off

this island will be polluted with at least 28,000,000 gallons of fresh sewage every day. He goes on to say: "From what I have seen this summer I have little doubt but that at times this polluted water will be carried to and beyond our present intake, or any other intake that may be subsequently laid." Dr. Nasmith further says that with all care it is impossible, with the sewerage system as it is now being constructed, to hope to keep all untreated sewage out of Lake Ontario all the time, and, therefore, even should the main effluent from the sedimentation tubes be chlorinated, both filtration and sterilisation must be used to obtain pure water. Toronto's water, drawn from Lake Ontario, passing under Toronto Bay through a concrete tunnel constructed a few years ago and reaching the mainland in the city at the foot of John-street, where the main pumping-station is situated, is pumped for the northern section to the reservoir on the hill north of the city, in Deer Park, and for the southern portion directly into the mains. At the pumping-station chlorination has proceeded for some months with distinct advantage from a sanitary standpoint and also with considerable complaint, particularly as to palatability, on the part of citizens. Into Toronto Bay, lying between the mainland and Toronto Island, the sewage of Toronto has been poured for years. At either end of this bay are gaps or water passages, known as the Eastern and Western Gaps. It will thus be apparent, he says, how easily currents of sewage-polluted water may at times flow almost directly from the Eastern or Western Gap to any intake pipe that may be placed within a radius of several miles from the city, though it is also apparent that in general terms the farther away from the source of pollution and the deeper the water, the greater will be the dilution of sewage, and therefore the greater the safety. The conditions which are causing pollution of Lake Ontario in the vicinity of Toronto at present will, however, change in a short time. When the sewage of the entire city is collected by the new trunk sewers and carried to the Woodbine, and after passing through the Watson sedimentation tanks is deposited in the lake opposite Fisherman's Island, an entirely new set of conditions will be inaugurated. The best, however, that these tanks will do will be to remove 50 per cent. of the suspended matter in well-screened sewage. Dr. Nasmith goes on to suggest three methods of lessening the danger to the citizens of Toronto arising from pollution of its water-supply: (1) By chlorinating the sewage effluent, which, according to one authority, will destroy over 90 per cent. of the pathogenic organisms; (2) by adding biological oxidising beds to the sedimentation tanks; and (3) by sterilising the filtered water. Following these suggestions the local board of health has decided to establish a chlorination outfit in connexion with the filtration plant on Toronto Island, to be used if occasion requires, and also to chlorinate the effluent from the sewage disposal plant. In order, no doubt, to dispose of those persons who, prior to the undertaking of the construction of the filtration plant and the tunnel under the bay, advocated that the Toronto water-supply should be drawn from Lake Simcoe, 50 miles north of the city, Dr. Nasmith reported from samples taken from that lake, that the "bacillus coli was proved out on two occasions," and that a gas-producing organism, which did not prove to be bacillus coli, was found in 15 samples. Accordingly the analyst pronounced against securing Toronto's water-supply from Lake Simcoe.

Diseased Meat Sold in Toronto.

In the monthly bulletin of the Toronto Board of Health Dr. Charles J. Hastings, medical officer of health, states that approximately 500 head of cattle are killed weekly in the 20 abattoirs of the city. Attached to the medical officer of health there are now three veterinary officers in place of one. These three officers are able to make only 116 post-mortem examinations a week. Of these 116 carcasses, 13 on the average are found to be diseased, and 13 carcasses or portions of carcasses are condemned weekly. Among the diseases found are actinomycosis, tuberculosis, sapræmia, abscess, parasites, and new growths. When these figures—which are the averages for the past nine weeks, the lightest killing weeks of the whole year—are taken into consideration, and it is remembered that the percentage inspected of those killed was 23·2, the percentage of diseased was 11·2, and that out of the 500 killed weekly some 55 are probably diseased, this diseased meat being placed on the market without inspection, it is little wonder that some are inquiring if there is any "jungle" business in Toronto. If the 20 abattoirs all kill at the same time, the three veterinary officers can inspect only three of them. Dr. Hastings advocates the construction of one large municipal abattoir where an efficient inspection of every animal killed could be made. The objection to this, however, is that it would strengthen the system, which is now accused of keeping up and increasing the cost of living. Apparently the question of efficient inspection is one merely of expense; and now that the citizens are enlightened as to the conditions, the civic authorities will have to take immediate steps to eliminate any appearance of this evil.

Consumption in Toronto.

There are at the present time 418 cases of tuberculosis under the supervision of the Toronto municipal nurses, 113 of these cases being registered by physicians and 117 of them being in sanatoriums. The health officer fears, however, that there are a thousand or more cases unknown to the city health authorities, even though compulsory notification is now in vogue, and that these may infect their families, friends, and fellow-workers.

Infant Mortality in Ontario.

Ontario has issued its second special report on infant mortality, the first being, so far as can be ascertained, the first instance in which any similar report has been issued by any Government. Both these reports have been specially prepared by Dr. Helen MacMurchy of Toronto. The author has gone far afield to gather material for this report, which is a comprehensive exposition of conditions prevailing and work being done in different parts of the world. It points out that in Toronto 7618 children were born in 1908, and that 1215 of them, or 159 in 1000, died before they were a year old. Stillbirths are not included in the above figures. Illustrations show a row of ten houses in Toronto with one water-tap at the end for their sole water-supply; four houses with only one sanitary convenience; and six houses, containing 50 persons, with only two sanitary conveniences. To attend to the slums and housing problem in Toronto, therefore, the medical health officer has his work cut out. In Ontario the number of illegitimate births in 1908 was 819. There is no separate record of deaths in those under one year. The baby farmer is not unknown in Ontario; £10 is the fee for adoption. There is no system of licensing and registering midwives in Ontario. This is a necessary thing, the report says, and should no longer be delayed. It is doubtful if in Ontario 90 per cent. of the births are registered. The report of the Registrar-General for Ontario for 1908 gives 55,388 births; deaths under one year, 6895; infant mortality rate, 125 per 1000. The highest rate was in the capital, Ottawa, with 521 deaths out of 2035 births, or 256·0 per 1000. The lowest rate was in Woodstock—viz., 98·0.

Registration at McGill University, Montreal.

On Oct. 5th the registration at McGill University for the season 1911–12 shows that the number of first year students in arts and science surpasses all previous records. The first year medical students amount to 71 to date, which is about one-fourth of the entire medical student-body, and is a gratifying increase over any freshmen medical class for the past six years. In science, a department famous the world over, there are 509 students, the freshman class comprising 156.

Oct. 6th.

UNITED STATES OF AMERICA.

(FROM OUR OWN CORRESPONDENTS.)

An Exhibition of Pure Foods.

THE second annual Exhibition of Pure Foods was held at Madison-square Garden, New York, from Sept. 23rd to Oct. 4th. Only manufacturers of preserved goods who eschew the use of artificial preservatives, such as benzoate of soda, were represented, and the exhibition comprised hundreds of varieties of preserved foods, from soup to nuts and raisins and cheese. In an exhibit of adulterated tinned foods a demonstrator showed a doll the clothing of which was dyed solely with the colouring matter taken from ketchup, tomato, and vegetable soup; a steel hatpin was dipped into

a tin of *petits pois* and when withdrawn showed a brilliant plating of pure copper. Strawberry jam was proved to contain only the cores of apples, grass seed, and eosin, with sometimes a little gelatin. Boric acid was shown to exist in many varieties of potted cheese, and the salicylates in many tins of the cheaper condensed soups. An especially interesting feature was 12 babies reared solely on tested milk from the stations established by the New York Milk Committee. A nurse in charge lectured to mothers on the dangers of trying to raise a baby on beefsteak, water-melon, and candy, and, in the case of German and Hungarian mothers, on beer. A different group of babies was shown daily and each was weighed in public. Lectures were given on the various problems presented by foods and other domestic matters. Two large ranges were in constant use, one in the charge of an army cook, the other under the supervision of a "doctor" from the galley of one of the new Dreadnoughts, demonstrating the economical catering in the Federal public services. The new paper-bag cooking received earnest attention in view of the servant problem. Food placed in the specially made paper bags was cooked in the oven and stewed in its own juice with remarkable results as to flavour and economy. The bags were then thrown away, the labour of cleaning and scraping pots and pans being thus abolished. The idea is a modification of the older self-basting baking pan.

Meeting of the American Hospital Association.

At the American Hospital Association, whose recent meeting was referred to in THE LANCET of Oct. 7th, p. 1047, the secretary of the State Board of Charities of New York said that New York was a generation behind the age in ambulance and other public hospital facilities. £600,000 have recently been appropriated by the city for modernising the hospitals, and it is hoped soon to consolidate under one head the Department of Public Charities, the Department of Health, and the Trustees of Bellevue and Allied Hospitals. Despite four training schools, much of the work of caring for patients is carried on by hospital helpers, nearly 1000 of whom receive wages of barely 2*s*. a day. More than 8000 changes have been made in a single year on account of the general inefficiency. In one of the Health Department's hospitals there are as many as six children in one bed. In the lower part of the city there is no organised ambulance service at all, and the city depends upon a charitable organisation for its altogether inadequate help. A new motor ambulance was exhibited which in time will probably replace horse-drawn vehicles. Dr. Walter S. Goodale, superintendent of a Buffalo hospital, exhibited his new ambulance for infectious cases. Its unique feature is the lining, consisting of an aluminium box strengthened with channel steel, which can be slid in and out of the body of the vehicle. After use the lining is removed and sterilised either by live steam or by burning formaldehyde candles inside. There are five such linings, so that a sterile one is always at hand. Each is mounted on wheels in the garage, so that two attendants can change linings in a few moments. Each lining weighs about 300 pounds. It can readily be adapted to an ordinary ambulance of sufficient size.

A Ferryboat as a School.

The New York Committee for the Prevention of Tuberculosis has fitted up an old ferryboat as a school for tuberculous children. The children do all their school work on board, have their meals in the open air, and are under constant supervision by a physician and a nurse.

Public Drinking Cups Abolished in New York City.

By the new Sanitary Code ordinance which came into force in New York City on Oct. 1st, public drinking cups have been legally abolished in hotels, public schools, railroad stations, factories, theatres, and all public places. In schools and factories drinking cups must be provided by children and workers, and it will be a violation of the law to use another person's cup.

The American Electro-Therapeutic Association.

This association held its twenty-first annual meeting at Philadelphia from Sept. 5th to 7th, under the presidency of Dr. Frederic de Kraft, who delivered his presidential address on the Development of High Potential Currents as Applied to Medical Uses. Dr. G. B. Massey, of Philadelphia, in a report on the Direct Continuous Current, urged the paying of greater attention to medicamental ionisation with low voltage currents. Dr. Frederick M. Law, of New York, in a report on Induced Currents, including the alternating and high-frequency current and apparatus, said that in using the d'Arsonval current the amount of dielectric rendered the therapeutic effect more superficial so that the influence was felt more on the sensory nerve endings. The current was of value in intestinal auto-intoxications. The bipolar current might be dangercus unless carefully used. Dr. F. Howard Humphris of London described Professor Bergonié's method of electrically stimulating the muscles for the treatment of obesity. He also read a paper on the use of compressed gases for increasing the efficiency of the static machine. Dr. Edward C. Titus of New York, in a report on phototherapy, considered that its effects were attributable not to heat but to certain invisible, non-caloric, luminous radiations. Dr. W. Benham Snow of New York recommended the establishment of standards for the employment of electro-therapeutic and other physical measures. In a report on the rational treatment of cardio-vascular disease, Dr. Snow said that in tachycardia, due to thyroid hypersecretion, X rays promptly relieved the tachycardia and dyspnœa. He considered the auto-condensation method of treatment of hypertension most valuable, except in cases where parenchymatous nephritis was present. Dr. G. E. Pfahler showed a muffle for the static or high-frequency spark. Dr. D. H. Yates, of Madison, Fla., reported three cases of pellagra treated by high potential currents. Dr. G. Betton Massey, of Philadelphia, read a preliminary note on arsenionisation in inoperable cancer followed by improvement in the general health. Many other papers were read. Richmond, Va., was chosen for the place of meeting next year.

Dr. Wiley at the Conservation Congress.

The attempts to oust Dr. Wiley from the position as head of the Bureau of Chemistry of the United States Department of Agriculture have resulted in a remarkable public expression of opinion. The enemies of the leader of the campaign for pure food and drugs in the United States are strong in influence and money, and they have omitted nothing to accomplish his political ruin. Although certain recent judicial decisions have nullified much of the Bureau of Chemistry's good work the outcome of the effort to expel Dr. Wiley has shown clearly that the community at large is with him. Speaking recently at the Conservation Congress at Kansas City Dr. Wiley stigmatised as "a thief and a corrupter of public morals" the man who substitutes ground peanut shells for pepper, who puts poisonous dyes into children's candies, or keeps wholesome food in storage until the taste has vanished and poisonous products have developed. He made a strong plea for a National Department of Health, and urged the public not to be deterred by the cry of a "doctors' trust."

Oct. 3rd.

NOTES FROM CHINA.

(FROM OUR OWN CORRESPONDENT.)

Flood and Famine in China.

EVERY present symptom points to the fact that the distress in China during the coming autumn and winter will be almost without parallel in the Empire's history. There are sad tidings of inundations from various provinces, but mainly from the valley of the Yangtze River, where over 100,000 people have been drowned or starved to death. Relapsing or famine fever has broken out among groups of refugees huddled together on hills or in towns to which they have fled. Owing, it is said, to a combination of heavy rainfalls and late melting of snow in the mountain ranges of Thibet, the Yangtze has risen to such an extent that in some places it is now only bounded by the ranges of hills which rise many miles from the banks. It is not possible to quote actual figures, but the appalling nature of the disaster may be appreciated when, to quote from the *North China Daily News*, the best informed paper in China, "it would probably be no exaggeration to suppose that half the population of the Yangtze Valley will have to depend upon charity throughout the winter or starve." As this population numbers over 100,000,000, it will be seen that the ruin has been widespread. At the city of Nanking 70,000 refugees have

gathered. Cholera is rife among them, and typhus fever is said to be equally bad, so that the death-rate is reported to be between 200 and 300 a day. Food has been sent to them, but under the awful conditions now prevailing there it is next to impossible for medical science to do anything. Corpses are seen floating about in large numbers. The whole matter has now got beyond the scope of charitable efforts, and the Central Government is being impressed with the need of undertaking some comprehensive scheme of relief. The condition of the Yangtze Valley has been described as a burning disgrace to the history of any nation. Rivers and canals have been embanked instead of dredged until their very beds are many feet above the level of the surrounding country. Hillsides have been recklessly denuded of trees, so that their alluvial soil is washed down in ever-increasing quantity, silting up the river beds. In some hands these disasters are callously regarded as a part of Nature's provision, terrible but necessary, to keep down the surplus population of this prolific race, but such a tame acceptance of such drastic laws of Nature is against the spirit of the age. What is wanted is a central irrigation board maintained by special funds, as in the case of the public works department in India. Meanwhile there is noticeable among Europeans and others in China a certain abatement of charitable enthusiasm due to the malversation of famine funds by various local officials and the heartless "cornering" of foodstuffs (especially rice) by native dealers.

Case of Abdominal Streptotrichosis.

It may be of interest to add to the literature of streptotrichosis a case recorded in the *China Medical Journal* by Mr. A. F. Cole and Mr. G. J. Evans of Ningpo. A Chinese farmer, aged 54, came under their notice suffering from a large fluctuating immoveable mass in the left iliac fossa. It was continuous with an indurated mass extending into the right iliac region, and the upper margin of this was very sharply marked on palpation. The growth had first appeared four months previously, and there were no other symptoms of importance. The patient was not particularly ill nor was he wasted. On operation three ounces of yellowish pus were removed in which were very numerous yellow granules of various sizes, chiefly about 1/16 inch in diameter. The wound healed up completely in the three weeks he was under observation, during which time he was given iodide of potassium in doses gradually increasing up to a drachm per diem. Microscopical examination of the pus at the time of operation showed dense masses of felted mycelium, but no clubs were visible in potash solution. Simple staining and the Gram-eosin method demonstrated branching mycelium and in a few cases thickenings resembling clubs. No other organisms were noticed, nor did they grow on agar or glycerine agar, which produced a very limited growth of the streptothrix only. The case was regarded as one of infection by a very fine sporothrix. The patient died about six months after leaving hospital. It is well that the case has been reported in the *China Medical Journal*, as in this land of abundant tuberculosis in all its forms it may be found by other medical men whose attention is drawn to the matter that some or many of their cases ascribed to the bacillus of tuberculosis would be more accurately included among the streptothricæ, and possibly future reports may show that there are streptotrichoses peculiar to China.

Death of Dr. Lillie E. V. Saville.

Dr. Lillie Saville was well known in North China, and her death, which occurred at the beginning of this month, is deeply deplored. She succumbed to an attack of cerebro-spinal meningitis. During the past few years there have been a number of sporadic cases of this disease among Europeans at Tientsin, and its etiology has puzzled the local medical men since it occurs at indefinite intervals without any epidemic incidence. Dr. Saville studied medicine in Edinburgh where she qualified, and later she received the degree of M.D. at Brussels. In 1895 she was sent out by the London Missionary Society to Peking to take charge of the society's medical work for women. She went through the siege of Peking in 1900 and did heroic work, for which she was decorated with the Royal Red Cross. Some years later she broke down in health from overwork and returned to England. In 1909 she came back to China, having been appointed to the Imperial Government Hospital for Women at Tientsin, where she died. Dr. Saville was a woman of more than ordinary ability and an exceedingly able surgeon. Her tireless energy and ambition to make her hospital a success, as also her efforts to bring the benefits of Western medicine to Chinese women, were evidently too much of a drain on her physical resources.

Peking, Sept. 23rd.

Obituary.

SIR H. J. BLANC, K.C.V.O., M.D. MONTPELLIER,

DEPUTY SURGEON-GENERAL, INDIAN MEDICAL SERVICE.

BY the death of Sir Henri Jules Blanc in Paris on Sept. 30th (recorded in THE LANCET of Oct. 7th) a man of mark, of influence, and of historic interest, has passed from our profession. Born in 1831, he had just completed his eighty years, and in their course had passed a varied and adventurous life. Shortly after his graduation at the University of Montpellier he joined the allied forces in the Crimea, and there saw something of the privations and trials of war. After his return he entered as an assistant surgeon in the Bombay Medical Service, and in that rank served during the China war of 1857–60, where again he had the experience for which his courage and his capacity well fitted him. Selected in 1867 to accompany as its surgeon the mission sent to Abyssinia, he, with its other members, was seized by King Theodore and treated with great cruelty as his prisoner. Upon more than one occasion they were led out for execution, when, being placed at the end of a long line of fellow-captives, they saw them hurled one by one over a precipice, and only when their own turn seemed certain was the performance arrested. This experience, however, did not daunt Sir Henri Blanc, for it has been told of him that upon one occasion, the cruelty of the treatment having been greater than usual, he personally remonstrated, and this in strong terms, with the king, and by thus acting rather gained than lost in his favour. King Theodore was a tyrant, but an unquestionably brave man, and he admired and gave credit to the courage of another. With his release and the storming of Magdala, in which he bore a part, this trying period came to an end, and after receiving a considerable sum of money in compensation for his sufferings, Sir Henri Blanc, on his return to India, was appointed a physician and afterwards a surgeon to the Grant Medical College at Bombay. The latter position he occupied for a good many years, lecturing upon surgery and doing a large amount of operative work. Through the excellence of this work he gained a wide and notable reputation, and his skill principally in operations for vesical calculus brought him from native rulers some princely rewards. In 1887, his health having given way, he retired from the service with the honorary rank of Deputy Surgeon-General, and settled in Cannes. There, with vigour happily restored, he soon formed a large and select practice, and had in his *clientèle* many whose names are to-day well known in the Courts of Europe. To the late King Edward, when Prince of Wales, he proved of signal service, the reward for which came to him in the K.C.V.O., given immediately after the King's accession.

A man of strong and striking personality, of iron will, of the highest courage and resolution, with great natural capacity and wide and well-garnered clinical knowledge, he was peculiarly well fitted for the various positions he was called upon to occupy. How great was the impression made upon him by the stern days of the Abyssinian captivity was evidenced by the fact that in his room, and close by his side, hung the heavy fetters that had then bound him; and it was a sad thought to those who, in the later days of his life, had the privilege of attending him professionally to feel that he was then bound by stronger fetters than those of King Theodore—fetters from which there was no escape and no release on this side of Time, and yet he bore these with as true and great a courage as he had done those of iron.

WILLIAM RICHARD HUGGARD, M.D., M.CH. R.U.I., F.R.C.P. LOND., LL.D.

WE regret to announce the death of Dr. William Richard Huggard, British Consul at Davos, Switzerland, which took place on Tuesday, Oct. 10th. He received his medical education at Queen's College, Galway, at Queen's

College, Belfast, at University College, London, and in Geneva and Vienna. In 1875 he took the M.D. and M.Ch. degrees of the Royal University of Ireland, and in 1880 became a Member of the Royal College of Physicians of London, obtaining the Fellowship of that College in 1898. Eleven years later the Royal University of Ireland conferred upon him the honorary degree of LL.D. "as one of its most distinguished graduates." Formerly he was physician to St. Pancras and Northern Dispensary, Euston-road, London. His contributions to medical literature comprise a Handbook of Climatic Treatment, including Balneology, which was published in 1906, and several articles in the medical press on the subjects of lunacy and phthisis. In 1885 we printed in THE LANCET a report by Dr Huggard on some experiments on the excitable area of the cerebral cortex which he had witnessed in the clinic of Professor Schiff.

CHARLES VERNON HITCHINS, M.R.C.S. ENG., L.S.A.

Mr. Charles Vernon Hitchins died at his residence in Weston-super-Mare, Somerset, on Oct. 11th, in his eighty-fifth year. He was born at Bath, received his medical education at St. Bartholomew's Hospital, and qualified M.R.C.S. Eng. and L.S.A. in 1854. Mr. Hitchins went to Weston-super-Mare in 1857. Two years later he was appointed medical officer of health for the town. He was at one time district medical officer for the urban district of Weston-super-Mare, but some years ago resigned this appointment with a superannuation allowance. He was honorary surgeon to the Weston-super-Mare Hospital and Dispensary, certifying factory surgeon, and Admiralty surgeon and agent. Mr. Hitchins was one of the oldest and most esteemed residents of Weston and the senior medical practitioner of the town. He was extremely popular, and was a fine specimen of the old-fashioned medical practitioner, and his wonderful vigour made it difficult to realise that he had attained such a great age, for until a few weeks ago he was attending to his professional duties.

Medical News.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—At a meeting of the Council of the Royal College of Surgeons of England on Oct. 12th the under-mentioned diplomas were conferred upon the following candidates, who have now complied with the respective by-laws:—

F.R.C.S.—Anandrai Keshavlal Dalal, L.M.S. Bombay, L.R.C.P., M.R.C.S., Bombay University, King's College and Middlesex Hospitals; and Herbert Henry Sampson, M.B., Ch.B. Birm., L.R.C.P., M.R.C.S., Birmingham University and London Hospital.

M.R.C.S.—John Bruce Baird, B.Sc., M.B., Ch.B. Glasg., Glasgow University and King's College Hospital; Robert Coltart Harkness, M.B., Ch.B. Edin., Edinburgh University; Victor Stanley Kaufman, M.B. Toronto, Toronto University and London Hospital; and Henry Goulding Rice, B.A. Cantab., Cambridge University and Guy's Hospital.

L.D.S.—Henry Kinnear Ovey, Charing Cross and Royal Dental Hospitals; and John Herbert Wiles, Guy's Hospital.

UNIVERSITY OF CAMBRIDGE.—At the examination in sanitary science held recently the following candidates satisfied the examiners in both parts of the examination:—

William McEntire Clendinnen, James Frederick Corson, Douglas Vernon Cow (Trinity), Albert Victor Craig, Frederick Douglas Crosthwaite, Peter Paul Debono, Thomas Scarbrough Dudding, *Robert Hankinson Williams Fisher (Emmanuel), Kenneth Fraser, †John Gilmour, †Alexander Campbell Nicholson McHattie, Ada McLaren, William Nicoll, Ardeshir Beheramshah Pestonji, Ralph Montgomery Fullerton Picken, Mary Janet Pirret, Laura Gertrude Powell, Reginald Fawcett Priestley (Caius), Leethem Reynolds (Trinity), Ernest Theophilus Roberts, †Berkeley Hope Robertson, James Alexander Richard Thompson, George Henry Hitchcock Waylen (King's), Ernest Alfred Freear Wilkes, Lisette Anne Macdonald Wilson, and Frederick Lindsay Woods.

* Distinction in bacteriology. † Distinction in hygiene.

FOREIGN UNIVERSITY INTELLIGENCE.—*Baltimore* (*University of Maryland*): Dr. G. Timberlake has been appointed Professor of Genito-Urinary Diseases.—*Berlin:* Dr. Walter Albrecht of Tübingen has been appointed *Oberarzt* of the Laryngological and Otological Clinic of the Charité under Professor G. Killian.—*Breslau:* Dr. Carl Bruck, *privat-docent* of Dermatology, Dr. Curt Zeigler, *privat docent* of Medicine, Dr. Friedrich Strecker, *privat-docent* of Anatomy and Biology, Dr. Heinrich Sachs, *privat-docent* of Neurology, and Dr. August Most, *privat-docent* of Surgery, have been granted the title of Professor.—*Lemberg:* Dr. Raczynski, Extraordinary Professor of Pædiatry, has been promoted to Ordinary Professor.—*Louisville:* Dr. W. B Doherty, Lecturer, has been promoted to the chair of Midwifery in succession to Dr. H. E. Tuley, resigned.—*Marburg:* Dr. F. König of Greifswald has been offered the chair of Surgery in succession to Dr. P. L. Friedrich, who goes to Königsberg.—*Moscow:* Dr. N. A. Savelyeff, Professor in Dorpat (Iurieff), has been appointed Professor of Therapeutics.—*Münster:* Dr. Eugen Kurz, one of the Prosectors in the Anatomical Institute, has been offered the position of Director of the Anatomical Department of the Shanghai German Medical School in succession to Dr. Ammann.—*Palermo:* Dr. S. Diliberti Herbin has been recognised as *privat-docent* of Surgical Anatomy and Operations; Dr. G. Caramanna as *privat-docent* of Neurology and Psychology; and Dr. G. Spotu as *privat-docent* of Ophthalmology.—*Parma:* Dr. E. Cecchetto has been recognised as *privat-docent* of Ophthalmology; and Dr. J. Bocchia as *privat-docent* of Hygiene and Sanitary Police.—*Pavia:* Dr. C. Barazzoni has been recognised as *privat-docent* of Internal Pathology; and Dr. G. Morone as *privat-docent* of External Pathology.—*Prague* (*German University*): Dr. Wilhelm Wiechowski, Extraordinary Professor in Vienna, has been appointed to the chair of Pharmacology in succession to Dr. J. Pohl, who is migrating to Breslau.—*Rome:* Dr. F. Fulci has been recognised as *privat-docent* of Pathological Anatomy; Dr. P. Ciuffini and Dr. F. Felici as *privat-docenten* of Otology and Laryngology; and Dr. D. Valebona as *privat-docent* of Physio-therapeutics.—*St. Louis* (*Washington University*): Dr. Roger S. Morris, Adjunct Professor in Johns Hopkins University, has been appointed Adjunct Professor of Medicine.—*Saratoff:* Dr. A. Bogomoletz of Odessa has been appointed Professor of General Pathology.—*Sienna:* Dr. F. Pancrazio has been recognised as *privat-docent* of Internal Pathology.—*Würzburg:* Dr. G. Hotz, *privat-docent* of Surgery, has been granted the title of Extraordinary Professor.

CENTRAL MIDWIVES BOARD.—A meeting of the Central Midwives Board was held at Caxton House, Westminster, on Oct. 12th, with Sir Francis Champneys in the chair. A letter was considered from Adeline Margaret Taylor, a midwife, as to a letter received by her from the honorary secretary of the Enfield Medico-Ethical Society, informing her that the society had unanimously agreed that a midwife calling in a medical practitioner in any stage of a confinement must guarantee a fee of not less than a guinea and a half, and that the case must be taken over entirely by the doctor. The secretary reported that he had forwarded a copy of the letter of the Enfield Medico-Ethical Society to the Privy Council, and the reply of the clerk of the Council was considered. The Board decided that a copy of Sir Almeric FitzRoy's letter (in which he observes that "the medical interests of the society in question appear to be more prominent than its ethical pretensions, and that in my opinion the correspondence discloses a most improper imposition on the midwife, and one which it is her duty to ignore") be sent to Adeline Margaret Taylor, and that she be informed that the Board has no control over the medical profession, but that if she does her duty under the rules she will discharge the responsibility that attaches to her. The Board, however, regrets that the Government has not yet made provision in such cases. A letter was considered from the deputy clerk of the Privy Council transmitting a copy of a letter addressed to the Home Secretary by Mr. A. Shaw of Bromyard with regard to the case of an uncertified woman practising as a midwife. The Board directed that it be pointed out to the clerk of the Council that the Board has no jurisdiction over uncertified women, the duty of prosecuting whom for a breach of Section 1 of the Midwives Act devolves on the local supervising authority under Section 13 of the Act. A letter was considered from the town clerk of St. Helens, inquiring as to the power of the local supervising authority to make a rule prohibiting a midwife from laying-out a dead body. The Board directed that inquiry be made of the Privy Council as to the power of the local supervising authority to frame a rule as indicated by Rule E. 17 (*b*). A letter was considered from the medical officer of health of Bradford, suggesting that the Board should prescribe a temperature chart for the use of midwives. A letter was considered from Miss Wooldridge, one of the inspectors of midwives for Staffordshire, on the same subject. The Board

decided that the medical officer of health of Bradford be informed that the Board does not propose to prescribe a temperature chart, suitable books for the purpose being already in circulation; and that Miss Wooldridge be informed that the temperature should not be entered in the register, but in a separate book, as directed by the local supervising authority. A discussion took place on a letter from a teaching institution, asking if the training of an epileptic candidate for midwifery should be continued. The Board expressed the opinion that a woman subject to epileptic fits is not competent to practise as a midwife.

LEWES VICTORIA HOSPITAL.—The new Lewes Victoria Hospital, which was opened early last year, is now entirely free of debt. When the report and balance-sheet were drafted for presentation at the annual meeting of donors and subscribers on Oct. 10th there was a debt on the building fund of £246 16*s.* 3*d.*, and on the furnishing fund of £46 1*s.* 7*d.*, but when the meeting-time came the satisfactory announcement was made that with the aid of an unexpected donation and the assistance of other friends the debts had been liquidated. In connexion with the hospital a new dispensary has been opened on modern lines.

THE LONDON HOSPITAL MEDICAL COLLEGE.—The following entrance scholarships have been awarded: Price Entrance Scholarship in Science, value £120, H. W. L. Molesworth; Entrance Science Scholarship, value £60, D. Valentine; Entrance Science Scholarship, value £35, A. G. Harsant; Epsom Scholarship, value £126, A. Alexander; Price Scholarship in Anatomy and Physiology (University Scholarship), value £60, L. P. Costabadie, B.A., Gonville and Caius College, Cambridge; Buxton Scholarship in Arts, value £30, C. A. Hutchinson; and Buxton Scholarship in Arts, value £20, C. O. Carter.

BRITISH MEDICAL BENEVOLENT FUND GUILD: GLASGOW BRANCH.—A branch of the British Medical Benevolent Fund Guild in Glasgow was formed on Oct. 14th at a drawing-room meeting held in Lady McCall Anderson's house, 6, University-gardens. Sir George Beatson presided, and there were present: Sir John Tweedy, London; Sir James and Lady Barr, Liverpool; Sir Hector Cameron, the Misses Turner, Edinburgh; Dr. May Thorne, London; and others. The chairman explained that it was not proposed to form a new society. All that they aimed at was to set on foot an auxiliary or adjunct institution to the British Medical Benevolent Fund. Dr. May Thorne explained the objects of the Guild, and said that the Guild was very anxious not merely to be a giver of doles and even sympathy, but to be a real help in advising and helping people to earn their own living. There was no doubt that the ordinary responsibilities of the upbringing and education of children by the general practitioner were greatly added to by the very small means that many of them had and by the uncertainty of those means. The doctor's bill was frequently the last to be paid. The British Medical Benevolent Fund for many years had been giving grants to medical practitioners, and where necessary to the wives and children and widows and children; but it became borne in on some that grants were not sufficient; that if a measure of personal service could be brought in it would be of infinite value. Therefore this hand-maid of the Fund—the Guild—was organised two years ago in order that the funds might really be more efficiently made use of than perhaps they had been in some cases in the past. The Guild consisted of members and associates, and its objects were to help the British Medical Benevolent Fund by obtaining additional subscribers to the Fund and making it more widely known, and to assist members of the medical profession, their wives and families, who were beneficiaries of the Fund. Lady Barr spoke of the formation of the Liverpool branch, which she said had now 120 members. Sir John Tweedy said that the British Medical Benevolent Fund was instituted in 1835, and since then about £72,000 had been distributed in annuities and £75,000 in grants. During these years there had been 530 annuitants, and there were 131 persons at present on the list. 8330 cases had been relieved by grants. It was agreed to form a branch of the Guild, and on the motion of Sir Hector Cameron the following ladies were elected a committee: Lady MacAlister, Lady McCall Anderson, Mrs. Bryce, Mrs. Maitland Ramsay, Mrs. Ranton, Mrs. Grant Andrew, Mrs. Mackintosh, Mrs. John Cowan, Mrs. William McLennan, Mrs. Ebenezer Duncan, with Miss Alice McCall Anderson and Miss Beatson as joint secretaries. Sir James Barr moved a vote of thanks to the speaker, and Mrs. Maitland Ramsay proposed a vote of thanks to the chairman.

THE London Vegetarian Association will hold a reception illustrated with an "unfired food demonstration," arranged by Mrs. Spencer, in the Board Room of the Memorial Hall, Farringdon-street, London, on Thursday, Oct. 26th, at 8 P.M., with Dr. Knaggs in the chair. Mr. Charles Spencer will speak on "The Diet of the Coming Race."

CENTRAL LONDON THROAT AND EAR HOSPITAL.—The inaugural lecture of the winter session at the Central London Throat and Ear Hospital will be delivered by Dr. P. Watson-Williams on Friday, Oct. 27th, at 3 o'clock precisely. On the same evening the annual dinner of the medical staff will take place at the Trocadéro, when Dr. Andrew Wylie will preside.

INCORPORATED ASSOCIATION OF HOSPITAL OFFICERS.—The ninth annual dinner of the association will be held on Saturday, Nov. 4th, at 7 for 7.30 o'clock, at the Holborn Restaurant, High Holborn, W.C. The President of the association, Mr. Richard Kershaw, will be in the chair. Colonel Sir John Young, C.V.O., will be the guest of the evening. Application for tickets should be made to the honorary secretaries, 32, Sackville-street, London, W.

THE ROYAL SANITARY INSTITUTE: SOUTH AFRICAN BRANCH.—The South African Branch of the Royal Sanitary Institute is arranging to hold a congress in Cape Town on Nov. 9th, 10th, and 11th. This is the first sanitary congress to be held in British South Africa, and it is hoped that a large number of delegates will be sent by the municipalities and other authorities interested in sanitation. Among the subjects set down for discussion are: the disposal of sewage, the prevention of tuberculosis, the inspection of food, milk-supplies, and school hygiene. Papers will also be read dealing with other aspects of public health work. The South African Branch, which has only recently been established by the Royal Sanitary Institute, will no doubt have a beneficial effect in the development of public health administration in the Union of South Africa. The honorary secretary to the branch is Dr. A. Jasper Anderson, the medical officer of health of Cape Town.

ROYAL COLLEGE OF SURGEONS IN IRELAND.—The winter session was opened on Oct. 16th, when the prizes of the previous session were distributed by the President, Mr. Robert H. Woods, as follows:—Barker Anatomical Prize, £31 10*s.*, Miss Eleanor Taylor; special prize (£15 15*s.*), T. Mulcahy. Carmichael Scholarship, £15, E. Connell. Mayne Scholarship, £8, J. T. Duncan. Gold Medal in Operative Surgery, J. T. Duncan; Silver Medal, H. J. Burke. Stoney Memorial Gold Medal in Anatomy, M. Shipsey. Practical Histology: G. M. C. Powell, first prize (£2) and medal; W. P. Cooney, second prize (£1) and certificate. Practical Chemistry: V. A. Power, first prize (£2) and medal; M. Moran, second prize (£1) and certificate. Public Health and Forensic Medicine: G. N. Smyth, first prize (£2) and medal; G. E. Pepper, second prize (£1) and certificate. Materia Medica: G. N. Smyth, first prize (£2) and medal; E. Connell, second prize (£1) and certificate. Biology: N. E. Stephens, first prize (£2) and medal; K. Elms and L. M. Rowlette (equal), second prize (£1) and certificate. Systematic Anatomy: W. H. Carden, first prize (£2) and medal; L. S. O'Grady and R. P. Weldon (equal), second prize (£1) and certificate. Surface and Topographical Anatomy: W. P. Cooney, first prize (£2) and medal; A. Merrin, second prize (£1) and certificate. Practical Anatomy: First year, A. F. Carbury, first prize (£2) and medal; P. J. Polson, second prize (£1) and certificate; second year, M. Shipsey, first prize (£2) and medal; W. Morrow, second prize (£1) and certificate. Practice of Medicine: M. J. Hillery, first prize (£2) and medal; Vernon J. White, second prize (£1) and certificate. Surgery: M. J. Hillery, first prize (£2) and medal; Vernon J. White, second prize (£1) and certificate. Midwifery: M. J. Hillery, first prize (£2) and medal; Vernon J. White, second prize (£1) and certificate. Physiology: W. H. Carden, first prize (£2) and medal; R. P. Weldon, second prize (£1) and certificate. Chemistry: L. M. Rowlette, first prize (£2) and medal; P. J. Polson, second prize (£1) and certificate.

Pathology: G. N. Smyth, first prize (£2) and medal; G. E. Pepper, second prize (£1) and certificate. Physics: J. W. E. Graham, first prize (£2) and medal; J. C. Fergusson, second prize (£1) and certificate.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.—At the conclusion of the Harveian Oration on Oct. 18th the President of the College presented the Baly medal to Professor W. D. Halliburton, M.D., and the Bisset Hawkins medal to Dr. Clement Dukes.

MIDDLESEX HOSPITAL MEDICAL SCHOOL.—The following scholarships were awarded at the opening of the winter session:—First entrance scholarship (£100), W. T. Warwick; second entrance scholarship (£50), J. K. Muir; third entrance scholarship (£25), W. L. Thomas; University scholarship (£50), A. T. Edwards, St. John's, Cambridge; and Freer Lucas scholarship (Epsom College) (£126), E. St. Clair Gainer.

DEATH OF DR. LEONARD KEATLEY YELF.—Dr. L. K. Yelf was born at Ryde, Isle of Wight, in the year 1828, and was apprenticed in the old-fashioned way at Leamington before pursuing his medical studies at King's College Hospital. He became M.R.C.S. Eng. and L.S.A. in 1852, and then practised for a short time at Melbourne, but returned from Australia in 1856. He then took the degree of M.D. of St. Andrews University, and settled down to practice at Moreton-in-Marsh. In the Cotswold district he worked hard and unceasingly for close on 40 years, and was much esteemed by his patients of all classes. He was particularly kind to the poor, who regarded him as a friend. He took an active part in founding the Moreton Cottage Hospital, of which institution he was surgeon till his retirement in 1895, when he was made consulting surgeon. At the same time he was presented with a silver bowl and purse of money, this mark of appreciation having been subscribed for by his patients and friends. He afterwards resided at Boscombe and latterly at Bransgore, Christchurch, enjoying a well-earned rest. He died on Oct. 3rd from cerebral hæmorrhage.

SOCIETY FOR RELIEF OF WIDOWS AND ORPHANS OF MEDICAL MEN.—A quarterly court of the directors was held on Oct. 11th, Dr. Rigden, Vice-President, being in the chair. Fourteen members were present. The court opened by the chairman referring to the great loss the society had sustained by the death of its president, Dr. George Fielding Blandford, who was elected a member in 1869, and who had always taken the keenest interest in its work. A formal vote of condolence was passed to Dr. Blandford's widow and family. The chairman then moved a vote of congratulation to Sir Thomas B. Crosby, one of the vice-presidents of the society, on his being selected to hold the high office of Lord Mayor of London. This was carried. Four gentlemen were elected members of the society. The acting treasurer reported that the funds of the society would allow of some increase of the grants being made, and brought forward two alternative schemes. It was eventually resolved that in future the yearly grants to orphans be £25 instead of £15. The sum of £515 was voted as a Christmas present to the annuitants of the charity—each widow to receive £10, each orphan £3, and each orphan on the Copeland Fund £5. Relief is only granted to the widows and orphans of deceased members. Any registered medical practitioner who at the time of his election is resident within a 20-mile radius from Charing Cross is eligible for membership. Full particulars may be obtained from the secretary at the offices of the society, 11, Chandos-street, Cavendish-square, W.

BOOKS, ETC., RECEIVED.

CHURCHILL, J. AND A., London.
Domestic Hygiene for Nurses, with so much of Physics and Chemistry as are necessary to the reasonable Understanding thereof. By Fred. J. Smith, M.D., F.R.C.P., Physician to the London Hospital and Examiner in Elementary Hygiene to the Nursing Probations. Price 2s. 6d. net.
A Handbook of Physics and Chemistry. Adapted to the Requirements of the First Examination of the Conjoint Examining Board of the Royal Colleges of Physicians and Surgeons, and also for General Use. By Herbert E. Corbin, B.Sc. Lond., M.R.C.S., L.R.C.P., D.P.H., Medical Officer of Health, Stockport, and Archibald M. Stewart, M.A., T.C.D., B.Sc. Lond., Headmaster of Alresford Grammar School. Fourth edition. Price 7s. 6d. net.

CORNISH BROTHERS, LIMITED, 37, New-street, Birmingham.
Plague at Home and Abroad. Being the Annual Public Lecture on "The Laws of Health," delivered at the Midland Institute, Birmingham, October 6th, 1911. By David Fraser Harris, M.D., D.Sc., B.Sc. Lond., F.R.S.E., Professor of Physiology in the University of Halifax, Nova Scotia. Price 3d. net.
A Miscellany of Verse. By Joseph J. Mooney. Price 2s. 6d. net.

COX, HORACE, "Field" Office, Windsor House, Bream's Buildings, London, E.C.
Sugar Beet, Some Facts and Some Illusions. A Study in Rural Therapeutics. By "Home Counties" (J. W. Robertson-Scott). Price 6s. net.

FROWDE, HENRY, AND HODDER AND STOUGHTON, London.
A Manual of Fevers. By Claude Buchanan Ker, M.D. Ed., F.R.C.P. Ed., Medical Superintendent, City Hospital, Edinburgh. Price 7s. 6d. net.
Clinical Surgery. By C. B. Lockwood, Surgeon to St. Bartholomew's Hospital. Second edition. Price 5s. net.
Manual of Physiology. For Students and Practitioners. By H. Willoughby Lyle, M.D., B.S. Lond., F.R.C.S. Eng., Assistant Ophthalmic Surgeon to King's College Hospital. Price 15s. net.
Tuberculous Diseases of Bones and Joints, their Pathology, Symptoms, and Treatment. By Sir W. Watson Cheyne, Bart., C.B., F.R.S., F.R.C.S., D.Sc., LL.D., &c., Professor of Clinical Surgery at King's College Hospital. Second edition. Price 16s. net.

GREEN, WILLIAM, AND SONS, Edinburgh and London.
Reproduction in the Human Female. The Uterine Mucosa in the Resting, Menstrual, and Pregnant States, and the Function of the Decidua; incorporating an Account of an Early Human Ovum. By James Young, M.D., F.R.C.S. Ed., Physician to the Lauriston Pre-Maternity Home. Price 21s. net.

KEGAN PAUL, TRENCH, TRÜBNER, AND CO., LIMITED, London.
Where Do We Come from? Is Darwin Correct? A Philosophical and Critical Study of Darwin's Theory of "Natural Selection." By Herbert Morse, B.A. Oxon., and Lincoln's Inn, Barrister-at-Law. Price 7s. 6d. net.

KELLY, CHARLES H., 25-35, City-road, and 26, Paternoster-row, London, E.C.
National Health Manuals. School Life. Edited by T. N. Kelynack, M.D. Price, limp cloth, 1s. net.; cloth boards, 1s. 6d. net.

A German Invasion and the Real German Peril. By Henry Sewill. Reprinted with permission from "The Westminster Review," August, 1911. Price 6d.

LANE, JOHN, The Bodley Head, Vigo-street, London, W.
The Dempsey Diamonds. By Allen Arnot. Price 6s.

LONGMANS, GREEN, AND CO., London, New York, Bombay, and Calcutta.
Dental Disease in its Relation to General Medicine. By J. F. Colyer, L.R.C.P., M.R.C.S., L.D.S., Dental Surgeon to Charing Cross Hospital and the Royal Dental Hospital, with the Assistance of Stanley Colyer, M.D. Lond., M.R.C.P., D.P.H. Price 4s. 6d. net.

ROUTLEDGE, GEORGE, AND SONS, LIMITED, London. (DUTTON, E. P., AND CO., New York.)
Medical Education and Infant Feeding. An Impeachment and a Suggested Remedy. By D. Hastings Young, M.B., Ch.M. Edin. Price 2s. 6d.

SEELEY, SERVICE, AND CO., LIMITED, 38, Great Russell-street, London.
Medical Science of To-Day. A Popular Account of the More Recent Developments in Medicine and Surgery. By Willmott Evans, M.D., B.S., B.Sc. Lond., F.R.C.S. Eng., Surgeon to the Royal Free Hospital and Surgeon to the Hospital for Diseases of the Skin, Blackfriars. Price 5s. net.

STATE GAZETTE PUBLISHING CO., Printers, Trenton, N.J., U.S.A.
Thirty-fourth Annual Report of the Board of Health of the State of New Jersey, 1910, and Report of the Bureau of Vital Statistics. Price not stated.

THIN, JAMES, 54, 55, and 56, South Bridge, Edinburgh.
Practical Chemistry for Medical Students. By Alexander Charles Cumming, D.Sc., Lecturer on Chemistry in the University of Edinburgh. With Preface by Professor James Walker. Price not stated.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.*

ATKIN, E. E., M.B. Cantab., has been appointed Assistant Bacteriologist at the Lister Institute of Preventive Medicine.

BRAMWELL, BYROM, M.D. Edin., has been appointed Physician to Chalmers' Hospital, Edinburgh.

COOPER, W. R., M.R.C.S., L.R.C.P. Lond., has been appointed Clinical Assistant to the Samaritan Free Hospital.

DEWAR, ALLAN, M.R.C.S., L.R.C.P. Lond., has been appointed Senior House Surgeon at the Royal Albert Hospital, Devonport.

FUNK, CASIMIR, has been appointed a Research Scholar at the Lister Institute of Preventive Medicine.

HARDENBERG, E. J. F., M.R.C.S., L.R.C.P. Lond., has been appointed Surgeon to the "N" Division Metropolitan Police at Chingford.

HOLDICH-LEICESTER, J. C., Major, I.M.S., has been appointed Clinical Assistant to the Samaritan Free Hospital.

ILLIUS, H. WARWICK, Captain, I.M.S., has been appointed Clinical Assistant to the Samaritan Free Hospital.

MACFARLANE, W. D., M.B., M.S. Glasg., has been appointed to the Chair of Midwifery and Gynæcology at Anderson's College Medical School, Glasgow.

MOLONEY, M. F., M.B.N.U.I., has been appointed Coroner for the County of Waterford, and assigned to the Western District.

MUNRO, H. L., M.D. Edin., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Beverley District of the county of Yorks, East Riding.

NORRIS, A. H., M.R.C.S., L.R.C.P. Lond., D.P.H., has been appointed Assistant School Medical Officer for the Berkshire County Education Committee.

O'CONNOR, S. V., L.A.H. Dub., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Crossabeg District of the county of Wexford.

RANSON, WILSON, L.R.C.P. Edin., F.R.C.S. Edin., L.F.P.S. Glasg., has been appointed Medical Officer of Health to the Beverley Rural District Council.

RAY, W., M.R.C.S., L.R.C.P. Lond., has been appointed Assistant Bacteriologist at the Lister Institute of Preventive Medicine.

REID, R., L.R.C.P. & S. Edin., L.F.P.S. Glasg., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Whitehouse District of the county of Antrim.

WHEELER, H. Q. O., L.R.C.P. & S. Irel., has been appointed Senior House Surgeon at the Borough Hospital, Birkenhead.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

BANGOR, CARNARVONSHIRE AND ANGLESEY INFIRMARY.—House Surgeon. Salary £100 per annum, with board, washing, and lodging.

BATH, EASTERN DISPENSARY.—Resident Medical Practitioner. Salary £130 per annum, with apartments, coals, gas, &c.

BIRKENHEAD BOROUGH HOSPITAL.—Junior Resident House Surgeon. Salary £80 per annum, with board and washing.

BIRMINGHAM CITY ASYLUM, Winson Green.—Junior Assistant Medical Officer. Salary £150 per annum, with board, laundry, &c.

BIRMINGHAM EAR AND THROAT HOSPITAL, Edmund-street.—House Surgeon for six months. Salary at rate of £70 per annum, with board, lodging, and washing.

BRISTOL GENERAL HOSPITAL.—House Surgeon for six months. Salary £80 per annum, with board, residence, &c.

BRISTOL ROYAL INFIRMARY.—Throat, Nose, and Ear House Surgeon. Salary £75 per annum, with board, apartments, and washing.

BURY INFIRMARY.—Junior House Surgeon. Salary £80 per annum, with board, residence, and laundry.

BUXTON, DERBYSHIRE, DEVONSHIRE HOSPITAL.—Assistant House Surgeon. Salary £100 per annum, with apartments, board, and laundry.

CAMBRIDGE, ADDENBROOKE'S HOSPITAL.—Second House Surgeon for nine months. Salary £80 per annum, with board, residence, and laundry.

CARDIFF INFIRMARY (GENERAL HOSPITAL).—House Surgeon for six months. Salary £30, with residence, board, and laundry.

COBHAM, SURREY, SCHIFF HOME FOR SURGICAL CONVALESCENTS.—Resident Surgical Officer for six months. Salary £100.

CROYDON GENERAL HOSPITAL.—Junior House Surgeon. Salary £75 per annum, with board, laundry, and residence.

DENBIGH, DENBIGHSHIRE INFIRMARY.—House Surgeon. Salary £100 per annum, with board, residence, and washing.

DEVONPORT, ROYAL ALBERT HOSPITAL.—Assistant House Surgeon, unmarried, for six months. Salary at rate of £75 per annum, with board, apartments, laundry, &c.

DUDLEY, GUEST HOSPITAL.—Assistant House Surgeon for six months. Salary £75 per annum, with residence, board, and washing.

ENNISKILLEN, FERMANAGH COUNTY HOSPITAL.—House Surgeon. Salary £72 per annum.

EVELINA HOSPITAL FOR SICK CHILDREN, Southwark, London, S.E.—House Physician. Salary at rate of £80 per annum, with board, residence, and washing.

EXETER, ROYAL DEVON AND EXETER HOSPITAL.—House Physician and Assistant House Surgeon for six months. Salary of former at rate of £90 per annum, and of latter at rate of £80 per annum.

GLAMORGAN COUNTY COUNCIL.—Medical Officer for Inspection of School Children. Salary £250 per annum.

GLOUCESTER COUNTY ASYLUMS.—Assistant Medical Officer, unmarried. Salary £150 per annum, with rooms, rations, laundry, and attendance.

HAMILTON ISOLATION HOSPITAL, near Motherwell.—Resident Physician-Superintendent. Salary £200 per annum, with board, &c.

HOLT, NORFOLK, GRESHAM'S SCHOOL.—Medical Officer. Salary £250 per annum.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street, London, W.C.—Assistant Casualty Medical Officer, unmarried, for six months. Salary £30, with board, residence, &c.

HUDDERSFIELD ROYAL INFIRMARY.—Junior Assistant House Surgeon. Salary £60 per annum, with board, residence, and washing.

HULL ROYAL INFIRMARY.—Two Assistant House Surgeons. Salary at rate of £60 per annum, with board and lodging.

LEICESTER INFIRMARY.—House Surgeon. Salary at rate of £120 per annum, with board, apartments, and washing.

LINCOLN COUNTY HOSPITAL.—Junior House Surgeon, unmarried, for six months. Salary at rate of £75 per annum, with board, residence, and washing.

LINCOLN MENTAL HOSPITAL, The Lawn, Lincoln.—Assistant Medical Officer, unmarried. Salary £150 per annum, with board, &c.

LIVERPOOL, CANCER RESEARCH LABORATORY, The University.—Assistant. Salary £150 per annum.

LIVERPOOL EYE AND EAR INFIRMARY, Myrtle-street.—Honorary Assistant Surgeon.

MANCHESTER, CITY OF.—Registered Medical Practitioner. Salary £250 per annum.

MANCHESTER NORTHERN HOSPITAL FOR WOMEN AND CHILDREN, Parkplace, Cheetham Hill-road.—House Surgeon. Salary £100 per annum, with apartments and board.

MELROSE, ROXBURGH DISTRICT ASYLUM.—Assistant Medical Officer. Salary £160 per annum, with board, lodging, and washing.

NAPSBURY, ST. ALBANS, MIDDLESEX COUNTY ASYLUM.—Assistant Medical Officer. Salary £160 per annum, with board, lodging, washing, and attendance.

OLDHAM ROYAL INFIRMARY.—Third House Surgeon for six months. Salary £80 per annum, with board, residence, and laundry.

OLDHAM UNION WORKHOUSE.—Resident Assistant Medical Officer.

PADDINGTON GREEN CHILDREN'S HOSPITAL, London, W.—Clinical Assistants.

POPLAR AND STEPNEY SICK ASYLUM, Bromley, Middlesex, E.—Third Assistant Medical Officer. Salary £120 per annum, with rations, apartments, and washing.

POPLAR HOSPITAL FOR ACCIDENTS, Poplar, E.—Senior House Surgeon. Salary at rate of £135 per annum, with board and residence.

PORTSMOUTH, ROYAL PORTSMOUTH HOSPITAL.—House Physician for six months. Salary £75 per annum, with board, &c.

PORTSMOUTH WORKHOUSE INFIRMARY, WORKHOUSE, AND CHILDREN'S HOME.—Second Assistant Resident Medical Officer. Salary £120 per annum, with apartments, rations, &c.

RICHMOND, SURREY, ROYAL HOSPITAL.—Assistant House Surgeon. Salary £70 per annum, with board and apartments.

ROCHDALE INFIRMARY.—House Surgeon, unmarried. Salary £100 per annum, with board, residence, and laundry.

ROUSAY AND EGILSHAY, PARISH OF.—Resident Medical Officer. Salary £71 per annum.

ROYAL NAVAL MEDICAL SERVICE.—Fifteen Commissions.

ROYAL WATERLOO HOSPITAL FOR CHILDREN AND WOMEN.—Honorary Dental Surgeon.

ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN, 49, Leicester-square, W.C.—Honorary Vaccine-Therapeutist.

ST. MARYLEBONE GENERAL DISPENSARY, 77, Welbeck-street, Cavendish-square, W.—Honorary Surgeon. Also Resident Medical Officer. Salary £150 per annum, with apartments, attendance, coals, and light.

SHEFFIELD ROYAL INFIRMARY.—Three Junior Resident Medical Officers. Salaries £60 to £65 per annum.

STAFFORD, STAFFORDSHIRE GENERAL INFIRMARY.—House Physician. Salary £82 per annum, with board, residence, and laundry.

SURREY COUNTY COUNCIL.—Assistant Medical Officer for Inspection of School Children. Salary £250 per annum.

SWANSEA EDUCATION COMMITTEE.—Assistant School Medical Officers (one Male and one Female). Salaries £250 each per annum.

WALSALL AND DISTRICT HOSPITAL.—House Physician and Casualty Officer. Salary £80 per annum, with board, residence, and laundry.

WESTERN GENERAL DISPENSARY, Marylebone-road, N.W.—Junior House Surgeon. Salary at rate of £80 per annum, with board, residence, and washing. Also Honorary Ophthalmic Surgeon.

WESTON-SUPER-MARE HOSPITAL.—House Surgeon, unmarried. Salary £100 per annum, with board and residence.

WESTMINSTER HOSPITAL (opposite Westminster Abbey).—Assistant House Physician for two months, non-resident, but board provided.

WIGAN, ROYAL ALBERT EDWARD INFIRMARY.—Junior House Surgeon. Salary £100 per annum, with rations, washing, and apartments.

WINCHESTER, ROYAL HAMPSHIRE COUNTY HOSPITAL.—House Physician. Salary £80 per annum.

THE Chief Inspector of Factories, Home Office, London, S.W., gives notice of vacancies for Certifying Surgeons under the Factory and Workshop Act at Ramsgate, in the county of Kent; at Workington, in the county of Cumberland; and at Weston-super-Mare, in the county of Somerset.

Births, Marriages, and Deaths.

BIRTHS.

FLETCHER.—On Oct. 10th, at Haverstock-hill, the wife of N. Corbet Fletcher, M.B., B.C. Cantab., M.R.C.S., of a son.

FREEMAN.—On Oct. 11th, at Devonshire-place, W., the wife of Dr. John Freeman, of a daughter.

JEFFERISS.—On Oct. 8th, at Artois House, Chatham, the wife of Frederick B. Jefferiss, F.R.C.S., of a son.

MARRIAGES.

BIGGS—THOMPSON.—On Oct. 14th, at the Parish Church, Hampstead, Arthur Cecil Barker Biggs, M.R.C.S., L.R.C.P., to Dora Adeline Thompson, daughter of Archibald Thompson, Chesterford-gardens, N.W.

GRAY—MALLETT.—On Oct. 3rd, at St. Luke's Church, West Norwood, William Harrington Gray, M.R.C.S. Eng., L.R.C.P. Lond., to Lydia Alice Maud Mallett, of Wandsworth.

JAQUES—TATUM.—In Montreal, Canada, on Oct. 18th, 1911, by the Dean of Montreal, Mr. Frank H. Jaques, to Muriel, eldest daughter of H. T. Tatum, M.R.C.S.E., grand-daughter of the late Thomas Tatum, F.R.C.S.E., L.S.A., Consulting Surgeon to St. George's Hospital, London.

RIGBY—MACBETH.—On Oct. 12th, at All Souls', Langham-place, Hugh Mallinson Rigby, F.R.C.S., to Flora, daughter of Norman Macbeth, of Woldingham, Surrey.

WORTHINGTON—BANKART.—On Oct. 5th, at Exeter Cathedral, Robert Alfred Worthington, F.R.C.S., to Evelyn Marian, third daughter of the late James Bankart, F.R.C.S., and of Mrs. Bankart, of Exeter.

DEATHS.

HARGRAVE.—On Oct. 16th, at London Hospital, from pneumonia, Donald Herbert Hargrave, aged 19 years, the eldest son of Herbert J. Hargrave, M.B., C.M., of 32, Spital-square, Bishopsgate, E.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

COW-DUNG WASHING AND PLAGUE PREVENTION.

WITH reference to an annotation in THE LANCET of Sept. 30th, 1911, p. 968, Dr. C. N. Saldanha writes:—"I do not eulogise cow-dung floors. Concrete cement floors would be vastly preferable. But we have not got them and are not likely to have them for a long time yet for the general masses of the vast population of India. Finances forbid their adoption. Even concrete cement floors should be frequently cow-dung washed in India, especially during plague epidemics. What Dr. C. J. Martin means by a cow-dung floor is the common Indian mud floor which is cow-dunged over when first laid down. To keep it clean and habitable it requires to be frequently cow-dung washed. This is what is generally neglected in the Punjab and the North-West and other such plague provinces. Hindu conservatism in Madras and Eastern India generally secures indirectly much better attention to this most important sanitary rule. Dr. Martin's remarks on cow-dung floors, seemingly quoted in THE LANCET editorial as against my proposal, are in reality in support of it. The difference between the cow-dung floors of Dr. Martin and the cow-dunging, or cow-dung washing, of my proposal, and as understood by all the classes of the natives, is the difference between black boots or shoes and blackening boots or shoes. Black boots indicate the sort or colour of boots: blackening boots means the cleaning of them. Two different things altogether. Is this not so? Cow-dung washing destroys the rats' nests in the Indian rooms referred to by Dr. Martin, for the odds and ends in the room have to be removed. In fact, the room gets quite as empty as the builder first left it. Every bit of furniture goes out into the open central courtyard before the preparatory sweeping of the room for the cow-dunging commences at all. It is for this reason that the cow-dung-washing day is not in India a fixed day of the week. It comes once a week or once a year, or anywhere between the two periods, and in some families even oftener than once a week. But the day chosen is a bright sunny morning. This kills two birds with one stone. The housewife seeks a bright day to put out in the yard her sticks of furniture and odds and ends. She does not want them to get drenched with rain, but her main reason is that the cow-dung-washed room may get dried the quicker. Dry it she must and will. To obtain this end she must open wide all her doors and windows, which on other days is anathema maranatha. She thus unconsciously assists the scientific sanitarian on this one day. Now, among other things, I want to multiply the number of such days by increasing the frequency of cow-dung washing days. There is no other way of getting her to utilise the well-known effects of sunlight and free currents of air to devitalise B. pestis. Preaching is useless. Hearing is one thing and conviction is another. And one cannot convert all India to English and European notions of sanitation by simply preaching them. Actual demonstration is out of the question; one cannot get all India or any considerable fraction of it to attend to these demonstrations, least of all to believe in them. Sunlight and free ventilation, which are necessary for drying a cow-dunged room, also devitalise any tubercle bacilli that may have been present in the cow-dung used in washing the room. Free drying is a *sine qua non*. The housewife takes a pride in giving an even coat to the floor. Afterwards, and as a finishing process, the room is swept with a broom. Of course, if the floor is not quite dry this will cause smudges, and it will also stain the broom, both of which the housewife wants to avoid. Hence the great impetus to admit to-day heaven's gifts of light and air. The sweepings from the room must be burnt, as also the rag used in spreading the cow-dung. Cow-dung washing does not necessarily kill all the fleas caught in the process, but it facilitates their removal from the room. They get caught in the mucilage; it nets them. Some come off in the sweeping, which is therefore to be burnt, not thrown into the dustbin. As a precaution against conveyance of fleas from one floor to another, I have recommended a separate broom for each floor. Indian brooms only cost a farthing each, so it is a very inexpensive measure."

THE LATE DR. JOSEPH BELL.

"J. W. B." writes: "To many of those who studied at Edinburgh in the later 'seventies' and early 'eighties' of the last century Dr. Joseph Bell—or, as he was more familiarly called, Joe Bell—was one of the most attractive of the teachers of surgery, first in the Old and then in the New Infirmary. His ward visit was always a breezy one. Carrying a towel in his hand, he passed rapidly from bed to bed, getting information as to the progress of a patient, sometimes from the house surgeon sometimes from the staff nurse (there were no sisters then), sometimes from the patient, and sometimes from all three. In a few sentences we were told what had been the matter, when the operation had been done, and were assured that the man or the woman was getting along finely; very often, nearly always, the information was accompanied by a personal appeal for confirmation to the patient, and I remember wondering if any of Bell's cases ever went wrong. It was the early days of antiseptics, and the strength of the carbolic lotion employed would startle the present-day surgeon. With the really ill people he was very tender, gave us few details, and said to us almost in a whisper, 'Operate to-morrow; tell you all about it then.' Two or three of the cases requiring dressing were inspected, and three or four dressers putting on wool and bandages marked Dr. Bell's progress through his wards.

"But the ward visit was nothing in comparison to the out-patient clinic. It was there that Bell amazed us all, patients and students alike, with the rapidity of his diagnosis, with the brilliancy of some of his pieces of deductive reasoning, with the apparently irrelevant nature of some of the questions asked, and more particularly with the confident statements made as to the calling, habits, likes or dislikes, and place of birth of the men and women who came into the theatre and passed out again, often in the briefest space of time. Some of us explained it on the hypothesis that Dr. Bell got a sight of the out-patient clerk's note-book; but the patients who came up late spoiled that supposition. Occasionally, he condescended to tell us how he knew a policeman, a soldier, a sailor, or a cobbler, and then it all seemed uncommonly simple; but there were hundreds of little details which he seemed to obtain from nowhere, and about which he was silent. Of course, he occasionally made slips; once he asked a young girl when she came over from Ireland, to which she replied that this was the first time that she had left her native village in Ross-shire. Bell gave us the reason why he made that mistake, but I forget now what it was.

"One night I felt prompted to go to Bell's house to discuss a matter with him; I was shown into his library where he sat writing letters. He asked me to excuse him one minute as I had come a little earlier than he had intended. Presently he informed me that he had willed me to come along, but that I had come more quickly than he had expected. I had intended coming the previous evening, but had been prevented. Had I pressed this I suppose Bell would have retorted that on the previous evening he had not fully formulated his mental desire for my presence! On some similar occasion Dr. Bell told me of some curious experiences he had had. One of them, he thought, must have been the origin of Sherlock Holmes's discovery of the identity of a certain individual by reading the name on the lining of his hat. A patient had called one day to ask Dr. Bell's advice, but wished to remain *incognito*, and rather testily refused to give his name; Bell said nothing, but exchanging his ordinary sheet of notepaper for one of foolscap wrote his prescription in very small letters in the middle of it with the patient's name above it, and handed it to his would-be mysterious visitor. He had read his name on an article of his attire, which was not, however, the band of his hat.

"But there was another side of Joseph Bell's life, and to those who were present at that impressive funeral service in St. George's U. F. Church on Oct. 7th, Principal Whyte's marvellous prayer of thanksgiving to God for what Dr. Bell had been to so many patients, friends, students, and professional brethren must have seemed no idle words. Dr. Bell showed princely liberality when the occasion demanded; he was ready to give his surgical services for nothing when his patients were fighting hard to discharge all their obligations; he gave a helping hand to younger men climbing the ladder of professional success, and he did his kind things most unostentatiously, his kindest things almost as secrets from himself."

THE PRESERVATION OF VACCINE IN HOT COUNTRIES.

IN connexion with the annotation on this subject published in THE LANCET of Oct. 7th, p. 1027, we have received a reprint of a paper on the Effect of Desiccation on Calf Lymph, by Dr. F. R. Blaxall, which was included in the Reports of the Local Government Board, 1900–01, Appendix C, p. 664. He showed that the vaccine organism could stand desiccation for as long as four months without loss of vitality. He also suggested that the process of desiccation might prove to be of value in storing lymph and in transmitting it to hot countries. These observations were made several years prior to the publication of the paper referred to in our annotation.

ARMY AND NAVY MALE NURSES' COOPERATION.

THE offices of this institution are at 11A, Welbeck-street, Cavendish-square, W., and not at the address given in THE LANCET of Oct. 14th, p. 1077.

DANGERS OF A 50-MILE WALK.

THE pitiful condition of two competitors in a recent London to Brighton walking race should act as a warning to those who, without the necessary training and physique, may be induced to take part in such a severe trial of strength. The race took place under the auspices of the clerks of one of the London banks. Seventeen competitors entered and out of these ten were "timed in." Of the remaining seven two succeeded in getting within a quarter of a mile of their goal, where they struggled to a public seat in some pleasure-gardens, and there, in a state of absolute collapse, were found by a police officer. The seriousness of their condition was only too apparent, and the officer lost no time in procuring assistance and had them conveyed to the Royal Sussex County Hospital. Over-exertion had brought about their condition, and it was some hours before they were in a fit state to leave the institution. Except to those accustomed to long walks at frequent intervals, a journey on foot of this kind may lead to serious consequences.

ITALIAN CONVERSATION.

AN Italian medical man, practising in the South-West of London, would be glad to exchange conversation with some brother practitioner who wishes to learn Italian *free*. Our correspondent also speaks French fluently.

A CORRESPONDENT writes to point out one or two small inaccuracies in our obituary notice of Mr. L. S. Little in our last issue (p. 1108). It was in 1869 that Mr. Little went to China, and he lived in China for 30 years. He did not return direct to England, but in 1899 left China for South Africa.

Dr. W. L. Maccormac, the Infirmary, Balham, S.W., would be glad to learn of a suitable institution for a boy, aged 15, with chronic coarse choreiform movements and good intelligence.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

A DIARY OF CONGRESSES.

WE shall publish this diary from time to time that our readers may have under their hands the dates of the approaching scientific Congresses. It is unnecessary to issue the lists of all these functions week by week, and we propose to make only such gatherings as will occur in the immediate future the subject of regular announcement. The following Congresses, Conferences, and Exhibitions are announced for October, 1911:—

April-October.—Rome Exhibition (United Italy's Jubilee).
,, 29th-Oct. 26th (Turin).—International Exhibition.
May 3rd-Oct. 31st (Glasgow).—Scottish Exhibition.
,, 6th-Oct. 31st (Dresden).—International Hygiene Exhibition (British Section opened June 14th closed Oct. 16th).
,, 12th-Oct. 31st (London, Crystal Palace).—Festival of Empire Imperial Exhibition. (Profits to King Edward VII. Hospital Fund.)
,, 18th-October 21st (London, Shepherd's Bush).—Coronation Exhibition.
,, 23rd-Oct. 21st (London, Olympia).—Electrical Exhibition.

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic (2 P.M.), Hospital operations are performed daily.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will insure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free from THE LANCET Offices, have been reduced, and are now as follows:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 1 0	One Year	£1 5 0
Six Months	0 12 6	Six Months	0 14 0
Three Months	0 6 6	Three Months	0 7 0

(The rate for the United Kingdom will apply also to Medical Subordinates in India whose rates of pay, including allowances, is less than Rs.50 per month.)

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied.

Communications, Letters, &c., have been received from—

A Lecture
ON
ACUTE AND CHRONIC SUPPURATION OF THE NASAL ACCESSORY SINUSES:

ETIOLOGY, DIAGNOSIS, AND TREATMENT FROM THE POINT OF VIEW OF THE GENERAL PHYSICIAN AND SURGEON.

Delivered before the Medical Society of London on Oct. 23rd, 1911,

BY HERBERT TILLEY, B.S. LOND., F.R.C.S. ENG.,

SURGEON, EAR AND THROAT DEPARTMENT, UNIVERSITY COLLEGE HOSPITAL, LONDON.

[FOLLOWING some introductory remarks, Mr. Herbert Tilley pointed out that the mucous membrane of the nasal cavities was continuous with that lining the accessory sinuses (Fig. 1), and that acute inflammation of the former was practically always associated with a simultaneous inflammation of the accessory cavities, but a similar combination was less frequently met with in chronic suppurations because spontaneous resolution of acute inflammation occurred more readily in some of the sinuses than in others. The main anatomical features of the maxillary antrum were dwelt upon and were illustrated by diagrams, specimens, and lantern slides. Infection of the sinus by a diseased molar or bicuspid tooth was readily explained when the apex of the root reached close to the floor of the antrum, and this was frequently the case.]

ACUTE INFLAMMATION OF THE MAXILLARY ANTRUM.

In the majority of instances this condition is caused in one of two ways—(1) infection by way of the nose occurring in the course of acute specific fevers, and of this type influenza provides the greatest number of cases; (2) infection from the septic pulp of a diseased tooth. Facial erysipelas has been said to cause antral suppuration, but I am of opinion that repeated attacks of facial erysipelas are frequently due to infection by pyogenic organisms derived from suppuration of the antrum or other sinuses. Traumatisms account for a certain smaller number of acute antral inflammations, and here the careless use of the galvano-cautery or other intranasal operations, as well as unskilful or unclean dental extractions, add their undesirable quota.

Symptoms.—The symptoms vary according to the source of infection. Should the local inflammation complicate an acute systemic infection a considerable degree of pyrexia and severe pain in the cheek and its neighbourhood will be prominent symptoms. If the infection is caused by a tooth severe toothache and alveolar abscess might precede the antral symptoms and subside when the foul discharge from the nose takes place. Whatever the source of infection may be an examination of the corresponding nasal cavity will frequently reveal the presence of pus in the middle meatus.

Prognosis.—When the antral inflammation complicates a general systemic infection the inflammation of the mucous membrane is more general and intimate, and probably the patient's resistance is lower than when the suppuration is caused by a tooth, and hence the prognosis is less favourable from the point of view of rapid recovery in the former than in the latter and more local infection.

Treatment.—This will necessarily depend on the source of infection. If the antral inflammation complicates a constitutional infection—e.g., influenza—in addition to the treatment of the general disease every endeavour should be made to promote the spontaneous discharge of pus from the antrum. To this end the patient should rest in bed with the infected sinus uppermost, and every hour or two hours an application of equal parts of 10 per cent. cocaine and adrenalin chloride should be applied on cotton-wool mops to the middle meatal region. This will induce contraction and ischæmia of the mucosa and promote the free discharge of pus from the "ostium" in the middle meatus. Hot fomentations to the affected cheek and 10-grain doses of aspirin every four hours will go far to alleviate local pain and discomfort.

Should the symptoms persist in their severity the antrum should be punctured by trocar and cannula passed through the middle meatus or below the inferior turbinal and irrigated with warm normal saline solution or boric lotion; and I need scarcely say that the necessary manipulations can only be carried out with safety and a minimum of discomfort to the patient by those skilled in intranasal surgery. The irrigations may have to be repeated daily for a week or ten days.

When a diseased tooth is the cause of trouble it should be removed, the alveolus perforated, and a temporary alveolar plug inserted. The antrum can then be irrigated twice daily until the inflammation has subsided, when the alveolar passage may be allowed to close.

If bacteriological examination of the pus should prove that one organism is present or is in great predominance, an autogenous vaccine may assist and prove a valuable adjunct in treatment, but we must remember that, as a rule, acute cases tend to recover quickly and that a favourable result when a vaccine is used may be *post*, but not entirely *propter*, *hoc*.

CHRONIC ANTRAL SUPPURATION.

This is generally due to causes which hinder resolution of the acute inflammation and the most potent factors are those which obstruct free drainage such as an enlarged middle turbinal or deviation and irregularities of the nasal septum. In other instances the persistence of the discharge may be due to the virulence of the primary infection which has so damaged the lining membrane of the antrum that resolution has failed to take place. Furthermore, the type of organisms present may influence the chronicity of the inflammation (*vide infra*). Again, in the case of a diseased tooth the original focus of infection may remain.

I believe that sometimes chronic suppuration may slowly but ultimately graft itself on to a mucous membrane which has been in a state of simple chronic catarrh for a long while.

Symptoms.—These are: 1. A purulent or muco-purulent discharge from the nose nearly always described by the patient as "nasal catarrh." He may also complain of an offensive smell, or an unpleasant taste if the discharge passes backwards into the throat. 2. A certain amount of nasal obstruction caused by irritation and consequent swelling of the nasal mucosa. Not infrequently polypi are present in cases of long standing, and their presence indicates inflammation of the ethmoidal cells. 3. Headache, often supraorbital in position and not infrequently most marked in the earlier hours of the day.

Cough, liability to head colds, anæmia, indigestion, general debility, anorexia, mental depression are other symptoms which may be met with, and are possibly due to the irritation or absorption of the purulent discharge.

Finally, it has been shown that in certain cases of chronic antral suppuration there is a general contraction of the visual field. In other instances affections of the conjunctiva have been clearly traced to infection from the nose or antrum by way of the lacrymal canal and sac.

Bacteriology.—The very careful and exhaustive researches of Logan Turner and C. J. Lewis [1] have shown that four main types of cocci are generally responsible for chronic antral suppuration—viz., pneumococci, streptococci, staphylococci, and diplococci of the type of micrococcus catarrhalis, and that in recent cases the streptococci were virulent in 60 per cent., but only 30 per cent. were virulent in chronic suppuration.

Diagnosis.—Emphasis must be laid upon the importance of always suspecting sinus suppuration when a patient complains of *chronic nasal catarrh*, and especially so if pus is contained in the nasal mucus or if the handkerchief is found to be stained by it. A "morning headache" in a patient who has lived in malarial climates might easily lead to ineffectual dosing with quinine, when a little care might lead to the detection of antral suppuration. A positive diagnosis of the latter can be made by the detection of pus in the middle meatus, by transillumination of the antra or puncture of the sinus by a fine trocar passed through the inner antral wall—a proceeding which is almost painless when skilfully carried out.

Prognosis.—If the suppuration be of long standing it is improbable that any procedure short of operation will effect a cure, because the lining mucous membrane has undergone

[1] Edinburgh Medical Journal, April, 1910.

gross degenerative changes and excessive secretion has then become its normal function.

Cases of dental origin as a rule do better than those of intranasal origin, because the mucous membrane is less intimately infected.

When nasal polypi and therefore ethmoidal inflammation accompany antral suppuration the prognosis will be less favourable unless radical surgical measures are carried out.

Treatment.—Change of air, internal medication, and nasal washes are quite useless and are a waste of time and money, for they cannot remedy such a gross degeneration of the mucous membrane as is illustrated in the diagram taken from an ordinary case of chronic antral suppuration. Neither have I seen much success with vaccines, even when administered by the high priests of vaccine therapy. The infection is practically always a mixed one, there is a high degree of mucous membrane degeneracy, and drainage is nearly always obstructed. On the other hand, if only one organism be present or largely predominate, then vaccine therapy might be given a trial or used as an adjuvant in treatment.

Two methods for the cure of chronic antral suppuration may be considered. 1. Lavage or irrigation through the inner antral wall. By this means a small proportion of chronic cases may be cured, and bacteriology may give us a hint as to the type of case which may be benefited, for Lewis and Turner's researches show that "chronic cases in which no streptococcus pyogenes is found in the pus more readily respond to lavage than those in which the same organism is present," and also that lavage is more successful when a small number of lymphocytes are present than when an excess occurs. 2. Surgical measures. When these are contemplated the operator should endeavour (*a*) to remove diseased mucous membrane, and (*b*) to provide free, unhindered, spontaneous, and permanent drainage. To secure these ends two methods find favour. 1. A large opening is made, by way of the nose, in the inner antral wall after a preliminary removal of the anterior two-thirds of the inferior turbinal. Through such an opening daily irrigation may be practised by surgeon and patient until suppuration ceases. (Fig. 2.) 2. A similar opening in the inner antral wall, but the sinus is first entered through the canine fossa. (Fig. 3.) This is known as the Caldwell-Luc operation, and I believe it to be the better method because the surgeon can see into the affected region and remove only those parts which are diseased. Little recesses and pockets which serve as foci for suppuration are thus rendered visible, which is not the case when the antrum is opened by way of the nasal cavity. I have given each method a long and extensive trial, and am firmly convinced that the canine fossa route is the better for the large majority of chronic cases, while for a minority the intranasal route may be advisable and may be attended by completely successful results. The latter may be adopted when for any reason the more severe operation is contra-indicated, because the intranasal opening may quickly be made under local anæsthesia or a combination of local anæsthesia with that induced by ethyl chloride or nitrous oxide gas.

Alveolar drainage.—The attempt to cure chronic antral suppuration by drainage through the buccal socket of a bicuspid or molar tooth must be unsparingly condemned, because, in the great majority of cases, the suppuration is only relieved and not cured. The tube or plug, whether it be of gold or vulcanite, rarely drains the suppurating cavity, it allows all sorts of organisms and particles of food to gain access to the antrum from the buccal cavity, and the long-continued daily irrigation is an intolerable nuisance to the patient.

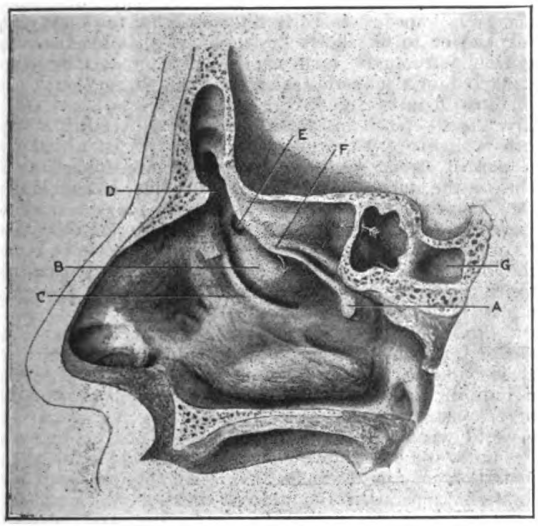
ETHMOIDAL SUPPURATION.

The diagrams, lantern slides, and specimens will show how very complicated is the gallery of cells which form the "lateral mass of the ethmoid." (Fig. 4.) We note its intimate relation to the frontal bone above, to the orbit on its outer side, the sphenoidal sinus behind, the inner and upper wall of the antrum below, and the close relation which its posterior group of cells may bear to the optic nerve. Not less important than these relations is that part of the ethmoid bone which forms the cribriform plate. I cannot dwell in any detail on the anatomy of this complicated bone, which varies to such a degree that it is almost impossible to speak of a normal type. Its cells frequently spread outwards below the frontal sinus till they reach the external angular process of the frontal bone, or backwards to the small wing of the sphenoid; posteriorly they are in close union with the sphenoidal cavity, and inferiorly they may spread outwards below the orbit in the inner portion of the roof of the antral cavity. When suppuration occurs in the anterior ethmoidal cells a similar condition is nearly always present in the frontal and antral sinuses.

The diagnosis, prognosis, and treatment of chronic ethmoidal suppuration cannot be dealt with now, for it would involve the description of complicated anatomical details and surgical technique. Suffice it to say that when ethmoidal suppuration is present the symptoms involve a purulent nasal discharge, a varying amount of nasal obstruction due to polypoid and hypertrophic degeneration of the ethmoidal mucous membrane. Local pain and discomfort in the nasal, lower frontal, and orbital regions are usually present, and not infrequently patients are subject to considerable mental depression and incapacity for mental exertion.

Ethmoidal suppuration is of importance because of the grave complications to which it may give rise. Should caries of a cell or cells take place with an extension of inflammation to the orbital contents sad results to the eye and eyesight may rapidly ensue. In other instances eyesight may be damaged or even lost by a slower inflammation of the optic nerve caused by the spread of inflammatory changes or infective conditions from the posterior ethmoidal cells, where they are in close relation with the optic nerve. More frequently posterior ethmoidal cell suppuration causes temporal contraction of the visual field, while general contraction is more common when the anterior cells are affected. This subject has been recently receiving a good deal of attention, and Professor Onodi of Budapest has added much to our knowledge in these matters. Still more serious are the meningeal inflammations which are not infrequently the outcome of chronic ethmoidal suppuration, and to those who constantly work in this department of surgery it must be a matter of surprise that these foci of suppuration so close to the brain and its meninges do not more often produce fatal results.

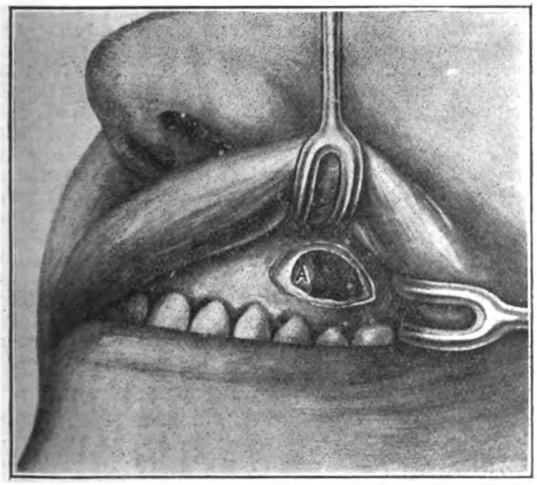
With regard to treatment I would only say that it is obviously surgical in nature, and that the great principle which should guide the operator is so to remove diseased structures that free intranasal drainage shall be permanently secured.



I make no apology for claiming that operative procedures in these regions should only be undertaken by those who are thoroughly conversant with the anatomy of the regions involved and who are skilled in the difficult technique of intranasal surgery. These regions are dark and must be well illumined so that the eye of the operator can see the end of his instrument. The parts are vascular, so that the surgeon must be prepared with means of checking the constant oozing of blood, and he must have patience to wait for a comparatively dry field in which to proceed with his manipulations. The bony structures are often soft and friable, and hence he must use no force in dealing with them. Vital structures are in close proximity to the limited area of operation, and hence the surgeon must have an almost instinctive knowledge of his whereabouts, and he should never be happy unless he feels that to the instrument which he holds in his hand there has been conveyed a tactile sensibility which is part and parcel of his own.

FRONTAL SINUS SUPPURATION.

[Some beautiful diagrams and lantern slides of the frontal sinuses were shown at the meeting illustrating their extreme variability in size and their relation to the orbits and meninges. (Figs. 5 and 6.) In some instances the sinus extended externally to the temporal region and backwards to the posterior limit of the orbit, and a patient was shown in whom at the time of operation the whole roof of the orbit and the posterior wall of the sinus had been destroyed by chronic suppuration, so that the orbital contents and the dura mater helped to form the walls of a large abscess cavity. The patient complained only of "seeing things double," and had never experienced any headache or other inconvenience.]



Frontal sinus suppuration may be acute or chronic. Acute inflammation is generally a complication of one of the acute specific fevers, and of these influenza accounts for more cases than all the other fevers together. I have seen cases complicating scarlet fever and they resembled in their acuteness

FIG. 1.

The anterior two-thirds of the inferior turbinal has been removed and an opening made in the inner antral wall.

FIG. 4.

A specimen dissected by lecturer illustrating the complicated cells forming lateral mass of the ethmoid. A, Hook drawing down the inner lip of the hiatus semilunaris to show normal "ostium" or opening of maxillary antrum into the middle meatus of the nose. B, Accessory antral opening. C, Opening of ethmoidal bulla into middle meatus. E, D, Posterior ethmoidal cells opening into superior meatus. (From Tilley's "Diseases of Nose and Throat." London: H. K. Lewis.)

FIG. 6.

Large left and small right frontal sinuses. Incomplete bony septa are seen in the left sinus which tend to divide that cavity into separate chambers or recesses. The left sinus extends considerably over to the right side and might easily be entered when operating on the right frontal sinus. (Figs. 5 and 6 kindly lent by Dr. Logan Turner, Edinburgh; *vide* "Accessory Sinuses of Nose," by same author. Wm. Green and Sons.)

and destructive nature the inflammations which are so commonly met with in the ear and the mastoid regions. One of the most extensive and affecting all the sinuses on each side occurred during an attack of typhoid fever. Chronic suppuration is usually due to a want of resolution of an acute inflammation and defective drainage of some kind is the chief factor which hinders such resolution.

ACUTE INFLAMMATION OF THE FRONTAL SINUS.

In addition to the symptoms of the general disease from which the patient is suffering we should expect to find severe pain above and around the eye on the side of the inflamed sinus. Often the pain induced by pressing upwards and inwards below the inner end of the eyebrow is excruciating. If intranasal drainage is free there may be little or no external signs suggesting that an inflamed sinus is the cause of headache, but if such drainage be obstructed redness and œdema of the upper eyelid and neighbouring soft parts may be very noticeable. The degree of pyrexia will vary with the amount of tension under which the pus is retained. An examination of the nasal cavity may reveal pus in the anterior region of the middle meatus, and it is sometimes possible to pass a fine probe or cannula into the sinus. When such good fortune occurs gentle irrigation with a warm, mild antiseptic will give great relief to the local symptoms.

Prognosis.—Most cases of acute frontal sinus suppuration recover spontaneously, probably because free drainage from the lower end of the sinus is naturally provided for. Septal deviations or hypertrophic irregularities in the neighbourhood of the anterior part of the middle meatus will, by obstructing free drainage, tend to check spontaneous resolution or inflammation.

Treatment.—Rest in bed, regular action of the bowels, hot fomentations externally, and the application of cocaine and adrenalin to the middle meatal regions are the best means of promoting subsidence of the inflammation. If the pain should increase and œdema of the eyelid appear, coupled with increasing pain on pressure over the anterior wall of the sinus, it will be wiser to adopt surgical measures. Possibly it will suffice to remove the anterior end of the middle turbinal and free the lower end of the fronto-nasal duct from any definite obstructions—this can only be done under general anæsthesia and needs care and special experience. It may then be possible to irrigate the sinus and quickly induce relief of symptoms. If the intranasal method affords no improvement, the sinus should be opened externally through the line of the eyebrow, the pus carefully washed out, and the fronto-nasal duct rendered patent by means of gentle probing or insertion of a fine rubber tube which can be removed in the course of a few days. Daily irrigation and light dressings will be required until the mucous membrane has returned to a normal condition, when the external wound may be allowed to close.

CHRONIC SUPPURATION OF THE FRONTAL SINUS.

Low resisting power of the patient, a virulent infection, and especially defective drainage are factors which tend to an acute inflammation becoming chronic.

Symptoms.—A purulent nasal discharge possibly associated with headache in the neighbourhood of the sinus are often the only symptoms complained of. Since the anterior and even the posterior ethmoidal cells are frequently in a similar condition of chronic inflammation and suppuration, polypi with consequent nasal obstruction and excessive discharge of mucus may be additional symptoms.

Diagnosis.—An inspection of the nasal cavity may reveal pus in the anterior region of the middle meatus. Frequently it will be possible to pass a fine cannula into the sinus, and if air be now injected the pus may be seen issuing by the side of the cannula where it disappears from view in the higher regions of the nose. A frontal skiagram of the inflamed sinus will show it to be more opaque than on the healthy side, and this means of diagnosis has a further advantage in that, if a profile view be taken, we can gauge the depth of the sinus from before backwards and thus estimate the probable amount of deformity if an external operation be decided on—a matter of some importance if the patient is a female.

Prognosis.—Once chronic suppuration is established in the frontal sinus, cure is not easily brought about without intra- or extra-nasal surgical treatment. I have had a few cases in which frequent irrigation and injection of strong astringents and antiseptics have been followed by a cure, but they are the exception rather than the rule, and this happy result is probably due to very free drainage of a sinus possessing a regular contour in which there are no pockets or recesses where pyogenic organisms can lurk and flourish. When drainage is impeded there is a tendency for the sinus walls to expand or to be slowly destroyed, so that neighbouring important structures such as the orbit or meninges are endangered, or a subperiosteal abscess may form, burst, and an external fistula result.

Treatment.—When intranasal drainage is free it is always worth while to try the effect of daily irrigation and the injection of strong solutions of silver nitrate, from 60 to 80 grains to the ounce, or of tincture of iodine, 1 drachm to a pint. To promote such free drainage it may be wise to remove the middle turbinal and some anterior ethmoidal cells. By such means suppuration may sometimes be so much diminished and other symptoms relieved that the patient prefers to let matters remain thus, even though a complete cure has not been attained.

On the other hand, there are many instances where free drainage is difficult to secure by intranasal methods, or there may be evidences that the inflammation is extending beyond the sinus, or the patient may be suffering from profuse discharge, constant headaches, or he may be going to parts of the world where skilled help will not be obtainable; and under these and other circumstances an absolute cure of the suppuration may be desirable. This can only be secured by an external operation the aim of which is to completely obliterate the sinus by the formation and ultimate organisation of granulation tissue. Many operations have been advocated from time to time, but probably the best is that advanced by Killian (Berlin), in which the anterior wall and floor of the sinus are completely removed, as well as any neighbouring ethmoidal cells which are simultaneously diseased. By leaving a "bridge" of bone in the lower anterior wall of the sinus Killian's operation has done much to minimise the deformity which was the defect of many other operations formerly practised.

Slight deformity is nearly always present unless the sinus be small and shallow from before backwards, and, as I have said, the amount of probable depression can be fairly estimated by a skiagram of the sinus seen in profile.

Operations on the frontal sinus, especially for the cure of chronic suppuration, must be carried out with rigid regard for asepsis and the establishment of free drainage during the first ten days or fortnight following the operation. This warning is very necessary, because for reasons not altogether obvious the diploë of the frontal bone are peculiarly liable to septic infection, and once osteomyelitis has started only the most heroic and extensive removal of the frontal bone offers any chance of saving the patient's life.

Bacteriology of frontal sinus suppuration.—According to Lewis and Turner, "pus from the frontal sinus presents, as a rule, fewer varieties of bacteria than does pus from the antrum. It is more easy to assign predominance to one organism, and it appears that cocci of one kind or another are generally responsible."

INFLAMMATION OF THE SPHENOIDAL SINUS.

[The relations of this deep-seated sinus to the optic chiasma and nerves, to the sella turcica and frontal lobes of the brain, to the carotid artery and cavernous sinus, the third, fourth, and sixth cranial nerves, and its intimate connexion with the posterior ethmoidal cells were dwelt upon. (Fig. 7.) A graceful tribute was paid to Professor Onodi of Budapest, who had done so much in elucidating the anatomy of this sinus, and many of whose beautiful diagrams were shown during the course of the evening.]

Acute and chronic inflammatory conditions are caused by conditions almost identical with those already described in connexion with the other sinuses. We know little concerning acute primary inflammation of the sphenoidal sinuses. Chronic suppuration is nearly always associated with the same condition in the other sinuses, and more particularly with the ethmoidal cells.

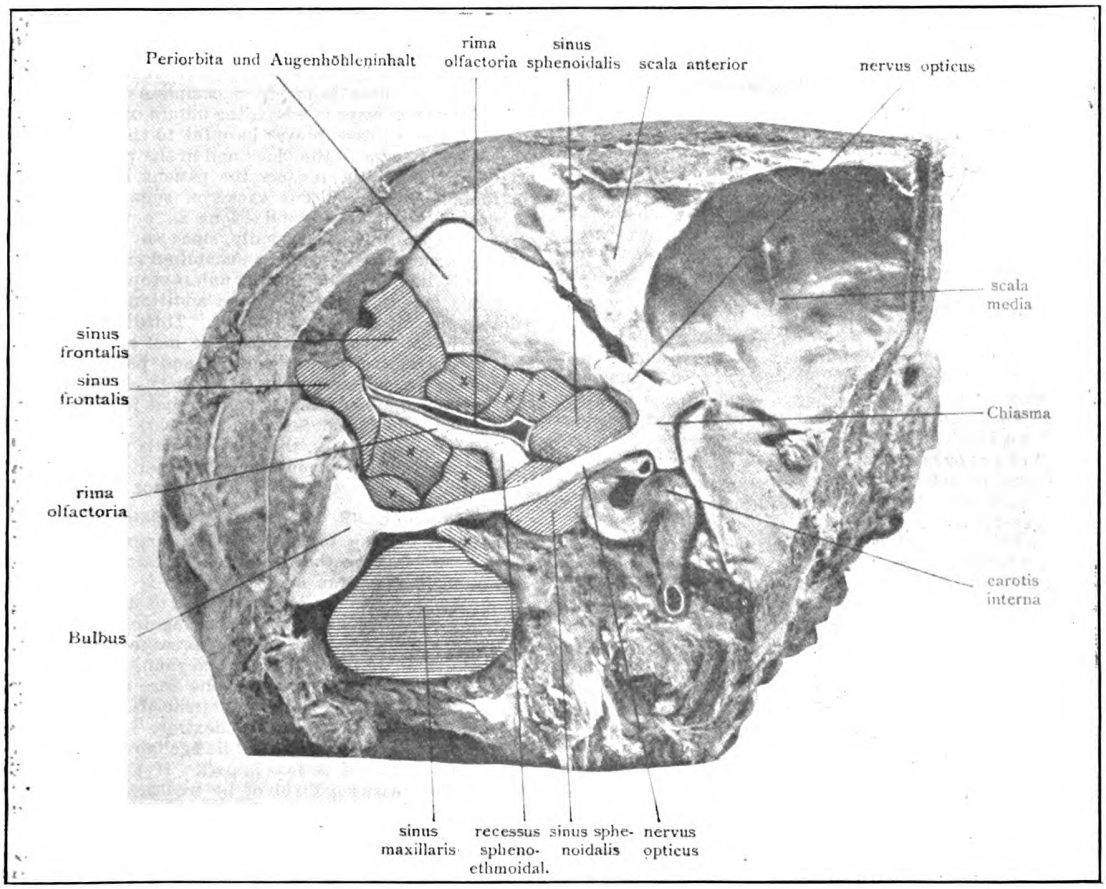
Symptoms.—Subjective symptoms may be entirely absent, or the only complaint may be of "post-nasal catarrh." In other cases there may be some vertical or occipital headache. Still less frequently "earache" may be the chief complaint, as I pointed out some six years ago.

Inflammatory affections of the optic nerve, general or temporal contraction of the visual field, and other ocular disturbances have been recorded in many instances of chronic sphenoidal sinus suppuration, and this is only what

one might expect when the close relationship of the structures is borne in mind. Two observers have stated that half the cases of unilateral optic neuritis are of nasal origin, but this is probably an exaggeration.

Suppurative basal meningitis and cavernous sinus thrombosis are complications which are always possible when chronic suppuration exists in the sphenoidal sinus, and there can be no doubt that the source of many cases of unexplained and fatal meningitis has been within the sphenoidal sinus which has not been examined during life or thought of during the necropsy. StClair Thomson has collected 40 cases of intracranial complication following sphenoidal sinus suppuration, and has added two of his own.

Diagnosis.—This will involve a careful examination of the higher and posterior regions of the nasal cavity, to gain access to which it may be necessary to remove the middle turbinal bone. When suppuration is present a pulsating drop of pus may be frequently seen in the ostium of the sinus. Its presence within the cavity can be accurately determined by means of probe or cannula.



Prognosis.—This is usually very good if efficient drainage is provided by surgical intervention before dangerous symptoms have manifested themselves.

Treatment.—The operation usually involves removal of the middle turbinal and posterior ethmoidal cells in order to gain access to the anterior wall of the sinus. Hæmorrhage having been checked by the free use of gauze tampons moistened with adrenalin solution or peroxide of hydrogen, the anterior wall of the sinus can be removed by the use of suitable hooks or forceps. No curetting of the sinus walls is necessary nor is it advisable, for if free drainage be secured the inflamed mucous membrane will soon recover its normal condition.

I think my colleagues in this department of surgery will agree with me that chronic suppuration in the sphenoidal sinus is a favourable condition for surgical treatment, and a well-executed operation is usually fraught with the happiest results, for the symptoms are cured without any sign-manual of the surgeon's visit.

May I once more emphasise that the regions in the neighbourhood of the sphenoidal sinus demand the most careful manipulations. The reckless use of probes or curettes, blind or forceful probing, may have disastrous results; and hence the surgery of these regions must be entrusted to those who have devoted a large amount of time to the practical aspects of the subject.

FIG. 7.

To illustrate the intimate relations of the frontal ethmoid and sphenoid sinuses to the eyeballs, optic nerves, and chiasma, and carotid artery. Kindly presented to the lecturer by Professor Onodi (Budapest). The soft tissues of the sinuses and surrounding parts are hardened in formalin and the bony parts then carefully removed. The Latin descriptions explain themselves. "Augenhöhleninhalt" may be translated by "contents of orbit."

CONCLUSIONS.

Finally, what practical conclusions are we to draw from the facts which I have attempted to bring forward? Someone may ask, What is the frequency of suppuration in the nasal accessory sinuses? Very careful observations have been made in large clinics as well as in the post-mortem rooms of general hospitals, both at home and abroad, and they agree in showing that about 6·8 per cent. probably represents the average of sinus suppuration in the general mass of the population.[2]

Another and an important question is, To what degree does the presence of chronic suppuration in one or more sinuses (*a*) imperil the patient's health; (*b*) constitute a danger to life?

[2] Vide Comrie and Fraser, Edinburgh Medical Journal, November 1910.

For nearly 20 years I have been deeply interested in the matters under discussion, and am quite sure that no hard-and-fast or categorical answer can be given to these questions. In no department of surgery must a case be treated more upon its merits than in this. In the first place, much will depend on the sinus or sinuses involved. Compared with the other air cells, the antrum is far removed from vital or important structures, such as are in close relation with the sphenoidal, ethmoidal, and frontal sinuses.

Then, again, how frequent it is to be consulted by a patient who says that for years he has had "chronic nasal catarrh," which the history and examination clearly prove to be a foul empyema of the antrum, and yet the patient appears to be in robust health and possibly boasts that he has never had a day's illness in his life. A bacteriological examination of the pus from his antrum may show that it contains a variety of organisms possessed of great possibilities for evil, but in the laboratory of his body protective substances have been formed which seem to make him proof against the products of the local suppuration. In another and apparently identical case the general health may be seriously undermined by gastric disturbances, mental depression, or by one or more of a host of symptoms which render life intolerable, and that the local suppuration is the cause is proved by the fact that when the disease is removed the patient has rapidly regained his normal condition of health. Between such extremes there are many intermediate types and our line of treatment must be proportioned to meet the needs of the case. There will, of course, be less hesitancy in advising radical measures in the case of the antrum because there is little risk in the surgical measures which I have already outlined, recovery is rapid, and great relief or cure is generally attained.

The question is not so easily disposed of when we have to deal with the frontal, ethmoidal, or sphenoidal sinuses—or, what is very frequent, a combination of these sinuses in a state of suppuration. I would at once say that the mere fact of chronic suppuration being present in one of these sinuses in a patient whose general health is good, in whom there are no local symptoms of importance beyond a slight discharge of pus or muco-pus from the nose, does not warrant the surgeon in advising radical operations until simpler measures have been tried and there are cogent reasons for passing to severer ones.

Once or twice a year I see patients who consulted me 15 or 18 years ago for a nasal discharge which was more of a "slight inconvenience than a disease"—simple measures were adopted in some cases because (and possibly contrary to my advice) the patients would not submit to radical operation—and to-day these people are no worse and some of them are better than when I first saw them, although it is as obvious now as it was then that the higher sinuses are in a state of chronic suppuration. The drainage has been kept free, and probably they are protected by antibodies or opsonins manufactured in their own tissues.

But I have less happy memories than these, for in those pioneer days of nasal surgery the mere fact of pus being present in a sinus was considered a sufficient reason for immediate and often radical operations. The possibilities of intracranial infection, ocular lesions, ulcerative gastritis, infection of the lower air-passages perhaps culminating in septic pneumonia, appeared to many of us by no means impossible results of a neglected sinus suppuration. And in that faith, and acting in the light then vouchsafed to us, I fear that our surgical records were not free from disaster and that a life was sometimes lost in our endeavour to cure what might have proved merely an inconvenience. In yet other instances an unsightly depression over one or both eyebrows serves to remind us of what was possibly a misdirected enthusiasm.

To-day the pendulum has swung back somewhat and our first efforts are directed to the relief of symptoms by intranasal measures which in skilled hands involve little risk; and I think we are agreed that sometimes a cure, and certainly very often great improvement, may thus be gained—the latter to such a degree that both surgeon and patient are content to let matters rest awhile and see how far Nature will add still further to the good result. If, on the other hand, troublesome symptoms persist, or more serious ones threaten, then more radical measures must be undertaken. These will involve a knowledge of anatomy and technique which cannot be acquired from books, but only from patient investigation of the carefully prepared specimens to be found in our museums or post-mortem rooms, and by watching operations and after-treatment carried out by those whose disappointments and failures in earlier days have disclosed many of the little secrets which to-day enable them to intervene not only with courage but with a gratifying proportion of success.

Two Lectures
ON
THE TREATMENT OF DIABETES MELLITUS.

Delivered at St. George's Hospital

BY EDMUND I. SPRIGGS, M.D. LOND., F.R.C.P. LOND.,
SENIOR ASSISTANT PHYSICIAN TO THE HOSPITAL.

LECTURE I.

GENTLEMEN,—Although our knowledge of the pathology of diabetes mellitus is far from complete, we are able to recognise three ways in which the failure of the oxidation of sugar in this disease proves harmful to the body. Firstly, the excess of sugar in the blood and in the urine causes polyuria and thirst, and renders the patient liable to various septic inflammations. The excess of sugar is probably also responsible for such complications as neuralgia, sciatica, cataract and retinitis. Secondly, since so much food value is passed out in the urine as unoxidised sugar and lost, the patient is liable to be underfed unless steps are taken to see that this loss is made up by the addition to the diet of a suitable amount of oxidisable food. Thirdly, as the energy for the needs of the body has to be met almost exclusively from the burning of protein and fat, and particularly of fat, the tissues responsible for the metabolism of fat are liable to fail in the complete combustion of that foodstuff, with the result that unoxidised fatty acid appears in the blood and tissues. In such cases, this fatty acid is more to be feared than sugar, for unless you are able either to neutralise it or to lessen its formation it may lead to poisoning.

SOME POINTS IN PROGNOSIS.

I am not dealing to-day with the diagnosis of diabetes mellitus, and assume that we have ascertained that dextrose is present in the urine and that there is no evidence of a removeable lesion in the neighbourhood of the pancreas. In passing I must, however, warn you against attaching too little or too much importance to the presence of dextrose and of diacetic acid in the urine. In the young, glycosuria, with or without diaceturia, always calls for serious attention unless perhaps—an uncommon circumstance—it can be shown that a large quantity of dextrose has been recently taken by the mouth. When middle age is reached glycosuria may or may not be of serious import. If the amount is not large, if it is easily got rid of by treatment, if there is no diacetic acid in the urine, or if the glycosuria accompanies some other morbid condition and improves with that, it may pass off entirely or remain in small degree with no evil consequences. As an example of glycosuria accompanying another morbid state and recovering with it, I may quote the case of a patient suffering from failure of compensation of the heart, with hydrothorax, ascites, and œdema; the urine contained albumin and sugar. I advised his doctor to take no notice whatever of the sugar. Under the influence of rest and large doses of digitalis the heart became compensated, and in six months the urine contained neither sugar nor albumin.

With larger amounts of sugar, especially when accompanied by diacetic acid, more active treatment is required. Even if diacetic acid is present, however, be very careful how you form a conclusion about the severity of the case. The fatty acids in the urine in diabetes have only been regularly observed by physicians for a few years yet, and although their constant presence in severe cases points out their great importance to the prognosis, yet I can think of patients in the fourth and fifth decades of life who, to my knowledge, had diaceturia several years ago, and are in good health now. Here, again, the possibility of the removal of any cause of strain, such as overwork, is of great importance. For example, a patient whose business involved

habitual overwork had glycosuria 15 years ago, and diaceturia as well when I saw him first six years ago. He was able to alter his manner of life and both are now absent, whilst his general health is good and he takes a mixed diet, though he is naturally careful to eat only a moderate amount of starchy foods.

Bearing in mind, then, the importance of not giving a prognosis graver than the event is likely to justify, you will, nevertheless, always pay close attention to the presence of the diacetic reaction in the urine, and I advise you to divide cases of diabetes mellitus for the purpose of treatment into two classes—namely, cases in which the reaction is absent and cases in which it is present.

ACIDOSIS.

You know that besides diacetic acid β oxybutyric acid and acetone occur in the urine. If these substances are present in quantity diacetic acid is also present, so that the ferric chloride reaction may be taken as a reliable clinical guide. But a mild degree of acidosis may be present without the occurrence of this reaction. If a drachm of bicarbonate of soda is given to a healthy person the urine becomes alkaline in a few hours and may remain so for 24 hours. If a certain degree of acidosis is present, however, either in diabetes or in other diseases, more soda is required to render the urine alkaline; indeed, in severe diabetes a very large quantity, ounces a day, may not have this effect for two or three weeks. Hence in all cases of diabetes give first of all a drachm of bicarbonate of soda three times a day, usually in milk, and have the urine tested with litmus to see when it becomes alkaline. If that happens soon the degree of acidosis is slight. If the urine does not become neutral or alkaline the soda is increased so far as practicable until it does. A measure is thus obtained of the degree of acidosis. I must warn you that the intensity of the diacetic reaction is increased by giving bicarbonate of soda, presumably owing to washing out of acid products or to the conversion of more of them to the stage of diacetic acid; you must not, therefore, look on the deepening of the reaction as meaning that the condition is worse when alkali has been given; it may mean just the reverse.

ESTIMATION OF SUGAR AND RESTRICTION OF DIET.

The next step is to find out how much sugar is passed out in the 24 hours on the ordinary diet of the patient. The total figure must be obtained, for the percentage only may be very misleading. As the quantity of sugar varies from day to day it is better to estimate it for three days running and take the average. Dr. Pavy's method is by far the most accurate of the quick methods of estimating sugar in the urine. Remember that if you are not doing estimations regularly you may obtain a figure lower than the real one without recognising the error on repeating the test. You must guard against this by not dropping in the diluted urine too quickly. Count the drops, and if you can decolourise the copper solution with a fewer number of drops the second time than were used the first, the estimation should be repeated until you obtain three concordant figures of which you take the mean. The tests in which you use the larger number of drops are usually wrong and lead to the amount of sugar in the urine being underestimated. The gravimetric method of estimating sugar is still more reliable, and my practice is to have this done by an analytical chemist whenever possible, using Dr. Pavy's method if an immediate estimation is required.

Having found out how much sugar is being passed out on the average from an estimation, if possible, on three separate days, you will proceed to restrict the carbohydrates in the food. The restriction of carbohydrate has two good effects. Firstly, it lessens the amount of sugar in the blood and abolishes, except in the most severe cases, the symptoms due to an excess of sugar in the blood and in the urine. Secondly, doubtless again through lessening the sugar in the body fluids, the power of the tissues to burn carbohydrate becomes restored. The second effect is of fundamental importance. You may easily relieve your patient's symptoms in most cases by restricting his diet somewhat, but you must go further than that and find out what his assimilative power for carbohydrate is, and how much it can be improved. This investigation involves a certain amount of arithmetic and requires the active coöperation of the patient. Your procedure will differ somewhat according as diaceturia is present or absent.

If the diacetic acid reaction is absent, and if the urine rapidly becomes alkaline under the influence of bicarbonate of soda, the restriction may be made without fear of causing acid poisoning. Even in such cases, however, I do not advise you to put the patient upon a strict diet at once. For by putting a patient upon a strict diet you can induce a diaceturia which has not previously been present, and this is undesirable, even if the sugar entirely disappears. The diabetic, to begin with, cannot oxidise sugar properly; the appearance of the diacetic reaction means that another foodstuff, fat, is also no longer freely oxidised. Whilst, therefore, acknowledging that a large number of glycosuric patients can be put on a strict diabetic diet with impunity, my advice to you is not to do it. You can produce the same good result by going a little more carefully without the same risk of disadvantage.

There is another reason why it is not advisable to order a strict diet at once, and that is that many patients will find the sudden change so irksome that they will not carry it out properly. Your instructions are far more likely to be obeyed throughout if they are reasonably lenient at first. Some patients are but little inconvenienced by the diet prescribed, others need great self-control to adhere to it; you must recognise this and show your sympathy by not asking too much. For the same reason, always allow as much bread as you can, for that is the food which is missed the most.

AMOUNT OF CARBOHYDRATE IN VARIOUS FOODS.

The following tables may help you in drawing up a diet. They are compiled from the modern analyses of Atwater and Bryant, and you will see that I have arranged the foods in three lists. The first list includes foods which are free from carbohydrate or contain less than 1 per cent. In the second list the foods contain a small proportion of carbohydrate, much of it in some of them being in the form of cellulose, which is not absorbed. The third list contains articles of diet which are richer in starch or sugar arranged according to the amount which they contain.

All patients are allowed to eat freely from the foods in List 1, most patients may also take the foods in List 2, whilst those in List 3 are only allowed when specially prescribed in measured quantities.

LIST 1.—*Foods Free from Carbohydrate or Containing Less than 1 per cent.*

Beef.	Turtle.	Gelatine.
Mutton.	Lobster.	Starch-free "breads."
Lamb.	Eggs.	,, biscuits and cakes.
Pork.	Butter.	,, "flour."
Poultry.	Cheshire cheese.	Sugar-free jellies.
Game.	American ,,	,, marmalade.
Sweetbread.	Dutch ,,	,, jams.
Tongue.	Gorgonzola ,,	
Fish.	Lard.	

LIST 2.—*Foods Containing a Low Proportion of Carbohydrate.*
The figures indicate the percentage of carbohydrate.

Liver	1	Lettuce	3	Mixed pickles	4
Sausage (pork)	1	Spinach	3	Cauliflower	5
Crabs	1	Oysters	4	Cabbage	6
Crayfish	1	Mussels	4	Leeks	6
Scallops	3	Stilton cheese	3	Radishes	6
Asparagus	3	Cheddar ,,	4	Mushrooms	7
Celery	3	Rhubarb	4	Water melons	7
Cucumbers	3	Tomatoes	4	Brazil nuts	

LIST 3.—*Foods Rich in Carbohydrate.*

Milk	5	Artichokes	17	Bread (toasted)	61
,, skimmed	5	Peas (green)	17	Peas (dried)	62
Whey	5	Cherries	17	Gingerbread	63
Oatmeal (thin gruel)	6	Almonds	17	Macaroons	65
Strawberries	7	Potatoes	18	Sponge cake	66
Turnips	8	,, with cream	18	Oatmeal	67
Carrots	9	Dried pears	18	Chestnuts (dried)	74
Beet (fresh)	10	Figs (fresh)	19	Sago	78
Onions (fresh)	10	Grapes	19	Taploca	88
Cranberries	10	Plums	20	Arrowroot	97
Pineapple	10	Potatoes (boiled)	21	Dried fruits—	
Oatmeal (boiled)	11	Bananas	22	Apples	62 to 78
Blackberries	11	Rice (boiled)	24	Apricots	
Dried peaches	11	Taploca pudding	28	Currants	
Oranges	12	Cocoanuts	28	Dates	
Parsnips	13	Chocolate	30	Figs	
Apricots	13	Mince pie	38	Prunes	
Currants	13	Chestnuts (fresh)	42	Raisins	
Walnuts	13	Apple pie	43	Meal	70 to 80
Filberts	13	Bread (brown)	47	Flours	
Apples	14	Potatoes (fried chips)	47	Rice	
Pears	14	Bread (white)	53	Macaroni	
Macaroni (cooked)	16	,, (rolls)	56	Vermicelli	
Calves-foot jelly	17	Lentils (dried)	60		

ARRANGEMENT OF DIET.

In the case we are considering—namely, that of the patient who is passing out sugar but no diacetic acid—you may begin by allowing about as much carbohydrate as he is passing out in the urine. If the urine contains, for instance, 150 grammes of sugar you can easily devise from the list a diet containing that amount of carbohydrate. In making such a calculation you will require but few figures, even if the lists are not at hand. It is useful to remember the following data, which are in round figures :—

Bread contains 60 per cent. of starch.
Potatoes contain 20 per cent. of starch.
Milk contains 5 per cent. of milk sugar.
Thin gruel contains 6 per cent. of starch.
One ounce is (roughly) 30 grammes.
One gramme is 15 grains.

A diet containing about 150 grammes of carbohydrate may be constructed as follows :—

	Grammes of carbohydrates.
5 ounces (150 grammes) of milk ... ... equal	8
5 ,, ,, ,, of gruel ... ... ,,	9
6 ,, (180 grammes) of bread ... ... ,,	108
2 ,, (60 grammes) of boiled potatoes ... ... ,,	12
Ordinary helpings of the foods in List 2 (estimate) ...	20
Total	157

The diet will then consist of the foods in Lists 1 and 2, with the quantities prescribed above of the foods in List 3. Sugar and jam and dishes or foods made with flour are, of course, not allowed. Saccharin may be used for sweetening tea or coffee, though it is better to form the habit of taking them unsweetened, as much saccharin may cause indigestion.

Such a diet may be arranged as follows :—

Breakfast.—A small basin of thin gruel with 5 ounces of milk; 3 ounces of bread; butter, bacon, eggs; a tomato; coffee with cream.
Lunch.—Meat or fish, pickles, 1 ounce of potatoes, butter, greens; green salad with salad oil; 1 ounce of bread with cheese and celery.
Tea.—2 ounces of bread with abundance of butter; a boiled egg; tea with cream.
Dinner.—Soup (containing no flour), fish, meats, 1 ounce of potatoes, spinach; custard made with cream and saccharin; cheese with some starchless bread, celery; a few Brazil nuts.

The diet will be varied from day to day, the quantity of carbohydrate being kept constant. After three days the urine will be analysed. If the quantity of sugar is much less, continue the diet for another week and make another analysis, and so on for as long as the sugar in the urine is falling.

If there is little or no reduction of the sugar, or if the quantity has ceased to fall or is rising again, the carbohydrate should be reduced by 50 grammes. This may be done by omitting the 2 ounces of potatoes and 2 ounces of bread, leaving the diet otherwise the same. The diet will then be :—

	Grammes of carbohydrate.
5 ounces of milk ... ... equal	8
5 ,, of gruel ... ... ,,	9
4 ,, of bread ... ... ,,	72
Ordinary helpings of foods in List 2 (estimate)	20
Total	109

With this diet the patient would take freely of the foods in List 1 and moderate helpings from those in List 2.

If after five days on the above diet sugar is still present in quantity, you will omit the potatoes and milk, reduce the bread to 3 ounces, and allow from List 2 only well-boiled greens and a tomato. The carbohydrate in the diet will then be :—

	Grammes of carbohydrate.
5 ounces of gruel ... ... equal	9
3 ,, of bread ... ... ,,	54
Estimate of foods from List 2	10
Total	73

The rest of the food will be made up from List 1.

With such a diet in many cases sugar will no longer appear in the urine. If, however, there is still a quantity of 20 grammes or more passed out, the carbohydrate will be still more reduced by allowing only 2 ounces of bread in the day with greens and one tomato from List 2. These will contain about 46 grammes of carbohydrate. With such a diet as this care should be taken to alkalise the urine by giving bicarbonate of soda while the restriction is in force.

Before this stage it will be necessary to provide some substitute for bread, such as the starchless breads made by Callard and the Protene Company and other manufacturers, of which the patient will be instructed to eat freely with abundance of butter. Puddings and other dishes may be made by the use of the starch-free flour.

In the milder cases we are considering the urine will now be free from sugar. The allowance of carbohydrate will then be increased, going back through the same stages. By this means it will be possible to ascertain easily how much carbohydrate the patient can take in the diet without any of it appearing in the urine. The chief aim is to keep this quantity—namely, the quantity of carbohydrate which can be assimilated—as high as possible.

FURTHER OBSERVATIONS.

Do not, however, form the idea that there is a fixed quantity of carbohydrate which the patient can assimilate. That is not the case. The quantity varies from time to time, and under proper treatment may become larger and larger. Some kinds of carbohydrate are also assimilated better than others. You will give in the course of treatment various kinds to your patient in order to find out whether he can, for instance, assimilate the starch of oatmeal better than that of bread, or whether levulose is better borne than dextrose. You will see that to obtain a correct picture of the patient whom you are treating it is necessary to take a good deal of trouble and to give the patient a good deal of trouble, for the collection of the 24 hours' total urine is, in ordinary life, an inconvenient business. It is sometimes impossible to have it collected on consecutive days. In that case samples are taken at the week-end, when the patient has leisure. The ideal plan would be for every patient to be carefully observed for at least a month with different diets and different kinds of carbohydrate. After such an investigation we should be in a much better position to advise than after one or two examinations of the urine. But this is seldom possible in mild cases, and you will often have to extend your observations over a longer period with considerable intervals between each. When you have found out how much carbohydrate can be assimilated you will order a diet containing rather less than this quantity.

The success of dietetic treatment depends very largely upon the skill in cooking which is at the disposal of the patient, and particularly upon the varieties of appetising dishes which can be made from the foods in List 1 with the help of the starchless flour and the various sugar-free jams and cakes which are provided by the manufacturers. If the patient is on a fixed allowance of carbohydrate it is a good plan to supply him with a list of the various ways with which he can supply that amount. With the aid of the analyses which I have given above this is quite easy to do.

In my next lecture I shall speak of the treatment of cases in which diacetic acid is present in the urine.

ON POST-NASAL CATARRH IN CHILDREN AND SOME OF ITS CONSEQUENCES.

BY EUSTACE SMITH, M.D. LOND., F.R.C.P. LOND.,
SENIOR PHYSICIAN TO THE EAST LONDON HOSPITAL FOR CHILDREN.

OF late years I have been in the habit of examining the fauces of all children who have been brought to me suffering from loss of appetite, gastric derangements, spasmodic conditions of the air-tubes, and obstinate coughs. In a very large number of these cases I have found the patient to be suffering from a more or less intense post-nasal catarrh. This catarrh is often confined strictly to the naso-pharynx, and does not pass into the nasal passages. While thus limited it may give rise to none of the usual signs of "a cold" in the nose, such as snuffling, sneezing, and external discharge, or even to a throaty quality in the voice. It may therefore remain latent and escape notice for weeks, or even months, together unless the throat be inspected in a good light. I have often been surprised at the intensity of the catarrh which an examination has shown can be fixed in the naso-pharynx without giving rise to a single local symptom to make its presence known. But whether or not it be associated with the ordinary symptoms of coryza, post-nasal

catarrh may be the source of widespread disturbances. These at first sight may not be of such a nature as to suggest a relationship with the state of the pharynx; but that the connexion, however obscure, is a very real one is seen in the successful results of treatment founded upon that assumption. When the catarrh goes on for months together it is, no doubt, being continually renewed; and the symptoms may be noticed to wax and wane according to the varying severity of the pharyngeal derangement. This rarely ceases completely, but if in a fairly long spell of genial dry weather the catarrh for a time comes to an end, it often returns at once when the weather again becomes changeable and damp. Some of these children suffer from a certain amount of adenoid overgrowth in the naso-pharynx, but in many the adenoids have been already removed. In the latter it is common for a return of the vegetations to be suspected on account of signs of obstruction to the posterior nasal openings arising from the thickened and swollen mucous membrane. But adenoids rarely return if their extirpation has been complete, and most of the cases of suspected renewal are of this kind.

The appearance of the fauces varies according to the intensity and duration of the catarrh. In cases of long standing the mucous membrane at the back of the pharynx is thickened and red like red velvet, and is bathed in secretion. In less severe cases the posterior wall is thickened and reddened and often uneven from shallow projections of the surface. These are redder than the mucous membrane around them. The surface is moist and is often covered with thick yellowish mucus, which may be seen flowing down from above. In bad cases enormous quantities of this mucus may be secreted, and as it is all swallowed and passed down into the stomach the gastric irritation set up by this continual inflow of acrid and often highly septic matter is not difficult to understand. A bacteriological examination of the mucous discharge taken from the pharynx was made for me in several cases by my house physician, Dr. G. Walker. The secretion contained, as might be expected, a great excess of the micrococcus catarrhalis, but mixed with these in the various specimens were Friedländer's bacillus, the bacillus septus, and more or less numerous staphylococci. In one case Dr. Walker found three Klebs-Loeffler bacilli of involution forms and a few pneumococci. Sometimes the uvula and soft palate are thick-looking and congested, but the tonsils are not necessarily enlarged. This state of derangement, I may again repeat, may remain unsuspected for months together if it be not associated with signs of coryza, for while it remains limited strictly to the fauces there is no pain in swallowing or other symptom pointing to the naso-pharynx. It is only by actual inspection of the throat that the existence of any morbid condition can be ascertained. Even after the inflammation proper is at an end its ill consequences remain as long as the free secretion of mucus persists. Therefore, if the posterior wall of the pharynx be found to look pale, thick, flabby, and moist, active treatment with astringent applications should be adopted without unnecessary delay.

One of the commonest consequences of this persistent post-nasal catarrh is complete loss of appetite. This is shown, not by a mere indifference to food, but by an active dislike to it, which is very striking and difficult to overcome. The children are generally pale, but show little sign of illness, and are cheerful and active in their games. As the mother remarks, "there does not seem to be much the matter with the child, but he will not eat." At every meal the same difficulty occurs, and much strategy may have to be employed to get him to swallow even a small quantity of food. It has often surprised me to notice that the subjects of so much perplexity and concern are not necessarily thin or obviously ill-nourished. This is probably owing to the fact that a child who will not eat can often be made to drink, and, indeed, may be ready enough to do so without any persuasion. He consequently takes large quantities of milk in the course of the day, and the deficiency in his regular meals may be thus more or less completely repaired. This absolute loss of appetite is a very common symptom in children between the ages of 4 or 5 and 9 or 10 years, although in other respects they may seem to be healthy enough. If the fauces of these children be examined there are very few in whom the pharynx will not be found to be in a state of active catarrh, or to have been left flabby, relaxed, and freely secreting after the acute stage has passed away, although no symptom pointing to the throat may have been noticed; and appropriate treatment of the derangement will rarely fail to restore the child's inclination for food and relieve the anxiety of his friends.

In some of these cases, in addition to the loss of appetite, which is a persistent fault, there may be signs from time to time of active disturbance of the stomach. Not a few examples of the so-called "cyclical vomiting" are of this nature. The child every month or six weeks is taken more or less suddenly with an attack of vomiting in which for 24 hours or more he returns at once everything, even water, which he takes into his stomach. His temperature is high, rising often to 104° or 105° F. at night. In the beginning the vomited matters are sour; later, when he is drinking nothing but water, the fluid is returned as it was taken; but, as a rule, vomiting quickly ceases when food is withheld. When these attacks are associated, as they so often are, with post-nasal catarrh I attribute them to an acute exacerbation of the catarrh in which a fresh secretion of peculiarly acrid mucus, teeming with more or less noxious organisms, is poured out and swallowed. This tainted secretion excites a septic fermentation in the alimentary canal, and the products are immediately absorbed into the circulation. It is possible that there may be a neurotic element in the illness, but that it is not a pure neurosis, as is usually assumed, is proved, I submit, by the fact that the temperature is excessively high, that the vomited matters are sour and offensive and show every sign of digestive derangement, and that the course of the complaint may be shortened, and a further recurrence prevented, by careful diet and early attention to the condition of the throat. At the same time it is, of course, advisable to take steps to put an end to periodical chills, so that the effect of the remedies may not be weakened or annulled by future repetitions of the original disturbance.

But these attacks of vomiting and general depression may not be the only evidence of intestinal intoxication. Such septic infections are capable of giving rise to local as well as general distress, and may be the cause of serious inflammatory mischief in distant tissues and organs. It is not now disputed that to toxæmic conditions many inflammatory diseases which arise without obvious cause may be directly attributed. Meningitis, appendicitis, otitis, iritis, and it has been lately suggested poliomyelitis, may all owe their origin to toxins generated in the bowel by such an incursion of virulent organisms; and cases have come under my own observation in which repeated attacks of retinitis and other obscure inflammatory or semi-inflammatory states of the eye, with threatened failure of sight, have been associated with, and I believe were the direct consequence of, persistent or very frequently recurring naso-pharyngeal catarrh.

To return to the everyday consequences of this functional disturbance of the naso-pharynx, it may be stated that loss of appetite and indigestion arising from this cause are not confined to children. In young adults of both sexes a peculiar susceptibility of the fauces may be left as a consequence of an attack of diphtheria or scarlet fever. These patients are liable to periods of indisposition in which they complain of a loaded tongue, unpleasant breath, and want of all relish for their food. There is seldom mention of sore-throat, but the voice has a nasal quality, and examination shows that there is much post-nasal catarrh with copious secretion, and that the tonsils, although not acutely enlarged, look red and may perhaps show retained yellowish matter in the follicular recesses.

Between post-nasal catarrh and spasm of the air-passages (stridulous laryngitis and laryngismus stridulus) in young children there is a close relationship to which I have drawn attention on many previous occasions. The more I see of these complaints the more convinced I become that post-nasal irritation is the common exciting cause of these attacks when the reflex spasm occurs in children whose glottis is of normal construction and development. But it is not only local spasm which may be excited by post-nasal irritation in early life; general convulsions may be induced by it. The apparently causeless convulsive attacks which sometimes occur in young children of rickety tendencies are often the consequence of this condition of the naso-pharynx—at least, a severe post-nasal catarrh may be the only deviation from a normal state of health which the closest examination can discover.

In young children up to the age of two years, and in children of neurotic tendencies who have passed that age,

the presence of acute and subacute post-nasal catarrh is often sufficient to induce a rise of temperature. This may be curiously erratic and unsettled. In a brief space of time the mercury may shoot up from the level of health to 102° or 103° F., and after an hour or two fall again to its normal point. This rise is especially likely to happen towards the end of digestion, or a couple of hours or so after food, and I am disposed to attribute it to the absorption from the stomach of mildly irritating products of decomposition. The pyrexia thus induced may be a cause of some perplexity for no symptoms may be present to point to the throat, and unless the fauces be examined the origin of the febrile movement must remain a mystery.

A very common consequence of post-nasal catarrh is acute enlargement of the cervical glands. The connexion between the state of the glands and the condition of the throat is, I find, often—indeed commonly—overlooked, although for successful treatment its recognition is a matter of the utmost importance. Whether there be symptoms suggestive of this condition or not, a glandular swelling at the border of the sterno-mastoid should suggest at once a careful inspection of the pharynx; and if the enlargement be recent, prompt treatment of the throat will in a short time cause the swelling to disappear. If the state of the fauces be overlooked or neglected, the enlargement of the glands may persist for months together, the swelling being more or less evident according to the degree of intensity of the pharyngeal disturbance. In such a state the glands have little power of resisting tuberculous infection; and as by their absorbent radicles they are in close connexion with the adenoid tissue in the naso-pharynx they are peculiarly open to invasion by the organism, and defend themselves feebly or not at all. Consequently if the state of the throat be disregarded, the glands may become the seat of tubercle, or possibly suppurate so that surgical measures may have to be resorted to; but the assistance of the surgeon is rarely required if the nature of the complaint be recognised in time. So long as the tumid glands retain their elasticity to the touch, and vary in size from day to day as the catarrh waxes and wanes, we may say positively that they are as yet unaffected by the tubercle organism and are still capable of returning to their original state. In such a case we may confidently expect that judicious treatment of the retro-pharyngeal catarrh will cause them to resume their natural size in the course of a few weeks.

The influence of post-nasal catarrh in promoting otitis by extension upwards of the derangement through the Eustachian tube into the middle ear is so much a matter of common knowledge and observation that this branch of the subject need not be referred to. I may, however, draw attention to the less recognised consequence of a downward spread of the catarrh and the irritation this further development is able to set up in the larynx and upper part of the trachea. The child becomes subject to attacks of violent cough which may come on at any time, but are especially liable to occur at night. He is not free from them during the day, but at night when he is put to bed and later while asleep he will often be roused by an attack of coughing which the domestic remedies employed have little power to restrain. The attack may last for 20 minutes or half an hour, and end in vomiting efforts in which a quantity of mucus is brought up. I have known such attacks to be mistaken for whooping-cough, especially as there may be some slight spasm of the larynx which produces an attempt at a crow, but the complaint is quite different in its symptoms from pertussis and may go on for months at a stretch in wintry weather unless the cause be recognised and appropriate treatment employed. Vomiting is only an occasional incident in the attack, but when it occurs the quantity of mucus which may be brought up by the retching efforts is sometimes surprisingly large. All this mucus has trickled down from the back of the nares and has been swallowed. When secretion is free the child may be noticed at intervals during the day to make swallowing efforts as the thick, tenacious mucus comes within reach of his muscles of deglutition. In most of these cases the patient's appetite is poor or almost completely lost, and this further symptom, itself a cause of disquietude, adds greatly to the concern of his friends. A further cause for alarm may sometimes be discovered in a staining of the mucus with blood or even a discharge of pure blood with or apart from the vomited matters. But there is no real cause for anxiety: the blood, like the mucus, comes from the back of the nose, and is no doubt a consequence of the increased strain upon the vessels set up by the retching efforts themselves. It is important to note that in spite of the urgency of the symptoms examination of the chest shows no sign of pulmonary catarrh or other indication of mischief in the lungs; and it was this absence of physical signs, conflicting as it does so curiously with the prominence of the cough, which first led me to look to the fauces for an explanation of the symptom. In cases where the cough is more than usually violent, especially if it be accompanied by any sign of spasm of the larynx, whooping-cough has to be excluded; but this is done by ascertaining the absence of an epidemic and noting the fact that other children of the family have remained unaffected although living all the time in intimate association with the sufferer.

In the treatment of these various disturbances the condition of the throat to which they all owe their origin must be remedied with as little delay as possible. In addition, the particular symptoms of each individual derangement must be the subject of special treatment.

For the throat affection local applications should be at once employed. These may take the form of drops instilled into the nostrils and allowed to trickle down into the naso-pharynx, or remedies applied directly to the fauces with a throat-brush. If the catarrh be very acute, with great irritability of the mucous membrane, we must be careful not to aggravate this condition by the use of too stimulating remedies. In such a case the throat should be painted several times a day with the glycerine of boric acid; or, if the child be old enough to follow directions, may be sprayed with a weak solution of tartrated antimony in water (gr. ¼ to the ounce) while the patient inspires deeply. By this means the first acuteness of the inflammation is quickly relieved, and the paint may then be made more astringent by combining the glycerine of boric acid with an equal proportion of glycerine of tannin. In cases where the painting cannot be carried out owing to the resistance of the patient and (especially) the want of determination on the part of the operator, some drops of a mild antiseptic solution may be instilled into the nostrils several times a day as the child lies on his back with his head supported by a pillow. Any weak antiseptic drug will do for this purpose, such as a solution of resorcin in normal saline (gr. v.–x. to the ounce) or of boric acid (gr. x. to the ounce of water), or of sodium bicarbonate (gr. xv. to the ounce). But any other remedy of this class may be used so long as it is not injurious to the stomach, for it is impossible to prevent a young child from swallowing the fluid when it reaches the fauces. In every case, however, where it can be done the throat-brush should be used, for the instillation of antiseptic drops is a far less efficient remedy than the other. As the redness of the pharynx fades stronger and stronger applications may be employed, for if the case be of long standing the mucous membrane is left flabby and relaxed and freely secreting. For such a condition pure glycerine of tannin may be used, or a paint made of gr. xii. of iodine and gr. xv. of iodide of potassium to the ounce of glycerine. This application may be flavoured by five drops of the oil of cinnamon or peppermint. A good astringent iron paint is made by adding one drachm of the stronger perchloride of iron solution to the ounce of glycerine, but this application should only be used after all trace of redness has disappeared; it is then a very efficient remedy. In cases where the anorexia has been complete the appetite usually returns when the flow of mucus into the stomach has been brought to an end. If, however, this result do not follow the symptoms rarely resists a good iron tonic, especially if this treatment be combined with bracing country air or a stay at the seaside, but change of air alone without special treatment of the throat is powerless to effect an improvement.

When there is active disturbance of the stomach with incessant vomiting no attempt should be made to administer food. All efforts to do so only aggravate the vomiting, however simple the food may be; milk especially in such a condition is an irritant poison whose use, by supplying more material for fermentation, can only prevent the disturbance from subsiding. The patient should be allowed nothing but water swallowed as hot as he can be induced to take it. Even this, however, will probably be returned immediately, especially at first; but this result is to be welcomed as it helps to clear the stomach of objectionable matters and may obviate the necessity of using the stomach tube. If, as may happen,

an odour of acetone can be detected in the breath, a hot solution of sodium bicarbonate may be used instead of the plain water, and six or eight ounces of the same solution may be injected under the loose skin of the back. This is the orthodox treatment and has the advantage, especially the hypodermic injection, of appearing to be an energetic proceeding, but I cannot say that it has seemed to me to be of much practical value. The severe forms of acetonæmia generally end badly and the milder cases usually recover whatever be the treatment adopted.

Other consequences of the catarrh quickly disappear when treatment of the throat is taken briskly in hand. Cough, however violent, soon subsides; spasm of the larynx rarely persists after the acuteness of the pharyngeal catarrh has been reduced; and subacute glandular enlargements in the neck are not slow to decline when the naso-pharyngeal irritation has been detected and subdued.

It is important to remember in the treatment of these complaints that we must not be satisfied by a mere temporary improvement, even if the symptoms completely disappear for the time, for in no case can this be accepted as a sign that the patient is definitely free from his troubles. In the treatment of catarrh affecting any tract of mucous membrane, in order to arrive at a permanent cure it is necessary for the medical attendant to bear in mind during convalescence the special sensitiveness to chills which still remains in the part lately affected. Catarrhs invariably tend to repeat themselves, and therefore relapses may be confidently expected unless special measures are taken to put a stop to this tendency to return. This can only be done by recognising the patient's susceptibility and taking steps to increase his resisting power and provide him with sufficient protection against sudden changes of temperature.

There is a tendency in the present day to make light of chills as a cause of disease, and to attribute all the disturbances which were formerly ascribed to this source not to the exposure but purely and simply to microbic agency. That noxious organisms may take a part in the process I am not prepared to deny, but at the same time I must protest against the doctrine that the influence of damp and cold and abrupt changes of temperature can altogether be left out of account. I have learned as a matter of clinical experience that relapses in these cases will continue to recur as long as a patient is neglected and exposed. If we allow such a child to go about with bare legs and cold feet, as is done so often, he remains weakly and suffers continually from catarrhal disturbances. If his legs are covered up with woollen stockings, if his feet are kept warm and such other precautions are taken as his known susceptibility may suggest, he will cease to suffer from these ailments and get well and strong. It is possible that exposure to cold may be hurtful by rendering the mucous surface a congenial soil for the action of organisms which, without this necessary preparation, would be incapable of harm; but whatever the explanation may be, of the fact I am convinced—viz., that to get and keep such children well we must keep them warm. The necessity of recognising this susceptibility in order to effect a permanent cure is a point upon which I have often insisted, but it is one which is too often overlooked even by the medical attendant. By the public it is invariably ignored; and in consequence when relapse follows relapse in any case of catarrhal derangement the relatives rarely fail to attribute the repeated and disappointing recurrence, not to their own ignorance or neglect, but to an assumed failure of their family adviser to supply a satisfactory remedy. But it is not the treatment which is usually at fault. This may have been judicious enough and successful again and again. The failure lies in the medical attendant's omission to insist upon proper precautions being taken in the matter of dress and general management to protect the patient against unnecessary exposure and the risk of further chills. Until this has been done the cure cannot be regarded as complete.

Queen Anne-street, W.

WINSLEY SANATORIUM FOR CONSUMPTION.—The proposed extensions at the Winsley Sanatorium will, if carried out, greatly improve the administrative block of buildings and provide better accommodation for the staff. It will also increase the beds for the accommodation of patients from 68 to 100.

A FURTHER CONTRIBUTION TO THE STUDY OF RHEUMATISM:

THE EXPERIMENTAL PRODUCTION OF APPENDICITIS BY THE INTRAVENOUS INOCULATION OF THE DIPLOCOCCUS.[1]

BY F. J. POYNTON, M.D. LOND., F.R.C.P. LOND.,
PHYSICIAN TO OUT-PATIENTS AT UNIVERSITY COLLEGE HOSPITAL AND THE HOSPITAL FOR SICK CHILDREN, GREAT ORMOND-STREET;
AND
ALEXANDER PAINE, M.D., B.S. LOND.,
DIRECTOR OF THE CANCER HOSPITAL RESEARCH INSTITUTE.
(From the Research Laboratories of University College Hospital and the Cancer Hospital Research Institute.)

The Source of the Infection.

THE first step in this communication is to indicate accurately the source of the infective agent with which our results were obtained.

A boy, aged 14 years, previously healthy and with a good family history, came to University College Hospital in August, 1911, suffering from a first attack of acute rheumatism of five days' duration. It commenced with pain in both knees and ankles and later in the left shoulder. The temperature was 100·5° F. and the pulse-rate 100 to the minute. Both knee-joints were tender and full of fluid, and the other joints named above were painful. For 24 hours an apical systolic murmur was faintly audible, but this disappeared and the boy made a rapid and complete recovery. He was treated with salicylate of soda. The only point at all unusual in this case was the excess of fluid in both knee-joints, the right one being distended. Mr. C. E. Shattock, acting house physician, tapped the joint for us, and a greenish fluid, which coagulated and contained some fibrinous shreds, was obtained. From this a diplococcus was isolated and grown in pure culture and is the infective agent which we have used for the following experiments.

The Investigation.

The animals used for experimentation were rabbits, and we would lay special stress upon the point that we used consistently for the first time young ones of some six to seven weeks of age. All the injections were made from bouillon cultures into the auricular veins. The first animal injected with a large dose died from general pericarditis. The second was six weeks old and received ½ c.c. of a bouillon culture. Multiple arthritis followed and mucous diarrhœa, the animal dying from an intussusception of some days' duration. In passing, we would comment upon this occurrence of acute intussusception in two animals as a sequel and possibly a result of the infection. A pure culture of the diplococcus taken from the joint of this animal was used for the third rabbit. This was seven weeks old and was inoculated on Sept. 2nd with 1 c.c. of a bouillon culture. Monarthritis of the left knee-joint developed with general illness and diarrhœa, and death occurred on the third day. The post-mortem examination showed that *for 1½ inches in the middle two-fourths of the appendix* there was acute inflammation. The left knee-joint showed the usual early synovitis. The liver showed fatty areas. The spleen was slightly enlarged and firm. The kidneys were not remarkable. There were no petechiæ and no post-mortem staining; the heart was not opened, but there was excess of fluid in the pericardial cavity. The diplococcus was recovered in pure culture from the left knee-joint and the heart's blood. The appendix was clearly inflamed and the mucous membrane was swollen and red. A small piece was excised for histological investigations.

[The rabbit was shown, with histological sections illustrating the diseased condition of the appendix and the presence of the infective agent in the blood-vessels in the submucosa and in the mucosa.]

The details of the histological examination were as follows. The muscular and serous coats of the bowel were healthy, but the mucous and submucous layers showed extensive necrosis. There was destruction of Lieberkühn's follicles and of the lymphoid tissue. The basal vessels of the submucosa were engorged with blood, and numerous diplococci could be seen

[1] A communication read before the Pathological Section of the Royal Society of Medicine on Oct. 17th, 1911.

both in the vessels and in the tissues of the mucous and submucous coats. The bacillus coli had also invaded the necrotic area. Lastly, there was a slight fibrino-cellular exudation into the lumen of the gut.

Although this was the third rabbit alluded to in this paper, four others had been inoculated and had developed multiple arthritis but no appendicitis; but one more in this series—that is, the fourth mentioned here—developed in addition to multiple arthritis in both elbow-, knee-, and carpal joints some diarrhœa, and was killed when *in extremis* on the fifth day.

The *middle two-fourths of the appendix* showed small opaque areas, deep-seated in the substance of the wall, and this part was swollen and firm to the touch. The blood-vessels in this situation were engorged. On opening the appendix a mucoid fæcal-stained fluid escaped, and at one spot on the inner surface a reddened depressed area of the size of a hempseed was visible. The opaque areas seen from the external aspect were still more obvious from within. At the junction of the appendix with the cæcum there was an enlarged lymphatic gland, and there was excess of fluid in the peritoneal cavity. The spleen was slightly enlarged but not soft, the liver was dark and firm, and the kidneys were pale. The heart was dilated and full of blood; there was no pericarditis or endocarditis. The lungs were congested, and there was excess of fluid in the pericardial cavity. A pure culture of the diplococcus was recovered from a knee-joint. The depressed area in the appendix proved to be an acute ulcer, a section of which is under the microscope and the histology of which was as follows:—

The chief changes are visible in the mucous and submucous coats These are of two kinds; in some places there is disappearance of the lymphoid tissue with a tendency to necrosis, in others a proliferation of the connective tissue elements pointing to the first stage towards a fibrosis. Diplococci were not demonstrated in the portion of the tissue examined, in which reparative processes were just commencing.

In the area of ulceration there is local necrosis of the mucosa and submucosa with destruction of the epithelium of Lieberkühn's follicles and the lymphoid tissue. The muscular and serous coats are not involved and form the base of the ulcer. The connective tissues bounding the necrotic area show commencing proliferation.

Another series of inoculations was made from the culture taken from the first rabbit that had suffered from acute appendicitis, and one of this series was killed when *in extremis* on the third day. During life arthritis of both knee-joints had shown itself and there was some diarrhœa with general illness, the result of the inoculation. On opening the abdomen a condition was observed the nature of which we must ask to be accepted from our description because in the process of preservation it could not be produced. The *middle two-fourths of the appendix was ballooned* and in the walls were small opaque areas not so extensive as in the preceding case, and situated chiefly along the mesenteric attachment. The viscera showed no noteworthy features and both knee-joints were in a condition of early arthritis. The diplococcus was recovered from one of these in pure culture.

The histology of this condition shows the earliest stage of an infection by the blood-stream. The first changes appear in the mucous and submucous layers, but chiefly in the lymphoid follicles of the latter. Small foci of polynuclear cells can be seen here and there surrounding the minute blood capillaries, and every stage of inflammatory change can be traced up to complete destruction of the normal tissue, ending either as necrosis or connective-tissue proliferation. Diplococci are visible in various stages of destruction within the phagocytic cells, according to the stage of inflammatory reaction.

The last series that has been inoculated consisted of three young rabbits, seven weeks old, which were injected intravenously on Oct. 6th with very small doses (0·25 and 0·1 c.c.) of a bouillon culture from the knee-joint of the preceding rabbit with appendicitis. All developed arthritis and one diarrhœa; this one died on the ninth day. There was marked arthritis of the left carpal joint and slight arthritis of both knee-joints, the synovial membranes of which were red and congested. About half an ounce of turbid fluid was removed from the peritoneal cavity, and the serous membrane showed early inflammatory changes. *The appendix at the junction of the last one-fourth with the first three-fourths* showed an opaque area deeply seated in its wall. The blood-vessels were congested. As regards the other viscera, there was no noticeable feature, except that the spleen appeared to be unusually small. Cultures from the left carpal joint and peritoneal fluid gave a pure growth and films also showed that the diplococcus cultures from the blood were negative. We would emphasise the absence of the bacillus coli in the films and cultures of the peritoneal fluid. Thus it will be recognised that in this case, which had lasted nine days, some peritonitis occurred and living diplococci were present in the peritoneal fluid.

Summary of Histological Details.

To summarise our histological results we would point out the occurrence, first, of a very early appendicitis; secondly, of a severe appendicitis; thirdly, the formation of an ulcer; and fourthly, the occurrence of peritonitis as the result of local deposits of the diplococcus intravenously injected. We would also express our belief that in human appendicitis, apart from the complicating event of a concretion which we know is not a constant occurrence, the histological changes might be well explained by our results. The early cases with their focal deposits in the submucosa and mucosa, showing cell proliferation and little necrosis, might well if they had been more prolonged in duration have produced sclerosis of the wall such as occurs in chronic human appendicitis. The acute case with much necrosis would represent the virulent human condition. Lastly, the ulcer, had it healed and been rather more extensive, would have produced the stricture so often seen in man.

The occurrence of an early peritonitis without perforation throws light upon malignant human appendicitis.

The rapid destruction of the diplococci by the tissues is a most interesting event, fully bearing out our previous experiences as to this micrococcus, which have led us so repeatedly to explain the difficulty of its isolation during life.

The enlargement of the lymphatic gland at the base of the appendix is paralleled in human appendicitis.

In none of these cases nor in the 24 rabbits inoculated in this research was there a single abscess on the viscera.

Adrian's Researches.

In so far as these results are the outcome of infection with a micro-organism obtained during life from rheumatic arthritis, and a micro-organism, too, capable of reproducing a similar arthritis, they are, we believe, a new contribution to the subject of experimental medicine, and a new fact in the pathology of the important condition of appendicitis. If, however, we were to claim that the wider question of the possibility of appendicitis arising as a local result of a general blood infection had not been realised and experimentally investigated before, then we should do a gross injustice to others. Absolutely independent as these investigations of ours have been, we must refer to Adrian's paper published ten years ago[2] upon the occurrence of appendicitis, both clinical and experimental, as a result of general infection. This author in a masterly investigation refers to this production of appendicitis in rabbits by the intravenous injection, not only of streptococci, but also staphylococci, typhoid bacilli, pneumococci, and the bacillus coli. In the pneumococcal investigation he demonstrated the micrococcus in the wall of the appendix, and his microscopic section of the inflamed appendix resulting from a streptococcus infection is in accord with the histological results that we have shown. He gave no details of an ulcer formation or of another lesion such as arthritis, or of the condition of the peritoneal fluid, nor does he mention the source of the streptococcus, but these points are of secondary importance compared to the general question with which his contribution was concerned.

In his paper Adrian gives many references to the work of others upon the general question of the origin of appendicitis from a general blood infection or local injury. Roux and Josué Roger, Beauserrat de Rouville, Gouget, and others have investigated in various ways upon this question, and Adrian's paper reviews this work.

Concluding Observations.

We would make the following concluding observations:—

1. There seems to us no doubt that in these cases acute appendicitis resulted directly from an intravenous inoculation of a diplococcus obtained during life from an acute rheumatic arthritis, and it appeals to us as interesting that it was the only obvious alimentary lesion, a point which Adrian noted in his cases.

[2] Mitteilungen aus den Grenzgebieten der Medizin und Chirurgie 1901, p. 407.

2. The conditions that were produced were of varying severity.

3. In each case the animal was young; heretofore we have not observed such a condition in the older animals. This may or may not prove to be an accurate observation.

4. The condition arises without the presence of any concretion or foreign body in the appendix, and commences deep in the wall of the appendix. This later point militates, in our opinion, against the view held by Aschoff that in human appendicitis the disease starts from within the lumen of the appendix.

5. It is interesting that the middle part of the length of the appendix is affected, a position in which a stricture is so often found in man.

6. In one case early peritonitis with living diplococci in the peritoneal fluid occurred, although there was no perforation—a point of much importance in its bearing upon the pathology of human appendicitis.

7. The ballooning of the affected area of the appendix in one case suggests the probability that in man some such loss of tone favours stagnation of secretions and contents and the formation of a concretion.

8. The association of arthritis, mucous diarrhœa, and appendicitis is of interest in its bearing upon the difficult question of auto-intoxication from the bowel in the human subject as a cause of arthritis. It suggests that rather than this being the primary factor, the probability is that all the lesions may be the result of some primary cause circulating in the blood stream and determining to these various positions.

9. We do not assert for one moment that the only cause of appendicitis is this diplococcus. Adrian's investigations and those of others are sufficient evidence, quite apart from clinical experience, to prevent us falling into this error.

10. Whether or not these results favour the widely held view of a relationship between acute rheumatism and appendicitis must depend upon the significance that is attached to this diplococcus and the degree of parallelism that exists between human disease and experimental infection.

NOTES ON THE ETIOLOGY OF SCARLET FEVER.

BY R. W. C. PIERCE, M.D., B.SC. LOND.,

MEDICAL OFFICER OF HEALTH FOR GUILDFORD; MEDICAL OFFICER, GUILDFORD, GODALMING, AND WOKING JOINT HOSPITAL BOARD.

IN these notes no attempt will be made to deal exhaustively with the etiology of scarlet fever, but a short description will be given of a series of cases admitted to the Guildford Joint Isolation Hospital, which tend to confirm the opinion I have long held, that a fair proportion of the patients admitted into our fever hospitals as suffering from scarlet fever, although presenting signs which are indistinguisable from those of true scarlet fever, have not in fact necessarily contracted the infection from a previous case of the disease.

It has been asserted by medical officers of health for urban districts that as, perhaps, 70 per cent. of cases of scarlet fever reported were traceable to previous cases, it followed that the remaining 30 per cent. originated in a similar manner. This reasoning may be more or less justifiable in a congested area where the possibility of infection by direct or indirect contact is difficult to exclude, but it cannot logically be applied to sparsely populated districts, where such contact can often be excluded with every degree of probability. Moreover, in such districts the accumulated evidence of the remaining 30 per cent. is so strong as to force the conclusion that sporadic cases of scarlet fever arise without reference to a previous case. It is obviously only in thinly populated districts, if at all, that this possible mode of origin of scarlet fever can be proved. If a single origin for scarlet fever is insisted upon it would be illogical to deny to such infectious diseases as erysipelas, pneumonia, and cerebro-spinal fever an origin apart from previous cases.

It may, of course, be objected that cases notified as scarlet fever, in which there has presumably been no direct or indirect contact with a previous case, are either not cases of scarlet fever at all, or that the previous case did exist but was not traced. The first objection carries with it the responsibility of laying down the pathognomonic signs of scarlet fever. My contention is that sporadic cases of an exanthematous disease arise in which an origin from previous cases may resonably be excluded, but which present signs which are indistinguishable from those of true scarlet fever. In view of the well-known ambiguous character of many attacks of this disease, it would probably be a relief to most medical officers of isolation hospitals to have cases sent in which showed a puncto-erythematous rash, a congested throat, and elevation of temperature, followed by a distinct peeling of the tongue, and subsequently of the hands and feet. The following two cases exhibited these signs, and yet contracted second attacks after admission to hospital.

CASES 1 AND 2.—The patient in Case 1, a boy, aged 5 years, was admitted into hospital on April 17th, 1911, with a temperature of 100·4° F. and a pulse of 104, a peeled tongue, congested throat, and what seemed to be the remains of a puncto-erythematous rash on the trunk, and especially in the groins and upper part of the thighs, but which was scanty on the limbs. He had impetiginous sores on the cheek and left ear. The onset was stated to have occurred with malaise on the 14th, sore throat on the 15th, and rash on the 16th. He was said to have had the sores on the face for two months, and a baby brother had had impetigo of the scalp for about the same time. No previous cases had been reported in the locality for eight months, and then only one isolated case. On April 19th a note was made that the tongue had a distinctly peeled appearance, and that the rash was still present in the groins. On May 3rd—i.e., in the third week—there was definite peeling on the hands. The soles of the feet showed dry powdering only.

On the same date (April 17th) was admitted his brother, aged 13 years (Case 2), who showed on admission a flushed face and a puncto-erythematous rash on the trunk, a very congested throat with punctation of the soft palate, temperature 101° F., and pulse 104. The date of onset was given as the 15th (one day after his brother); there were sore throat and headache on the 16th, and a rash on the 17th. On the 19th the throat was very congested and swollen, the rash was well out, chiefly on the trunk, but extending to a slight extent on to the backs of the hands and feet. The tongue was peeling distinctly. On the 20th the rash, which was now mostly punctate, was still well out on the trunk, and especially in the groins. There was pinhole peeling on the trunk, and at the end of the second week marked peeling of the palms.

The boys had been placed in the scarlet fever ward with only one other patient. Up to this time no doubt had been entertained but that both were suffering from mild attacks of scarlet fever. On May 1st, however, the elder boy, after an onset with sickness, headache, and sore throat, developed a still more general and typical rash, the hands distinctly peeling at the same time from the first attack. His temperature rose to 101·8° on May 2nd, and did not become normal until the 11th. On May 4th the tongue had peeled and was raw-looking, and it subsequently became ulcerated. On the 8th there were rheumatic pains in the wrists, which extended to the elbows. The second attack was altogether more severe and typical than the first, but in spite of this it was considered to be one of the relapses which occasionally occur. On this account, and the ward being practically empty, the younger brother was not removed.

The next thing that happened was that the latter on May 23rd developed a very typical attack of scarlet fever, with a temperature of 103·8°, followed by general peeling, double otorrhœa, and some albuminuria. On June 12th the hands had finished peeling, and the feet about half-finished, for the second time, both being more copious than on the first occasion. The ward had been empty of other patients since May 13th, so that it is highly probable that his secondary infection was contracted from the elder brother.

There is no doubt that the second attack in both cases was true scarlet fever, and as it would have been an extraordinary coincidence that both were relapses, it is probable that the first attacks were due to a systemic infection, possibly by streptococci from the impetiginous sores.

The following series of cases point to the same conclusion. The notes taken were not very complete, as there was no intention at the time of publishing them. All were sporadic cases without known antecedent or subsequent cases in the several localities:—

CASES 3-6.—The patient in Case 3, a girl, aged 12 years, was admitted from an isolated cottage on Jan. 9th, 1911, with a temperature of 103·4° F., which fell gradually to normal by the 16th. There was a history of an onset on the 7th with sore-throat; sickness all day on the 8th and rash on the morning of the 9th. The case was typically scarlet fever in respect of the rash and the red and swollen throat. On the 13th the rash was fading from the trunk, but was still very visible on the hands and feet. The tongue had peeled. On the 19th there was pinhole peeling above the pubes. On Feb. 14th the hands had not finished peeling, the toes had commenced to peel, and the soles had not completed peeling on Feb. 29th. This child had not been out of the house since Jan. 1st. On inquiry at the home two other children were found to be affected with impetigo of the face.

On Jan. 25th the mother and two children were admitted to hospital. The mother on admission had no temperature and no rash. There was history of an onset with malaise on the 17th and a scarlatiniform rash, mainly confined to the trunk, on the 18th.

One of the children, aged 2 years, had impetigo and a discharging ear, and the second child, aged 12 months, had on admission swollen submaxillary glands, a temperature of 103·4°, which gradually declined to 99° on the 30th and then rose, with morning remissions, to 102·4° by the evening of Feb. 4th.

Neither the mother nor the two young children showed more than powdery peeling. It appeared that these two children had a slight rash within two or three days of each other during the last week of the year, and that another child was sent home from school with impetigo before Christmas and also had a general rash.

In this series of cases, again, there is a strong presumption that they were all associated with the impetigo, as no previous cases had occurred in the school or locality. All the four cases notified were probably of the same nature, as they were together during the six weeks' detention, and the first case at any rate was indistinguishable from a typical attack of scarlet fever.

Another similar case follows:—

CASE 7.—The patient, aged 9 years, was admitted on April 3rd, 1911, with a temperature of 102·2° F., which gradually fell to normal on the 6th. There was a history of onset on the 1st, and a rash next morning. On admission there was a good puncto-erythematous rash, a red and swollen throat, and a whitish furred tongue. On April 4th there was a deposit of albumin in the urine, and on the 5th the tongue had peeled, and there was glandular swelling on one side of the neck. On the 19th he was powdering freely on the trunk, and the palms and soles had finished peeling by May 9th. It was found that a child at home had at the time of admission impetigo of the scalp and that the mother had whitlows on both hands.

Another isolated and similar case is next given:—

CASE 8.—The patient, aged three years, admitted on Dec. 6th, 1907, with a history of onset on the 3rd, sickness and sore throat on the 4th, and a rash on the 5th on the chest extending to the legs and arms. On Dec. 28th his hands were peeling distinctly. This child had not recently been outside the premises, and there were no other children in the home. He had, however, communicated through the palings at the back with the next door children, who were at the time affected with impetigo.

One more similar example may be cited:—

CASES 9 AND 10.—A patient, aged 3 years, was admitted on Sept. 3rd, 1908, with a temperature of 99·5° F., which became normal next day. There had been sickness on August 30th, and a rash and sore throat on Sept. 1st. A sister, aged 7 years, was admitted at the same time with an identical history. On admission there was a fading punctate rash on the body and limbs, but none on the hands and feet. The tongue had a peeled appearance. The throat was a little congested and there was some exudation on the tonsils. On Sept. 12th there was peeling on the trunk and early peeling on the hands.

The patients' home was an isolated keeper's cottage. There were four other children, and three if not all four of these were at the time suffering from impetigo contagiosa. The children were detained in hospital for eight and 11 weeks respectively, the latter on account of rhinorrhœa.

Some cases found associated with purulent conditions other than impetigo contagiosa may now be mentioned.

CASE 11.—The patient, aged 21 years, who stated she had had scarlet fever when five years of age, was admitted to the isolation hospital on Feb. 16th, 1910. The onset was on the 14th with nausea; a rash appeared on the 16th. She was suckling a four months old child. On admission the rash was scarlatiniform and was general, including the backs of the hands and feet. The throat was very red, the tongue furred but cleaning at the edges. One breast was very tender and swollen. On the 18th the rash was more out on the thighs and fading from the trunk. The breast was incised on the 23rd and a quantity of pus found. On March 22nd the palms were noted to have peeled over half their extent, and there was peeling on the toes.

CASES 12 AND 13.—A patient, aged 11 years, was admitted on May 27th, 1911, with a copious scarlatiniform rash, slight throat symptoms and temperature, and with an abrasion on the arm from a fall, which was suppurating and had been poulticed by the mother. She subsequently developed superficial abscesses in the armpits.

The girl's twin sister was taken ill four days after the other, and was admitted with similar signs on May 28th, and a temperature of 103° F., which did not become normal until June 5th.

On both these children the peeling was exceptionally marked and early, as there was pinhole peeling over the pubes on May 27th and June 2nd respectively; free peeling on the hands on June 2nd and 3rd, and by June 8th and 9th the hands had finished peeling in large thick sheets; and by June 10th and 11th the feet had finished in a similar manner. In these two cases the amount of rash and peeling was out of proportion to the throat condition and the constitutional disturbance.

CASE 14.—The patient, aged 3 years, was notified on April 23rd, 1909, and nursed at home. The child had a good scarlatiniform rash, but did not complain of sore throat, which only showed slight congestion. She had a suppurating sore on the heel. She was feverish and drowsy on the 22nd, and a very irritable rash appeared on the trunk the same day, and on the legs and arms on the 23rd. The subsequent peeling was definite on the hands, and there was suppuration in both ears.

CASE 15.—The patient, aged 3 years, living in a large house, had an onset on June 13th, 1910, with sickness. There was a dirty congested throat, and a scarlatiniform rash appeared on the 14th. The child had an abrasion of the chin on the 11th, which suppurated. There was subsequently a troublesome purulent vaginitis. There was extensive peeling. She had not been out except with the nurse. The mother looked after the patient at home and herself fell with similar symptoms on June 25th, which ran the usual course.

CASE 16.—The patient, aged 12 years, was admitted on August 27th, 1909, with a temperature of 101° F. which became normal on Sept. 1st. There was a history of having been confined to bed for three days with a painful stump of leg which was suppurating. There had been malaise and sore-throat on the 26th and rash on the 27th. On admission the tongue was furred, the throat a little red, the rash general except on the hands and arms, fairly profuse on the trunk and thighs, none on the face. On the 29th there was still rash on the trunk, which was now punctate, very little on the arms and legs, and a few specks only on the backs of the hands and feet. The boy, who had been admitted into the scarlet fever ward, developed a typical attack of that disease on Sept. 5th, the rash and the throat symptoms being more marked than on the first occasion.

Dr. J. C. Thresh, in his annual report for the Chelmsford rural district for 1910, refers, in connexion with some cases of scarlet fever, to an interesting observation by Mr. H. Cardin of Stock, which tended to throw light upon the origin of sporadic cases. One of his cases was associated with a suppurating gland and another with a suppurating scald, and Dr. Thresh states that he himself has also noted some sporadic cases in which an examination revealed some purulent condition.

In view of the fact that the streptococcus of Fehleisen has been isolated from the sores of impetigo, it is not improbable that if some of the exudation finds access to the tonsil it should set up there an inflammation with systemic absorption corresponding to that which occurs in epidemic scarlet fever. Conversely, we may argue that if streptococcal organisms are capable, when introduced into the throat, of giving rise to an illness indistinguishable from the true or common scarlet fever, the latter disease is probably due to a streptococcus. Judging from the first two cases mentioned and Case 16, the one variety does not confer immunity against the other. Cases, however, of a simulating disease may often survive the usual detention in a well ventilated and managed scarlet fever ward without contracting the true disease, so that their freedom from a second attack is no proof of the genuineness of the first.

Another disease which is usually streptococcal, and which is supposed to induce special liability to an attack of scarlet fever, is puerperal fever. The occurrence of many of these cases without exposure to a previous case of scarlet fever suggests an autogenous origin.

Similarly the cases of so-called surgical scarlet fever following burns and other wounds in hospital wards, where there have been no previous cases of the disease, could be accounted for in the same manner. Cases not infrequently occur following tonsillotomy, the patients on admission to the isolation hospital showing a sloughing surface to the tonsil and the signs of a mild attack of scarlet fever. Of two cases of this character recently admitted to the isolation hospital neither developed a second attack during the usual detention in the scarlet fever ward.

The most important thing to decide in connexion with these cases is whether they are infectious. Apparently they are, though to a less extent than in the case of the common epidemic form.

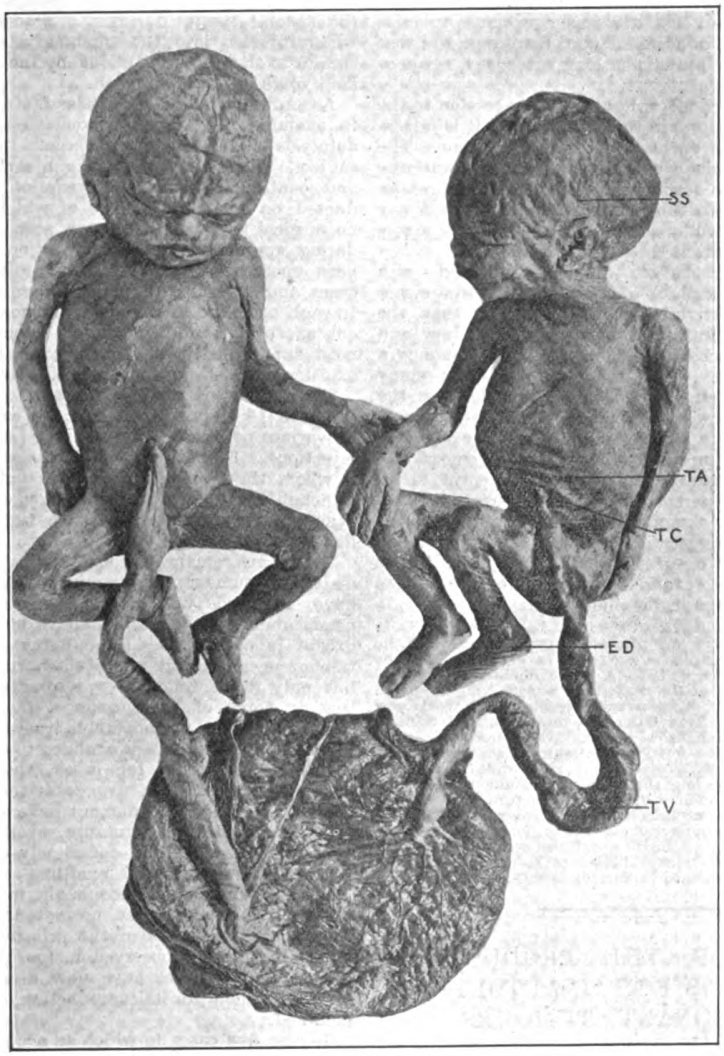
Besides the groups of cases already dealt with in which there were obvious sources of pyogenic organisms, other sporadic cases frequently occur in rural districts in which there is no such source obvious, but which may still possibly be accounted for in a similar manner, such sources being more common than those of the infective agent of epidemic scarlet fever. In any event, the numbers of these cases is so considerable as to warrant the conclusion that a previous case of scarlet fever is not a necessary antecedent, although they present all the symptoms, usually in a modified degree, of the true disease.

If we recognise only the usual epidemic type as true scarlet fever, then it is unsafe definitely to diagnose as scarlet fever cases which present peeling of the tongue a few days following the appearance of a rash and sore-throat, and which shows marked peeling of the hands in the third week—signs which are generally considered pathognomonic of the disease.

The occurrence of associated purulent conditions in the cases mentioned is in all probability more than a coincidence, because their frequency is much greater than in the case of epidemic scarlet fever, and, moreover, no other likely origin could be traced for the cases. To make the proof complete it would no doubt be necessary to show that the percentage of these cases which arise in patients either suffering themselves, or who have been in contact with those suffering from some purulent condition, is greater than that of the accidental association of these conditions with ordinary scarlet fever.

Guildford.

DEVIZES COTTAGE HOSPITAL.—At Devizes on Oct. 18th Lord Radnor formally laid the foundation stone of the "King Edward VII. Hospital Extension," which is to be added to the Devizes Hospital. There was a large attendance, and the ceremony was carried out with full Masonic ritual. The extension will comprise the addition of a children's ward, and the practical reconstruction of the present administrative block, an operating theatre fitted up to modern requirements, and an X ray room.



TORSION OF THE FUNIS AS A CAUSE OF DEATH OF TWINS.

BY H. A. LEDIARD, F.R.C.S. ENG.,
SURGEON TO THE CUMBERLAND INFIRMARY.

AMONG the causes of death of the fœtus torsion of the cord is always named, but it seems that Martin, Ruge, Schauta, and most modern observers regard exaggerated torsion of the umbilical cord as a post-mortem occurrence, resulting from the great mobility within the uterine cavity of a fœtus that has died from the fifth to the seventh month of pregnancy.[1] According to Tarnier and Budin (1886), torsion of the cord generally has no bad effect, but they admit that there are cases recorded where the vessels were completely obliterated. It is at the umbilical extremity of the cord that exaggerated torsion is found most frequently, and it is much more rare at the placental insertion; but sometimes it is placed in the centre or middle of the cord. The old view was that in the majority of cases exaggerated torsion caused death of the fœtus, but the modern text-book seems to regard torsion of the cord as a matter of small concern, so that there is but little to extract when information on the subject is sought for.

The example now published is fairly complete in the details required for enabling judgment to be formed, because as soon as the pregnant woman lost the sense of movement she reported the occurrence, and ten days later the twins were expelled. Galabin and Blacker[2] state that torsion of the funis may be produced either after the death of the fœtus or during its life, but they admit that by causing obstruction of the vessels it may lead to the death of the fœtus. "In individual cases it is difficult to determine whether torsion is the consequence or the cause of the death of the fœtus."

The case shows that twins (females) were equally advanced in development up to the sixth month, that the death of one took place a short time before the death of the other, and that the fœtus dying first had the cord twisted at the umbilical insertion up to obliteration. The mother had had two living children previously and was familiar with the sensations of pregnancy. She counted from June 3rd, and felt movement up to the night of Nov. 12th. She was occupied in "ironing" on the 10th, and felt tired after, and on the 16th (the day she was seen) she stated that she felt the abdomen "heavy," "much heavier" than it had been. No movement was detected with the examining hands and no sound was heard with the stethoscope. There was no vaginal discharge. Several examinations confirmed the probability of a dead fœtus, and it was agreed that the womb should be cleared out. On Nov. 23rd a large dilator was inserted into the cervix, followed up by a finger, and the amnion was ruptured. Some hours later (about eight) twins (both dead) were easily and spontaneously expelled.

Reproduction of a photograph showing the difference between the twin fœtuses. SS, Shrunken scalp TA, Torsion of abdominal wall following TC, torsion of cord. ED, Epidermis detached from leg and foot. TV, Thrombosis of vessels of cord and distension of cord; colour dark.

The twins were both female and presented different appearances. It was seen that the cord of one fœtus was twisted close to the body in such a way that it was reduced to the size of a pencil. The cord beyond was swollen to a considerable size in comparison with that of the other fœtus. The fœtus with the twisted cord was somewhat smaller than the other, the skin was peeling, and death had taken place not long before expulsion. Both fœtuses were in the first stage of decomposition—viz., peeling of the epidermis—but the fœtus with the twisted cord was more advanced in the process than the other. The scalp was looser and the body and limbs were of a darker colour. The skin of the abdomen at the umbilicus showed wrinkles and an attempt to follow the torsion of the cord. The skin of the other fœtus at the same spot was without wrinkles.

The inference drawn is that both fœtuses were developing equally, but that one began to turn and the cord became strangulated at the navel; circulation being cut off the fœtus died. The death of the first was not noticed by the mother, because the movements of the second fœtus continued. Then the placental circulation became interrupted and the second fœtus died, possibly from thrombosis, on Nov. 12th. There was probably not more than seven to ten days' interval between the death of the one and that of the other, judging by the appearance of the fœtus which died last.

There seems to be no other obvious cause for the death of the twin fœtuses except the torsion of the cord of one. There was no syphilis in question, and the parents were healthy. There had been a miscarriage at five months eight years

[1] Hirst, 1909.
[2] The Practice of Midwifery, 1910, p. 538.

previously. A girl born later had died from tuberculous peritonitis, but a boy aged 5 was alive, though frail looking.

The photograph taken shortly after the expulsion shows the cords of the twins inserted at opposite points in the placenta, the distension of the cord of the fœtus and the sharp twist at the navel, and the wall of the abdomen wrinkled. Comparison of the bodies shows the skin of the scalp and body more lax than the skin and scalp of the other fœtus, but the skins of both are seen in peeling stage. The appearances are consistent with the story of the mother, and it would hardly be expected that decomposition would be further advanced at the end of 11 days after cessation of movement in utero. If, therefore, the putrefactive changes were not widely different in the twins and were only a degree more in one than in the other, and one had a twisted cord while the other had not, it seems reasonable to infer that the fœtus with the obliterated cord died first, and that the death of the other followed not long after, say, seven or eight days or even less.

Tyler Smith and indeed all writers attribute torsion to the movements of the fœtus, and in the case of twins it is fair to suppose that there might be less space for movement. The exact position of the twist would depend upon intra-uterine conditions impossible to formulate. The cord may get an obliterating twist close to the body of the fœtus, or it may become equally obliterated by a twist somewhere in its course away from the fixed points at the placenta and navel.

The silence of text-books on torsion of the cord—with the exception of those authors quoted—suggests that either the question is too trivial for mention, or that the cases of death from intra-uterine torsion are few and far between. Then comes the statement that torsion is a post-mortem occurrence. That this may be so in many cases no one would question, but I do not consider that the case now recorded belongs to that class. Possibly few cases are on record where twin fœtuses grew equally for a certain time, and then one dying with a twisted cord caused the other to die also. I had a few years ago a twin birth, one child living and apparently healthy, whereas the small dead fœtus was quite black and shrunken. Syphilis was the reason, because the living child was the object of much anxiety and throve well on grey powder. The twins in the case recorded were not examined post mortem, and the appearances are those seen in the photograph.

Bibliography.—Transactions of the Obstetrical Society, vol. x., p. 94: "Dr. Rasch exhibited a fœtus and placenta (5 months?) in which the cord was obliterated by twisting. Close to the navel of the fœtus the funis had the appearance of firmly twisted, thin cord of the thickness of a crow quill." Transactions of the Obstetrical Society, vol. xli., p. 51: "Dr. Westmacott exhibited a remarkable specimen of 'corkscrew funis'" (no details given). Transactions of the Obstetrical Society, vol. xxxi., p. 164: "Dr. M. Handfield-Jones showed specimens of curious twistings of the cords around fœtal limbs lashing them together, the funis in one case being dragged out into a thin, ribbed-like ligature, and it was a matter for surprise how the circulation could possibly have been carried out through such a flattened structure." Tarnier et Budin, vol. ii., p. 362: "The labours of Martin, of Ruge, and of Schauta show that in the great majority of cases it is not the exaggerated torsion of the cord which has brought about the death of the fœtus." The quotation from Hirst already alluded to seems somewhat too sweeping in view of the reference to Tarnier and Budin.

Carlisle.

THE ACTION OF THE PRODUCTS OF HOMOGENEOUS FŒTAL AUTOLYSIS ON MALIGNANT TUMOURS IN MAN.

PRELIMINARY NOTE.

BY DR. G. FICHERA,

SURGICAL INSTITUTE OF THE ROYAL UNIVERSITY OF ROME (PROFESSOR DURANTE, DIRECTOR).

Translated from the Italian by ALEX. R. COLDSTREAM, *M.D. Edin., F.R.C.S. Edin., Florence.*

THE study of the biology of embryonic and neoplastic inoculations, which I undertook some time ago, has afforded me various results on which are founded the researches here detailed.

1. The observation of the extreme rarity of spontaneous malignant tumours in young rats. This fact recalls the absence, or the very exceptional occurrence, of simple neoplasms or specific tumours, as epitheliomas and sarcomas, in the newly born and young subjects, and leads one to believe that, in the early epochs of life, the factors necessary for the genesis of malignant tumours do not exist.[1]

2. The fact of the noteworthy and frequent resistance to the inoculation of neoplasms which rats acquire by previous injections of embryonic or fœtal tissues. Such a fact suggests the existence of some substances contained in, or originating from, the inoculated fœtal tissues which, on diffusion, render the subject immune to subsequent attempt to reproduce malignant growths.

3. The demonstration that homogeneous embryonic or fœtal tissues, when subjected to autolysis, by hypodermic injection or by local application, bring about the involution of the inoculated neoplastic elements, which always reproduce themselves and prove fatal. This fact strengthens a belief in the existence of substances which are generated by the special tissues during the process of autolysis, which when injected into the organism act on tumours in a way similar to that brought about by the preventive injection of embryonic or fœtal emulsion.

Accordingly, guided by these facts, I have deemed it well to examine the effect of homogeneous products of fœtal autolysis in cases of malignant tumours in the human subject. The observations, begun early in September, 1909, and continued without interruption, have been all conducted on inoperable cases, of which only 7 had received no surgical treatment, although seen by the ablest and most daring surgeons, when no operation was possible; 29 had been operated upon, even repeatedly, including recurrent cases and several with multiple and voluminous metastases. In each case the histological diagnosis was confirmed without exception, and the clinical evolution was followed up, both anatomically and microscopically, by means of the excision of small portions, repeated even eight times.

The number of cases submitted to the injections was 36. Of these, 14 stopped the treatment early by their own desire for various personal reasons, having received from three to ten injections. From the other 22 cases we must subtract four, in whom the treatment has been only recently begun, and, although in three of these the first subjective and objective symptoms of improvement have begun, one cannot as yet depend on any result.

There thus remain for consideration 18 patients affected by malignant tumours, varying in substance and position, who have followed up the treatment with regularity and perseverance. Of these, eight have derived no marked benefit, except in a few cases some delay in the progress of the tumour or an initial improvement of the general condition, but only to be followed by a progressive deterioration, so that in three of these cases a fatal result occurred, an inevitable event in inoperable tumours, and considered as imminent in all the cases confided to me.

As for the other ten cases, the beneficial effects are evident; and while in five cases the treatment is still proceeding, because the tumours have neither disappeared nor become modified in structure, in the other five cases the neoplastic tissues have completely disappeared, or in the residual tissue repeated excisions have demonstrated the complete transition of neoplastic into sclerotic connective tissue. Of these, three presented metastases which had degenerated sooner than the primary tumour in a manner analogous to that observed in four other cases in which the glandular metastases have now disappeared, although the original tumour, or its reproduction, still exists, more or less modified.

In the five cases in which an accurate and repeated histological examination of various portions of the neoplasms has abundantly proved the benefit of the treatment, we have to deal with three cancers of the breast, with multiple metastases, one cancer of the lower end of the rectum, and one adeno-carcinoma of the thyroid. The first case treated is omitted from this group, the only one in which a preliminary excision was not made. This case was diagnosed as epithelioma of the soft palate, with cervical metastasis. As soon as the injections were begun the various manifestations disappeared, and that quickly. In waiting for the result the pieces excised, examined when the involution was well advanced, yielded the typical histological appearance, by this time found to be constant, of a change of formation now no more recognisable by the finest methods; hence the doubt as to its nature.

In all the cases the process of cure was similar; the same

[1] THE LANCET, Oct. 15th, 1910, p. 1151.

leading phases were gone through, and the same definite structure attained. The local treatment by injection into the parenchyma provoked hæmorrhagic, necrobiotic, or necrotic areas around, which were rather more numerous and more extensive than those occasioned by the remote injections, of which the main feature was cytolysis with a moderate degree of substitutive connective tissue.

Except for this difference, constant microscopic results were successively found—viz., a diffuse cytolysis of the neoplastic cells, gradually more pronounced till the morphological entity was lost, and the elements had broken up; intense infiltration, especially among the smaller cells, more marked around the vessels of various sizes; the penetration of numerous phagocytes, small and great, and of cell plasma; the active proliferation of connective and vascular tissues, invading, in fact, the whole region, some with giant cells; the transformation of the tumour substance into adult connective tissue, both fibrillary and sclerotic, with a cessation, briefly, of all reaction and production of infiltration and multiplication.

In some cases there was intense vascular stimulation of a lymphatic type; whence came a turgidity of the neoplastic tissues, and a marked increase of volume, with a change of consistency, amounting to clear fluctuation. By aspiration, in such cases, a limpid lemon-yellow liquid is obtained, having the characteristics of a transudation, containing whitish particles in suspension.

After the fluid or the infiltration had been absorbed, the substitution of tissue already affected by degeneration and by cytolysis happens as usual, which process, in its complexity, forms a picture perfectly analogous to that described by me in the case of malignant sarcomas in rats treated by homogeneous fœtal "autolysates"; it is a condition, therefore, comparable to that of sarcomas and epitheliomas engrafted on rats, previously immunised by embryonic or fœtal inoculation. From which circumstance, in short, there is a resemblance to the spontaneous evolution displayed by tumours only slightly virulent, and to the embryonic graftings in the second period of the cycle—viz., in the state of regression and disappearance.

There is no need to insist in this short notice on the importance of this uniformity of course and of results, a proof of the existence of physio-pathological phenomena, explicable by general laws, revealing themselves with the greater intensity and diffusion according to the measure and coöperation of complex factors.

One must here pause to call attention to the analogy of the structural characters, as above explained, with those noted by various authors, especially of the school of Orth, in the very rare cases of spontaneous involution of tumours in the human subject, in which may be found "zones," more or less restricted or extensive, which are affected, as I believe, by products of limited autogenetic neoplastic cytolysis, due to partial breaking down from defective nutrition or from the formation of hæmorrhagic patches. Generally speaking, one meets also in such cases with the same phenomena and the same conditions, by means of which the organism in its various changes, with only its inherent powers of cure or aided by treatment, succeeds in substituting a pathological tissue, structurally and biologically hurtful, by a common cicatricial tissue, biologically innocent.

During the treatment I have succeeded in making some remarkable observations, and have studied the anatomy, histology, and pathology of the process. In the first place, I have been able to prove that the modifications in volume are not proportionate to those of structure, so much so, that the criterion of the dimensions or of the consistency is not always a safe guide to the estimate of the therapeutic effects. In fact, in some cases there are notable differences relating specially to the original size of the neoplasm, as also to the time occupied in the cure and its methods. For example, the cases of metastasis, which even if relatively large, may not assume excessive dimensions, and are often decidedly influenced by the products of autolysis, may disappear without leaving a trace. Voluminous tumours, on the other hand, especially if treated locally, require much time for their change of substance, particularly by reason of the formation, by direct and intense action, of hæmorrhagic, necrobiotic, or necrotic patches around which the process of disintegration is long and slow, and an excess of connective tissue is formed.

A typical example of such a course was displayed by a large cancer of the breast with metastasis, in which, after a preliminary course of general treatment, a slight diminution having taken place, an excision was performed in March, 1910. The microscopic examination showed the existence of an alveolar carcinoma, with zones of neoplastic cytolysis, infiltration of leucocytes, and proliferation of connective tissue. Owing to the bulk of the neoplasm, and in order to act more directly upon it, local injections were undertaken. In May the dimensions seemed increased, on which account the previously existing metastasis, above and below the clavicle, having disappeared, an operation was decided upon. The breast having been removed and the axilla cleared out, it was found that both the main mass of the tumour and the small axillary swellings were extensively composed of abundant sclerotic connective tissue, in which here and there were found the evidence of spaces with contained cells in such a condition of cytolysis as to be unrecognisable in their minute characters, having the appearance of coloured soil, suspended *in vacuo*, only here and there outlined by fine lines like cellular membranes. Although the operation could not be considered as radical, from examination of the piece removed, and although from the extensive destruction of the parts it was not possible to suture, at the first, the whole line of incision, by continuing the injections a regular granulation and formation of epithelium was obtained without proliferation of the neoplastic elements, as proved by histological examination.

Another case also noteworthy was the adeno-carcinoma of the thyroid, which at first by general treatment disappeared, apparently by cytolysis, and a slight production of fibroplastic material, so much so that the cure was somewhat prematurely stopped, no trace being found by palpation. In the recurrence local treatment led, by the usual stages, to the subsidence of the neoplastic tissue, and to its replacement by a quantity of sclerotic connective tissue.

Another remarkable observation proves the inherent differences in the methods of cure. In fact, while normal doses, injected under the skin in the most varied parts of the body, do not produce local or general phenomena of special interest, or, at least, in some cases treated by rather strong doses, only slight redness, temporary œdema, and a momentary rise of temperature, merely a fraction of a degree, the same doses, on the other hand, provoke intense and exaggerated phenomena of the same kind when injected into the neoplastic tissues. Individuals who have had several courses of ten doses each of general injections without disturbance, when the same doses are given into the parenchyma of the neoplasm readily showed a reaction, with fever up to 39° or 40° C., with rigors and headache, followed in a few hours by a cessation of such symptoms and profuse sweating. In a few days a redness appears over the neoplasm, at times fairly extensive, with swelling and hardness. If the injections be now continued, sometimes the extent of the parts so affected increases, distension and fluctuation are felt, due to the formation of the clear lemon-coloured fluid formerly referred to, which may be at times blood-stained, as the result of aspiration, and may rapidly re-accumulate and persist. It is well in such cases to make an incision and give vent to the fluid, which goes on flowing several days, and gives place to granulation and cicatrisation of the wound, and to the substitution of the neoplastic tissues. This process is rendered difficult, at first, by the distension and infiltration obstructing the more remote superficial lymph supplies, on which the newly formed cicatrix chiefly depends. In four cases at an advanced stage of the treatment a free incision of the neoplastic parenchyma, treated by simple dressing, resulted in a good cicatrix by granulation.

The difference in the general effects of the two methods of treatment was exhibited, with a variable frequency, by all the patients, to whom they were applied indifferently. And yet, while awaiting the report of the histological examination in order to confirm the clinical diagnosis, the latter (diagnosis) is assisted and anticipated by the fact that the strongest innocuous subcutaneous dose, at once and in a marked degree, gave rise to the above group of symptoms.

To elucidate the origin of this fact I experimented on rats and guinea-pigs, injecting varied doses of neoplastic and fœtal autolysates, and of fluid taken by aspiration from effusions formed locally by the treatment. The examination of symptoms, the result of necropsies, the microscopical changes, which were common to all the substances injected, have led me to a definite conclusion.

The principal lesions of the hyperæmic and hæmorrhagic

type, subsequently degenerative, which are only obtained by doses equivalent, relatively to the weight of the body, to 400, 700, or even 900 times that usually employed in the human body, are found in the excretory organs, the liver and kidneys, and in the internal protective secretory organs, as the pituitary and thyroid glands, and the suprarenal capsules, these last organs, indeed, being those most frequently and most seriously attacked by hæmorrhages. Such an anatomical and pathological condition, both naked-eye and microscopic, has been detected also, in the case of doses incapable of causing it in healthy guinea-pigs, in four which were accidentally found to be tuberculous at the necropsy, while the others of the same group showed no special alteration.

I have, therefore, come to regard the transitory group of symptoms as a slight, but complex, toxic phenomenon, favoured at first, in the case of local injections, by peculiar structural conditions, especially as regards the vascularity of the surrounding parts and the friability of the blood-vessels, leading to a more abundant and more rapid absorption by the blood; and, in the second place, increased by the excessive action due to the contemporaneous penetration of the products of cytolysis of the neoplasm, if such have already been formed. Such an explanation is confirmed by the fact that, on the disappearance of the neoplastic tissue, the effects of the local injections in no way differ from those of the general treatment.

The mechanism of the action of the autolysates requires diligent study before it can be defined with certainty and accuracy.

On a hypothesis based on somewhat similar work I have endeavoured to prove that, if we have to deal with an enzymatic process, it is most decidedly due to the combined action of all the enzymatic powers of the fœtal organism. I have, therefore, made numerous tests on films of the serum of coagulated blood, which were easily dissolved by even weak solutions of trypsin. The autolytic products from five sections of tumours of rats and from seven neoplasms from the human subject have afforded me on two occasions, and only one quite distinctly, zones of digestion. But out of 11 fœtal autolysates tested, differing as to the age of the fœtus and as to the stage of the experiment, none has dissolved the albumin subjected to the test. In the same way the fluid aspirated from the fluctuating parts produced by local treatment has given a negative result in two cases and a positive result in one, which was not trustworthy by reason of contamination of the material.

These tests on coagulated albumin and on extra-corporeal tissues are not proofs of the enzymatic property of fœtal autolysates. More numerous and more delicate researches are certainly necessary for such conclusions. It seems to me, however, fair to form some conclusion on the direct and elective actions of these autolysates.

The direct action in the living subject between the products of fœtal autolysis and neoplastic cells is proved by the following considerations:—

(*a*) The failure to immunise rats against the inoculation of homogeneous sarcoma, after preventive treatment, even much prolonged; their receptivity was not modified by the progressively increased injections of autolysates.

(*b*) There was no effect on the pulp of sarcoma produced by the serum of rats prepared with injections of homogeneous fœtal autolysates; the pulp thus employed acted like fresh pulp.

(*c*) The transitory resistance acquired by rats against tumours by preliminary inoculations of embryonic or fœtal tissues; this immunity ceases after a short time.

(*d*) The fact that if the treatment be suspended when no lumps are to be felt exceptionally a case may again develop the neoplasm from the residual elements, which are not apparently under the influence of hurtful substances produced by the organism for some time after the treatment.

(*e*) The readiness with which the changes in the parenchyma of the neoplasm are produced by local injections before the formation of antitoxins is possible.

(*f*) The persistence of the therapeutic action with local and general reaction, after even a fairly long period of treatment and numerous injections; there is, therefore, no evidence of immunisation.

The elective action is proved by the effects obtained by general injections in rats and in the human subject—e.g., in the case of a cancer of the rectum and in the early treatment of the adeno-carcinoma of the thyroid, as also in six out of seven cases of relapsing metastasis—by the fact that in the normal tissues there is no evident reaction; in fact, only during a few days a slight hyperæmia is met with at the point of injection, and sometimes a small zone adherent to the subcutaneous tissue which shows under the microscope a very fine structure with a fibrinous network and a few scattered leucocytes, whereas, in contrast to this condition, in the tissues under treatment the changes already described are found; by the clearly marked lesions which, soon after the injection into the substance of the neoplasm, appear along the line of puncture, such as are not found in normal tissues.

This double proof of the direct and elective action of the autolysates on the effect of the treatment points to the relation between the dose of the substance injected and the volume of the tumour. In practice it happens that, as we must not exceed certain fixed doses, if the tumours be unusually large the autolysates injected at a distance destroy a less amount of the neoplastic tissues than that formed in the same period of time. It is, accordingly, only possible to obtain a delay in the morbid process, which will become less and less important the more the disproportion will increase between the continued employment of the maximum dose adopted and the progressive increase of the volume of the tumour. In such cases one must have recourse to the most energetic local treatment, taking care in the case of marked œdema or evident effusions to aspirate, or in other ways to get rid of the products of neoplastic cytolysis.

Moreover, in such conditions of volume and rapid growth of the neoplasm, and of action of the autolysate both limited and proportionate to its dose, it increases the chance of success in destroying the neoplasm and in restoring the patient's health to excise or destroy freely in order to act on any possible residual cells, and on the metastasis, only by general treatment. Individuals with inoperable tumours can thus undergo the treatment without the risks due to the absorption of toxic products, especially such as are of neoplastic origin, and will exhibit, as early signs of improvement, marked modifications of their general condition, and especially of the blood.

This varied effect of one and the same treatment has suggested the hypothesis brought forward by Bagnami at a recent meeting of the Academy of Medicine of Rome, of the complexity of the substances contained in fœtal autolysates. Of such one group may have a stimulating action on the healthy tissues, and especially on the hæmopoietic organs; and another group may be responsible for the cytolytic action on the neoplastic tissues. One may also admit the existence of a single series of active principles, which would act successfuly, in different ways, according to whether they had to deal with normal cellular elements or neoplastic elements; hence a double favourable result.

The same mechanism of elective cytolytic action, without which the tumour would not otherwise disappear, forms a contra-indication to the treatment in cases with cachexia, in which, by all means, if a cure be undertaken, we must try to prevent the increase of intoxication. The toxic action inherent to the constitution and biology of malignant tumours discourages the use of their autolysates in experimental therapeutics, because there would result an excessive action, more intense and more serious than with other methods. It is necessary, in fact, to employ homogeneous embryonic or fœtal autolysates. In my cases I have employed embryos and fœtuses of from two to six months of intra-uterine life, adopting the products of *fœtal* autolysis more frequently and for a longer period.

It cannot be denied that autolysates from adult organisms may possess a similar action, although it must be reckoned less efficacious, to judge from the less potency and the less frequency with which they confer an immunity against tumours as appears from numerous experiments. It seems to be rather more difficult to admit the same beneficial power in the case of heterogeneous autolysates, especially as on the basis of modern researches on tumours the laws of biological selection appear to be distinctly confirmed under the most varied aspects.

The homogeneous fœtal autolysates are prepared by ordinary methods, observing the strictest rules of asepsis. The fragments, or the pabulum, of the fœtus are placed in a physiological solution, of an average strength of 1 grm. to 20 cgrm., a suitable quantity of thymol or phenic acid being

added, and covered by a layer of sterilised oil or toluol. The mixture remains in the incubator at 37° C. for about two months, and prior to use its sterility is tested.

The injections vary in dose from 2 to 3 c.c. twice to four times a week, according to the patient's age, condition, individual tolerance, the bulk of the tumour, the seat of the injection, and the specific gravity of the autolysates, which latter ought to be, at the moment of their employment, a homogeneous emulsion, and not a clear superjacent mixture. The treatment extends to a variable number of months, according to the local and general conditions.

While in this article I limit myself to describe the action of autolysates on malignant tumours in the human subject, and to make a general statement as to their therapeutic effect, I have at the same time arrived at conclusions of some statistical value, which prove the exactitude of all I have stated, but do not admit the conception of a statistical comparison. Such could only be made after a study of numerous cases, and only when time, rather than repeated excisions and numerous histological controls, shall have proved that even the last neoplastic cells have been destroyed, and consequently all danger of recurrence eliminated. All the more the fact remains that, without proof of an immunisation, there remains in every individual the possibility of the development of blastomic cells, on which account, if all the conditions requisite for the formation of a neoplasm be again present, the subject in question is always liable to, and helpless against, such a contingency.

The observations, however, made on both men and animals have so far proved that, if the treatment be persisted in for some time after its evolution and disappearance, the tumour does not recur. And if, as an exception, a case in the human subject relapse on account of a premature suspension of the injections, if the latter be resumed their effects are again manifest. Time only will permit of the collective study of cases submitted to this treatment in more favourable conditions than were hitherto possible, when one may be able to supervise and study the process in every detail, with fresh material, and, by this original method, deal with inoperable cases of voluminous tumours and their metastases.

Finally, I desire to add that I have indicated the method and its results in detail, because, as may be readily understood, in relating the clinical researches, which are indispensable for a fair conclusion, one has to bear in mind the relative number of cases treated and the long time of trial necessary for a satisfactory judgment.

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

THE RESULTS OF OPERATION IN A CASE OF HAMMER NOSE.

BY F. B. JEFFERISS, F.R.C.S. EDIN., M.R.C.S. ENG., L.R.C.P. LOND.

As the effects of operative interference in cases of rhinophyma, or hammer nose, are not often seen the accompanying photographs of a case of this kind may be of interest. This distressing condition first appeared when the patient was

FIG. 1.

26 years of age, and grew steadily worse, making his life a misery and his nose a constant source of annoyance to himself on account of the attention and ridicule it evoked.

The patient at the time of operation was 64 years of age. He was, and had always been, temperate. With

FIG. 2.

the exception of a faint aortic bruit he was a healthy man and had had no serious illness. Under chloroform anæsthesia the whole of the superfluous tissue was removed

in one piece by two lateral incisions in a wedge-shape, leaving a V-shaped shallow cavity with the incision extending down to the cartilage. The "flaps" were then trimmed somewhat and brought together by three or four catgut stitches. There was considerable hæmorrhage, necessitating ligature of several small vessels. The wound healed rapidly, and the result is in every way satisfactory, little scar remaining.

The marked improvement in the man's features and general bearing is shown in the photograph, and the satisfaction derived by him from the fact that his personal appearance is no longer a subject of notice or comment is an ample reward for undergoing so simple an operation.

Chatham.

NOTES ON A CASE OF OPERATION FOR RUPTURED MENINGO-ENCEPHALOCELE.

BY WILLIAM EDMOND, F.R.C.S. ENG.,
RESIDENT MEDICAL OFFICER, LONDON TEMPERANCE HOSPITAL.

IT is not often that one is suddenly called upon to deal with a case of meningo-encephalocele, so that the publication of the following case may be of interest to the profession, particularly as regards the severity of the operation and the somewhat unexpected recovery of the patient.

A newly born infant was brought to the London Temperance Hospital by the midwife in attendance at the labour on account of a large swelling at the back of the head. It appeared that the labour had been protracted and difficult owing to a mass which presented at the side of the head. Whilst the head was being delivered the swelling burst, which alarmed her so much that she wrapped the baby in a blanket and hurried with it to the hospital.

The child, who weighed 7 lb., appeared healthy, was of a good colour, and cried lustily when handled. The pulse-rate was 145. Over the posterior fontanelle was a large swelling. The skin covering it was thin and flaccid and showed a few dark hairs. At the most prominent part the skin had evidently been subjected to prolonged pressure; it was dark red, almost black in places, and had given way, so that there was a ragged tear 2½ inches long from which blood-stained cerebro-spinal fluid was dripping and portions of brain material protruding. When the child cried there was a marked impulse. There did not appear to be any hydrocephalus associated with the condition. It was clearly a case that called for some radical measure if the child's life was to be prolonged. The sloughing condition of the coverings of the hernia precluded the possibility of repairing the rent by suture, nor was there any pedicle which might have been tied. An attempt at partial reduction by sponge pressure sent the child into convulsions. Under the circumstances I decided to operate.

The child was first quieted by a few drops of chloroform. The head was prepared as carefully as possible and covered with sterile gauze. An attempt was made to apply a cranial tourniquet, but owing to the shape and the yielding nature of the head this was unsuccessful. Under a stream of warm normal saline solution two flaps of healthy skin were cut—one from the upper, and one from the under surface of the hernia. The underlying dura mater was found to be very adherent, and had to be dissected off the skin flaps. Two lateral flaps of dura were then formed, during which the superior longitudinal sinus had to be sutured. The contents of the sac appeared to be loose, spongy connective tissue, but at the base there was a considerable protrusion of brain substance on either side of the exposed falx cerebri. It was found necessary to remove this portion of the brain, and after the vessels had been tied the dura was brought together, the edges overlapped and sutured to each other, and to the falx cerebri. This secured an almost watertight union. The skin flaps were then united by a continuous silk suture and a firm pad was applied. When sutured the incision, which was transverse, measured 2 inches. The child was convulsed during the removal of the brain substance and the opposing of the flaps of dura.

For the first 24 hours there was some leakage of cerebro-spinal fluid—in all, about one ounce—through the right extremity of the incision. This point was touched with the cautery, and from that time the wound kept dry. The sutures were removed on the ninth day. There was no motor paralysis, nor, as far as I could determine, any visual defect, which is surprising in view of the fact that the portions of lacerated brain removed must have come from the neighbourhood of the occipital poles. The child was discharged from hospital at the end of the third week.

NOTES OF A CASE OF STRANGULATED *LEFT* INGUINAL HERNIA WHOSE SAC CONTAINED THE APPENDIX VERMIFORMIS (INFLAMED), THE CÆCUM, AND THE ILEO-CÆCAL VALVE.

BY DOUGLAS GORDON CHEYNE, M.B., CH.B. ABERD.,
RESIDENT MEDICAL OFFICER, ROYAL WATERLOO HOSPITAL FOR CHILDREN AND WOMEN.

THE condition presented in the following case is, I think, so unusual as to justify publication.

The patient, a male child aged 2 years, was admitted to the Royal Waterloo Hospital on May 7th, 1911, at 7 P.M. The history obtained from the mother was as follows. The patient had had a rupture on the left side since soon after birth. For five days previous to admission the child had had a cough. During this time the rupture had gradually increased in size, and for two days it had been irreducible, a complication which had not occurred before. Since the rupture had become irreducible the bowels had been absolutely constipated. The child had vomited once shortly before admission.

On admission the child was seen to be well nourished. Temperature, 99·8° F.; pulse, 140; respirations, 25. There was evidence of bronchitis on auscultation. The legs were held in the position of flexion, with the abdomen rigid. The left half of the scrotum was occupied by an oval swelling of the size of a turkey's egg. It was tender on palpation, dull on percussion, and absolutely irreducible even after a hot bath and an enema.

Mr. Ivor Back, whom I have to thank for allowing me to publish this case, operated at 10 P.M. An incision was made over the swelling; the sac was exposed and opened. Two to three ounces of yellow fluid escaped. Intestine then came into view; this consisted of the cæcum, the appendix, and 2 or 3 inches of ileum. The constriction, which was at the internal ring, was divided. Strangulation was just beginning, the gut being congested and purplish in colour at the point of constriction. The appendix was large and reddened. It was removed in the ordinary manner. The pathological report was: "Acute diffuse inflammation." The intestine was then returned to the abdomen, and an ordinary radical cure (Bassini) was performed. Convalescence was uneventful.

The unusual interest of the case lies in the fact that not only was the appendix in the sac of a *left* inguinal hernia, but that it was also definitely inflamed. I should add that I have examined the child and can find no evidence of any inversion of the viscera.

ROYAL SOCIETY OF MEDICINE.

MEDICAL SECTION.

Slight Strokes.

A MEETING of this section was held on Oct. 24th, Dr. FREDERICK TAYLOR, the President, being in the chair.

Dr. S. T. PRUEN read a paper on Slight Strokes. He said that some years ago, having been called to see an old lady, who mentioned amongst other matters that she had been worried with a feeling of pins and needles which had occurred simultaneously in the right arm and leg, which feeling had come on quite suddenly and had passed off, though not completely, in the course of a few hours, he had been driven to the conclusion that the cause must have been cerebral in origin and might have been a stroke. Within a month this old lady had a stroke affecting the right leg, and within a year an attack of right hemiplegia which caused her death a few days later. This case caused Dr. Pruen to watch all his elderly patients and to inquire into the antecedents of all those who had obvious strokes; with the result that it was found that

many of them could give histories of previous slight attacks of most varied kinds. In this way Dr. Pruen collected 18 or 20 symptoms or groups of symptoms. In his opinion, more than three-fourths of the classical strokes have these symptoms as a prelude once or twice repeated. Dr. Pruen quoted the description of a first stroke from Dr. Samuel Gee's "Clinical Aphorisms," which says: "The first thing you observe is that his speech is indistinct in consequence of defective articulation. He complains of a feeling of numbness in the right arm and leg, especially in the hand; and, on further examination, you discover that he is suffering from a slight hemiplegia on the right side, affecting arm, leg, and face." Dr. Pruen said that his own observations led him to believe that this stroke was probably not the first from which the particular patient suffered, but that it was more likely to have been the second and might have been the third. In describing the symptoms which in his opinion constitute slight strokes Dr. Pruen premised that the patient is over 50 years old; the attack is a unique experience as far as the patient is aware; the attack comes on with absolute suddenness; and that the symptoms disappear very slowly but with a steady progress. The symptoms he had observed were: (1) Pins and needles in the arm and leg simultaneously; (2) stumbling with obviously no cause; (3) giddiness; (4) nausea; (5) palpitation; (6) faintness; (7) sudden weakness; (8) confusion of ideas; (9) change of character; (10) headache; (11) sleepiness; (12) feeling of deadness in the abdomen; (13) paresis of one vocal cord; (14) wasting; (15) dysphagia; (16) odd feeling. Frequently there was a combination of one or more of these symptoms, but in almost every case one symptom predominated. Dr. Pruen had been much struck with the large part the vagus (and presumably the sympathetic) plays in the condition of a patient who has had a stroke. He considered that degeneration of the vascular system and some local increase of tension were the probable accompaniments, if not the determining causes, of slight strokes; and he thought that the vascular changes were of a more insidious nature than those usually associated with strokes. The causes which above all others seemed to produce them were mental ones, either sudden shock or prolonged worry. Dr. Pruen, summing up his paper, said that slight strokes almost always preceded ordinary ones, that slight strokes were always followed by ordinary ones, that the nervous implication in strokes was always more widespread than was generally recognised, that the predisposing causes of strokes were not the gross lesions generally associated with them, and that molecular, rather than molar, movement was the determining factor.

Dr. J. W. CARR said that the practical outcome of the paper was the help it afforded not only in recognising the symptoms of slight strokes and the dangers which they implied but also in taking precautions to ward off any future attacks. He commented on the difficulties in diagnosing cerebral hæmorrhage and thrombosis.

Dr. F. PARKES WEBER, alluding to the dilatation of the bladder and constipation referred to by Dr. Pruen as due to some dulling of sensibility, suggested that in some cases in elderly persons it was due rather to dulling of muscular sensibility than to dulling of the sensitiveness of mucous membrane.

Dr. MICHAEL G. FOSTER described instances in which transient aphasia with partial paresis had occurred in parturient women.

Dr. ROBERT HUTCHISON declared that the paper was valuable because it was based on the experience in general practice by a man who saw a great number of elderly patients, and the members of the section would like to hear more papers of the kind. He referred to the transient hemiplegia which may take place in the course of migraine.

After Dr. PRUEN had replied the meeting came to an end.

PATHOLOGICAL SECTION.

President's Opening Remarks.—Experimental Production of Appendicitis by Intravenous Inoculation of a Diplococcus.—Sarcoma-producing Mouse Carcinoma.—Muci-carmine Staining Method.—Carcinoma of the Uterus in a Rabbit.

A MEETING of this section was held on Oct. 17th, Dr. R. T. HEWLETT, the President, being in the chair.

The PRESIDENT, in the course of his Opening Remarks, said that on looking back over the progress of pathology during the last 20 years he was more and more struck with the wide range of knowledge required if the pathologist was to follow, even in outline, the output of pathological work. Reference was made to the importance of chemical and physical applications in biology and pathology. As regarded physical factors, he referred to Professor D'Arcy Thompson's address at the British Association on the influence of physical forces in moulding the form of living organisms. The similarity of organic forms and those which physical forces were competent to produce had revived the idea of the possibility of spontaneous generation, and the work of Burke, Leduc, and others suggested that this problem, which had been worked at persistently by Bastian for so many years, could not be dismissed so contemptuously as formerly, and was worthy of critical work in order to elucidate it. Reference was made to the value and limitations of biometrical methods in experimental work, and, finally, the President pointed out the advantage which the society offered to those who contributed papers—viz., speedy publication.

Dr. F. J. POYNTON and Dr. ALEXANDER PAINE read a paper entitled "A Further Contribution to the Study of Rheumatism, the Experimental Production of Appendicitis by the Intravenous Inoculation of the Diplococcus," which is published in full in this issue of THE LANCET, p. 1189.

Mr. S. G. SHATTOCK and Dr. L. S. DUDGEON communicated the result of an experiment made with a Sarcoma-producing Mouse Carcinoma. The observations of Ehrlich and Apolant, that certain mouse carcinomata on being grafted into a further series of mice were replaced by sarcomatous formations, had been amply confirmed by Dr. B. R G. Russell. The theoretical difficulty of explaining such a result on the assumption that the epithelial cells of the grafted carcinoma furnish the cells of the sarcoma was so insuperable that the only way of evading it would be to regard the grafted tumour as an endothelioma in place of a proper carcinoma. The transformation of epithelial cells into connective tissue was a phenomenon unknown, at least after the conclusion of embryonic development, whereas the same transformation of endothelium, seeing that the latter tissue was of mesoblastic source, did not present the same difficulty; the fibroblasts produced in the organisation of an intravascular thrombus were derived from the proliferated endothelium of the vessel. The apparent transformation, however, offered no histological anomaly, for the simple reason that the process was one not of transformation but of substitution; the sarcomatous growth arose from the connective tissue of the host. The experiment of the authors consisted in the repeated subcutaneous insertion of the particular tumour worked at by Dr. Russell, but after the cells had been rapidly killed by drying the pulp in the layers at 37° C. In the group of cases, six mice received four subcutaneous injections of the dried material after it had been re-made into a pulp by moistening it with salt solution. The injections were made weekly in the same region. No growth of any kind ensued. The experiments showed that for the incitement of the sarcomatous growth in the host, the action of the living carcinoma cells was necessary, and that the access to the circumjacent tissue of the materials extractable from the dead cells was not sufficient.

Mr. P. P. COLE gave a demonstration illustrating the use and value of Muci-carmine as a Staining Reagent. He showed that the results obtained with this stain were constant and accurate, provided the stain was made properly. He described the method of making the stain and advocated as a fixative a saturated solution of perchloride of mercury with the addition of 5 per cent. of glacial acetic acid. He referred to the adoption of this stain by Mr. W. Sampson Handley in the investigation of cancer of the large bowel, and indicated that the merest traces of mucus were picked out with the utmost accuracy, leaving other tissues unstained.

Dr. A. LEITCH read a paper on Carcinoma of the Uterus in a Rabbit.

OPHTHALMOLOGICAL SOCIETY.

Presidential Address.—Hereditary Cataract.—Hereditary Night-blindness.—Exhibition of Cases and Specimen.

A MEETING of this society was held on Oct. 19th, Mr. J. BOWRING LAWFORD, the President, being in the chair.

After the formal presentation of vol. xxxi. of the Transactions the PRESIDENT delivered his Introductory Address.

Having referred to his election as President in a few graceful and grateful phrases Mr. Lawford proceeded to deal, in considerable detail, with the subject of vaccine therapy, passing in review the work of many continental and British investigators, and then went on to refer to their bearing on the treatment of eye diseases. He concluded by a reference to immunity, active and passive, and to the prospect of success in eye diseases. Sympathetically appreciative allusion was made by the President to the decease of Dr. Hughlings Jackson, one of the original members of the society, and to the fact that he was one of the earliest physicians to insist on the importance of ophthalmoscopic examination in diseases of the nervous system.

Mr. E. NETTLESHIP communicated, for Dr. J. S. Manson of Warrington, a paper entitled "A Case of Hereditary Cataract." It was a case of hereditary lamellar cataract occurring in four consecutive generations, affecting 13 persons (6 males and 7 females), and transmitted in all cases by females who were themselves affected. Three members of the pedigree, in three different generations, had a congenital deformity of the little fingers, which appeared to have been independent of the cataract, for only one individual showed both the digital and lenticular abnormality.

Mr. NETTLESHIP also contributed a paper entitled, "A New Case of Hereditary Night-blindness." It was the form without opthalmoscopic changes, in which the abnormality was associated with myopia, and descended, as in colour-blindness and several other conditions, through females themselves normal. Twenty cases had been discovered in this extensive genealogy. Photometric records and field measurements of several were recorded; in one there was a partial ring scotoma. Several members of the pedigree were myopic without being night-blind, and several (some of them night-blind, others with normal sight) were mentally affected. There was only one consanguineous marriage in the entire pedigree.

The following cases and specimen were shown:—

Mr. GEORGE COATS: Two cases showing a Small Superficial Opaque Ring in the Cornea. Mr. Coats thought that if it was not a deposit it must be a congenital opacity. He had seen another case of the same kind.

Mr. N. BISHOP HARMAN demonstrated a new Photometer for school doctors, a portable and simple instrument whereby an exact knowledge of the amount of light existing in schools, without relying on the uncertainties of personal estimates, could be obtained in candle-power—that of the ordinary London sperm candle.

Lieutenant-Colonel L. J. PISANI, I.M.S.: A case of Cyst of the Iris.

Major W. T. MOULD, R.A.M.C.: A case of Vaccine Pustule in the Eyelid.

Mr. R. A. GREEVES: A case of Tumour of the Ciliary Body in which there was recurrence after removal. Neither caustics nor the application of CO_2 checked its growth.

Dr. D. G. GREENFIELD: A case of Unilateral Optic Neuritis in a case of Disseminated Sclerosis.

DEVON AND EXETER MEDICO-CHIRURGICAL SOCIETY.

Eclampsia.

A MEETING of this society was held on Oct. 13th, Mr. J. M. ACKLAND, the President, being in the chair.

Dr. G. P. D. HAWKER showed a case of Extensive Osteoma of the Tibia in a middle-aged woman. He then read a paper, illustrated by a case recently under his care, to open a discussion on Eclampsia. The patient was a primipara, aged 25 years, whose family history showed an unstable nervous equilibrium, the woman herself being distinctly of the nervous type. There was a history of scanty urine, with a heavy deposit of "sand." During the later months her legs had swelled. In the course of the last few weeks she had had what the neighbours called hysterical fits, in which there was no history of loss of consciousness or of biting of the tongue. She had cried out freely during the attacks and had never fallen. When summoned at 11.30 A.M. on Jan. 27th Dr. Hawker found labour pains, which had been established for 12 hours, now vigorous and recurring every five minutes. The os was the size of half a crown and the presentation and pains appeared to be normal. The general condition was satisfactory. A little urine had been passed at 9 A.M. Fifteen grains of chloral were given. At 3 P.M. Dr. Hawker found the os fully dilated and the pains strong; ten minutes later there was a general convulsive fit lasting three minutes. Chloroform was at once administered and a catheter passed, bloody urine being drawn off. A colleague was sent for and instrumental delivery carried out. Immediately the forceps was applied a fit occurred, followed by two others at rapid intervals. With the third fit delivery was effected, but with considerable laceration of the perineum. The placenta gave little trouble, but two or three smaller fits occurred during the repair of the perineum. One drachm of bromide was given by the rectum. At 7.30 P.M. she had had seven fits in all and was unconscious, with widely dilated pupils and arched back. Slight fits continued up to 10 P.M., when the bromide was repeated. At 11.30 P.M. the pulse was 124 and the temperature 103° F. During the night 11 fits occurred in spite of bromide every three hours and a hot pack. On the 28th a pint of urine was drawn off by catheter and found to be of specific gravity 1020 and to contain one-third albumin. The fits now lessened both in frequency and violence, but she was still unconscious. The knee-jerks were exaggerated and Babinski's sign was present. On the 29th there had been no fits since 9 P.M. the previous night, and albumin had fallen to one-tenth. Blood cells and casts were present. On the 30th she was semi-conscious; she had passed urine. The discs, examined on this day, were found to be blurred, but no hæmorrhages were noted. The plantar reflex was now flexor. On the 31st there was incontinence of urine and fæces. Bromides were stopped. Further progress was gradual, but in the main satisfactory. She was quite rational on Feb. 3rd, and there was no incontinence. The temperature, never high save on the day of delivery, now reached the normal. The urine still contained a trace of albumin, but no casts were noted. On March 10th she was convalescent and allowed to get up. The urine was found free of albumin and no casts were noted. Dr. Hawker emphasised the fact that this patient had had symptoms for two months before delivery, but as there had been concomitant indigestion she had subsisted mainly on a milk diet, and thus unconsciously had adopted the right diet for her condition. The fits which occurred prior to labour appeared to have been really hysterical. The actual eclamptic convulsions did not occur until labour was well advanced, and were well controlled by chloroform. He attributed recovery in this case to the good nursing, the constant alteration of position, thereby avoiding pulmonary œdema, and to the diminution of toxins by copious saline enemata and frequent hot packs. A notable point was the absence of albumin or casts in the urine at the end of six months. Dr. Hawker felt somewhat at a loss for an explanation of the presence of Babinski's sign on the second day. His hospital experience had not impressed him with the value of morphine in the treatment, more especially in relation to pulmonary complications—œdema of the lung being the rule where this drug had been employed. The number of fits seemed to have no bearing on prognosis, but he considered that the inception of convulsions after labour was a bad sign. Dr. Hawker referred briefly to the pathology of eclampsia and mentioned Albec's and Lotze's injection experiments with liquor amnii.[1] Animals so injected showed the same changes in the liver as patients dying from the disorder. Normal liquor used as a control was innocuous. Disintegration of the placenta would be the primary cause. As regards treatment, a recent meeting of the Obstetrical Section of the Royal Society of Medicine seemed to be in favour of emptying the uterus. Out of 36 cases reported by Dr. W. Alexander,[2] of Liverpool Workhouse Hospital 7 cases were hastened, with 2 deaths, a mortality of 28·5 per cent.; whereas 29 were delivered naturally, with a mortality of 9—i.e., 31 per cent. Dr. Alexander's treatment consisted of saline purgatives, diuretics, and saline injections, together with nerve sedatives such as bromide, chloral, and morphia. He also cited Dr. Hastings Tweedy's report of 30 cases of eclampsia at the Rotunda Hospital.[3]

Dr. A. W. F. SAYRES mentioned a severe case he had recently met with in his own practice. Dilatation, version, and instrumental delivery were performed, but the subsequent condition became one of deepening coma. Dr. Sayres

[3] THE LANCET, Feb. 4th, 1911, p. 306.

attributed the eventual recovery to the agency of hot packs. The woman became maniacal during the first week, but at the end of one month convalescence was well established.

Dr. C. J. VLIELAND reported two cases, in one of which he had performed version and accelerated delivery. Severe fits followed, but when the patient was almost *in extremis* recovery followed promptly on venesection. The urine subsequently cleared of albumin. In the second case delivery was not hurried, and the woman did well. His experience of these cases gained from 30 years of private practice was against violent emptying of the uterus.

Dr. HENRY DAVY did not think that the placental theory was proved. In his experience post-partum cases were the most serious; the majority he had seen had proved fatal. He always dreaded a case of eclampsia in which the convulsions did not appear until after labour had been completed. He spoke only as a physician.

Dr. R. V. SOLLY spoke in support of the placental theory in the pathology of the disease. Taking into account the post-mortem changes in the liver and kidneys, chloroform was not justifiable in the treatment. Bleeding and subsequent substitution by saline solution were more practical. He had seen Dr. Hawker's case with him, and testified to the value of the packs.

Mr. RUSSELL COOMBE commented on the weakness of the soda solution (30 grains to the pint) advocated by Dr. Tweedy.

Dr. SHIRLEY STEELE PERKINS quoted two of his own cases in one of which the convulsions arose post partum and death occurred in six hours, no treatment having the slightest influence. In the second case, convulsions were established when the cervix admitted but two fingers. He dilated and delivered. Recovery was complete. These cases supported the relation of onset of fits to prognosis enunciated by Dr. Davy and Dr. Hawker. As regards treatment, Dr. Perkins advocated delivery, and subsequent pilocarpine subcutaneous injections, with hot packs.

Mr. C. E. BELL mentioned a severe case of eclampsia where chloroform inhalations were long maintained without disastrous after-effects. His own experience of chloroform was favourable and he had recently seen a case in which recovery followed salines alone. His experience of post-partum eclampsia was a most melancholy one.

Mr. G. L. THORNTON recollected a case some 14 years ago where convulsions and albuminuria came on at the sixth month in a previously healthy multipara. The fits recurred at short intervals, and chloroform was required for the passage of a catheter. Coma being imminent the emptying of the uterus was discussed, but on the advice of a practitioner of some 50 years' experience bromide and chloral were given, with the result that the fits gradually ceased and albuminuria diminished. The woman was subsequently delivered of twins at full term and made a good recovery. There was no recurrence of the eclampsia, but some albuminuria remained. Mr. Thornton also briefly referred to a recent case of a multipara who had enjoyed good health prior to a molar pregnancy. When summoned to her he found general anasarca, œdema of the lungs, and a high degree of albuminuria, with numerous casts. After delivery albuminuria and anasarca rapidly disappeared. There were no convulsions, but the patient was at times extremely drowsy. This case, though perhaps not quite comparable with those previously cited, supported the intra-uterine auto-intoxication theory with regard to the production of the nephritis.

Dr. HAWKER replied.

OXFORD MEDICAL SOCIETY.—The first meeting of the session of this society was held in the Radcliffe Infirmary on Oct. 13th, Mr. R. H. A. Whitelocke, the President, being in the chair.—Dr. H. G. Frean related the history of an Indian, aged 20, of a quiet studious temperament, who was found at 6.30 one morning in bed deeply unconscious. The breathing was deep and stertorous and the dejecta had been passed into the bed. The pulse was full, 84 per minute. The limbs were flaccid; there was only a slight corneal reflex. The pupils were moderate in size and the temperature was raised. There was a gradual but slow return of consciousness within the next 48 hours. The patient remembered nothing of the previous two days. The evening before the attack he had dined quietly with his tutor. There was no history of any excess and no previous history of epilepsy.—Mr. P. E. H. Adams gave the history of a case of Double Proptosis in a male aged 50. This began suddenly with an irritation in the right eye, which became puffy and later definitely proptosed, and the vision deficient. No inflammatory trouble could be detected by puncture of the orbital tissues on two occasions. Proptosis and chemosis followed in the left eye. The temperature rose, and the patient died in 48 hours from the beginning of the symptoms. At the necropsy the right sphenoidal sinus was inflamed and contained muco-pus. The inflammation had spread to the right cavernous sinus, from which it had tracked over to the left, and there was early acute meningitis.—Dr. E. Mallam showed a case of Crossed Paralysis in a woman aged 56. The history began in 1906, when the eyesight became impaired. At the present time she had a nuclear or nerve lesion of the third, fourth, and sixth nerves of the left side. On the right side there was a supra-nuclear lesion of the seventh nerve, hemiplegia of the right side of the body, and blindness in the right field of vision, the left halves of both retinæ being insensitive. There were no signs of intracranial pressure and there had only been occasional, though at times severe, headache. The condition was thought to be one of gummatous meningitis, and the patient was improving on potassium iodide.—Mr. E. W. M. Higgs described a case of a woman, aged 23, in whom Eclampsia began at full time. Chloroform was given, the membranes were ruptured, and internal version was performed. The child was born without difficulty. In removing a slightly delayed placenta it was found that the uterus had been torn from the vagina and the omentum was projecting through. The patient was in such a critical condition that it was deemed advisable to do nothing but give an ordinary vaginal douche. The unconsciousness, with occasional convulsions, persisted for four days, and the temperature was raised. In the fourth week the patient was normal except for white leg. In the seventh week the patient was able to get up, and since that time she has been in very good health.

THE NEW LONDON DERMATOLOGICAL SOCIETY.—A meeting of this society was held on Oct. 12th, Dr. Phineas S. Abraham, the President, being in the chair.—Dr. W. Knowsley Sibley showed: (1) A woman with Leucoderma, treated by hyperæmia and by cataphoresis with corrosive sublimate solution; (2) a young woman with Bazin's Disease, associated with Scrofulodermia, in whom the von Pirquet reaction was positive; (3) a man with Popliteal Eczema of 14 years' duration, cured by X rays; (4) a man, aged 56, with Chronic Urticaria associated with Pyorrhœa Alveolaris, who had been treated successfully by a vaccine, with the result that the insomnia, as well as the eruption, had now disappeared; (5) a woman, exhibited at a previous meeting of the society, with Dermatitis Herpetiformis, to show the improvement that had taken place as a result of the administration of a vaccine; and (6) a man with severe Tinea Sycosis.—Dr. G. Norman Meachen showed: (1) A child with Urticaria Pigmentosa; (2) a boy, aged 8, with Parapsoriasis of Brocq; and (3) a boy, aged 11, with Late Hæmorrhage occurring in the Telangiectases after X ray treatment for enlarged tuberculous glands in the neck; no exposures had been given for two years.—Dr. Harry Samuel showed a man with a Roseolar as well as a Maculo-Papular Secondary Syphilitic Eruption.

PRESENTATIONS TO MEDICAL PRACTITIONERS.—Mr. Norman Porritt, L.R.C.P. Lond., M.R.C.S. Eng., was presented at the annual dinner of the Huddersfield Medical Society on Oct. 18th with two pairs of silver candlesticks. In making the presentation Dr. J. Irving said that Mr. Porritt, who was retiring from practice, would carry with him the affectionate regard of all his patients and the good will and esteem of every member of the medical profession who had been brought into contact with him. The presentation included two silver vases for Mrs. Porritt.—At the annual meeting of the Bristol Centre of the St. John Ambulance Association, held recently, Mr. Cyril Claude Lavington, M.B., B.S. Durh., was presented with a vellum vote of thanks conferred by his Royal Highness the Grand Prior and the Chapter-General of the Order of St. John of Jerusalem, in recognition of his special services in connexion with ambulance work in Bristol.

Reviews and Notices of Books.

A Traveller's Study of Health and Empire. By FRANCIS FREMANTLE, County Medical Officer of Health. London: John Ouseley, Limited. 1911. Pp. 369. Price 7*s.* 6*d.* net.

THE author of this volume has had within the last few years the opportunity of extended travel undertaken with the object of studying the problems of public health in relation to various peoples and races and systems of government. His aim is to persuade the public of the significance of these problems, and to secure a due attention to their solution in the future administration of the British Empire. In a series of papers he presents the results of his experiences in an attractive form, designed, as he says, for the general, rather than the professional, reader.

The first chapter is a graphic account of anti-plague measures in India—as carried out by Mr. Fremantle himself in 1903-04 in the Lahore district of the Punjab. The methods employed were inoculation and evacuation. He considers that cats are useless for the destruction of rats in fighting plague, as they contract plague themselves; but we think that the experience of Lieutenant-Colonel Andrew Buchanan, I.M.S., shows that in several instances they have been of real value. With regard to evacuation of infected villages, if this be relied on as an effective measure or half-measure, the author rightly urges that it should be carried out with vigour; and that it is a mistake for it to be dependent upon local funds. If anything is to be supported by the general exchequer, surely it is the taking of measures for stamping out or preventing so terrible an epidemic. It cannot be said that anti-plague operations in India have increased in vigour during the last few years, and many will agree with Mr. Fremantle that more active measures are needed.

The beneficent effects of scientific research when practically applied are exemplified in chapters describing the work of the Pasteur Institute at Kasauli, owing to which hydrophobia in India has lost its terrors; of the institute at Parel, near Bombay, where cholera and plague prophylactics are prepared; and of the similar institute at Kuála Lumpúr, in the Federated Malay States, where the work of Hamilton Wright, Daniels, Fraser, and Stanton in regard to beri-beri is briefly referred to. Proceeding further east, Mr. Fremantle visited the Pasteur Institute at Saigon, in Cochin China, the municipal laboratory at Shanghai, and the Japanese Government Institute at Tokyo. At the last-named the work of Kitasato and Shiga was studied. The author cannot forbear a comparison between the progress achieved by direct government action in disease prevention in Japan during the last 35 years (due to a wise and liberal expenditure of public money) and the position of affairs in wealthy Britain.

The next subject dealt with is town-planning. An instance of development with a view to the future is adduced from Kuála Lumpúr, where the president of the sanitary board had, 25 years earlier, when sanitary engineer, laid out streets of 120 feet broad, thus showing considerable foresight and perseverance in the face of very natural opposition. Other instances adduced from the author's experience are Krupp's laying-out of Essen in Rhenish Prussia; Winnipeg, the great junction between Eastern and Western Canada, expected to become the largest city in the Dominion; and several of the greater American cities. The formation of garden cities and industrial villages is advocated rather than of residential suburbs, the idea being to check the inordinate growth of huge towns, and to promote the "colonisation" of the country.

In the chapter on the Aftermath of the Russo-Japanese War Mr. Fremantle gives an appreciation of the aims and international rank of Japan. He then advocates a Five-Power League of France, Russia, the United States, Japan, and Great Britain, in the interests of peace and progress; and he draws attention to the extraordinary development of China, and her inevitable expansion in the near future. In his concluding chapter, taking his text from Ross's dictum that it is "best to approach the prevention of disease, not so much from its humanitarian as from the economic point of view," the author states that it has been the aim of his book "to prove that health is a matter of business efficiency in imperial welfare." The establishment of an intelligence department and the issue of weekly bulletins, somewhat on the lines of those of the United States Marine Hospital Service, are proposed; also the formation of a permanent Advisory Council in London, to consist of experienced medical officers of health, one from each of the Dominion governments, together with "medical officers representing the several departments in Whitehall," and an equal number of lay administrators, permanently responsible for the consideration of health matters in their respective governments.

We congratulate Mr. Fremantle, and commend this book to all interested in the progress of the world, and more particularly of the Anglo-Saxon race. The story is extremely interesting. Numerous photographic reproductions add to its attractiveness. The only fault we have to find is that there is no index.

Differential Diagnosis Presented through an Analysis of 381 Cases. By RICHARD C. CABOT, M.D., Assistant Professor of Clinical Medicine, Harvard University Medical School, Boston. Profusely illustrated. London and Philadelphia: W. B. Saunders Company. 1911. Pp. 753. Price 24*s.* net.

ACCURATE diagnosis of medical cases upon rational and scientific lines is perhaps one of the most difficult subjects that the student has to master. It demands correct observation, a knowledge of symptoms, physical signs, and clinical methods, and considerable practice in marshalling in their due perspective the facts collected. The books on differential diagnosis are many and varied in scope and mode of treatment, since the subject seems to be a popular one for teachers of medicine to write upon. Many of these books consist of detailed descriptions of clinical methods and of their indications, while others are simply text-books of practical medicine. An original and suggestive treatment of the subject is therefore welcome.

Dr. Cabot, in his interesting book, gives instructive illustrations of the methods of diagnosis as they are used in actual practice. In his introductory chapter he says that his book is an attempt to study medicine from the point of view of the presenting symptom—that is to say, of the sign or symptom which the patient presents most forcibly to the examining physician. He goes on to explain: "We begin with the chief complaint and work inward and backward to the causes, the organic lesions, the evolution, probable outcome, and rational treatment of the case. Cases do not often come to us systematically arranged like the account of typhoid in a text-book of practice of medicine. They are generally presented to us from an angle, and with one symptom, often a misleading one, in the foreground." Dr. Cabot has taken 12 symptoms—viz., pain, fever, chills, coma, convulsions, weakness, cough, vomiting, hæmaturia, dyspnœa, jaundice, and nervousness—as the basis of his study of differential diagnosis. He admits there are many others which might have been discussed if space had permitted. The application of the methods of differential diagnosis is illustrated practically by a

study of 383 cases selected from his hospital and private practice, all of them being cases in which the diagnosis was not obvious and required careful working out. Each case is described in sufficient detail to enable the clinical picture to be realised clearly. The diagnosis is then discussed, and possible errors are referred to. The means used to confirm the diagnosis are described, and post-mortem appearances are referred to in some of the fatal cases.

An interesting and original feature of the book is the attempt to express in diagrammatic form the relative frequency of the common causes of each symptom discussed. The basis upon which these diagrams are constructed is an enumeration of the total number of cases of every disease treated at the Massachusetts General Hospital during the last six years. By this means about 180,000 cases were classified according to diagnosis, and the relative frequency of each disease in this material was thus roughly computed. In order to obtain the relative frequency of the symptoms studied in his book Dr. Cabot referred to the statistical articles available in the literature, and also investigated the frequency of the occurrence of the particular symptom in 250 cases of the disease under consideration. In addition to these diagrams a table is appended to most of the chapters summarising the chief features of the principal diseases of which the particular symptom under consideration is the prominent characteristic.

The distinctive feature of this book, which renders it especially noteworthy, is the discussion or commentary upon each case described. This is invariably clear, logical, and characterised by sound common sense. Mistakes are frankly acknowledged, and the lessons to be derived from them are pointedly emphasised. If we have any criticism to offer it is simply to regret that Dr. Cabot has not been able to deal in similar fashion with the other symptoms which he enumerates in his introduction. His book should be very useful to the senior student and to the practitioner in the elucidation of obscure and difficult cases.

Text book of Operative Surgery. By Dr. THEODOR KOCHER, Professor of Surgery and Director of the Surgical Clinic in the University of Bern. Third English edition. Authorised translation from the fifth German edition by HAROLD J. STILES, M.B. Edin., F.R.C.S. Edin., Surgeon to the Chalmers Hospital, Edinburgh; and C. BALFOUR PAUL, M.B Edin., F.R.C.S Edin., Assistant Surgeon, Royal Edinburgh Hospital for Sick Children. With 415 illustrations. London: Adam and Charles Black. 1911. Pp. 723. Price 30*s.* net.

THE world-wide recognition of the value of Professor Kocher's text-book on Operative Surgery rendered it essential that it should appear in an English version, and Mr. Stiles in 1895 performed a good work in translating the book into English. Now the third edition of the English version has appeared and it is based on the fifth German edition, so that the English reader has in his hands the latest ideas of the author. The characteristic of Professor Kocher's surgery has always been that it represents the personal opinion and the personal practice of the author, and that it does not attempt to describe all the methods and operations which have been, or now are, employed. This restriction has tended to keep the book of a reasonable size, though even now it has more than 700 pages. The style of the book is pleasing, and the author, in order to avoid the charge of egotism, has not employed the first person singular, which practice has been followed in the translation.

The book is divided into five parts. In the first the preparation of the patient, the disinfection of the hands of the surgeon and his assistants, the methods of sterilisation, the treatment of wounds, and the methods of anæsthesia are fully dealt with. In the second section the surgery of the heart and arteries is considered, and it may be mentioned that no less than 106 operations on the arteries are here described. The third section deals with the surgery of the nervous system. Section IV. is concerned with the surgery of the arm and leg, and Section V. with that of the head and trunk. The illustrations are exceedingly good. They show clearly what they are meant to portray, and colour is used where necessary. As the book is limited to the practice of one surgeon there are necessarily many points on which a discussion might be based. We prefer, however, to welcome whole-heartedly this account of the methods employed by a famous surgeon. To the two translators, Mr. Stiles and Mr. Paul, the thanks of English surgeons are due.

Die Röntgenstrahlen in der Gynäkologie. (*The Roentgen Rays in Gynæcology.*) By Dr. MANFRED FRAENKEL, Charlottenburg. With 14 tables and 46 illustrations in the text. Berlin: Richard Schoetz. 1911. Pp. 256. Price, paper, 7 50 marks; bound, 8.50 marks.

THE use of the X rays in gynæcology is rapidly becoming of considerable importance, and it appears that the time is not far distant when their employment will become more general in this branch of medicine than it is at the present day, and when the question of their routine employment in, for instance, the treatment of fibroid tumours will become a question for gynæcologists to come to some definite decision upon.

In this book Dr. Fraenkel has given a very full account of all the problems connected with this subject and has brought forward a mass of information of considerable value. After a preliminary chapter dealing with some experiments on animals the author gives an account of the results he has obtained in the treatment of a number of gynæcological affections. Out of 23 cases of myoma of the uterus some 75 per cent. showed a definite result, in some cases a marked diminution in the size of the tumour, and in all of these there was also a marked improvement in the duration and amount of the bleeding at the menstrual periods. This improvement was further associated with a marked amelioration of the general health. In 25 per cent. of the cases no result was obtained, and the patients did not react to the treatment. Dr Fraenkel's experience does not corroborate the view held by some, that the use of the rays increases the bleeding in some cases, and he does not exclude as unsuitable submucous fibroids. Further, he holds that the treatment should be applied early, before the tumours have attained any size, so that complications and the need of any operation may be prevented; if this is done, he maintains that the growth of most of these tumours can be arrested and the necessity for any operative interference in the future obviated. The effect on the growth of the myomata and the hæmorrhage from the uterus is no doubt to be explained by the action of the rays on the ovaries, and in this view the author is in agreement with practically all writers on this subject.

In succeeding chapters the effect of the rays on the ovaries is very fully considered, and a number of illustrations are given of both the macroscopic and microscopic appearances of ovaries which have been subjected to this treatment. The author recommends this mode of treatment also in cases of osteomalacia, dysmenorrhœa, and endometritis, while a chapter is devoted to an account of the effect it produces in cases of cancer. Dr. Fraenkel rightly prohibits its use in any but cases quite unfit for operative surgery, and he strongly condemns the practice of attempting to cure cases of malignant disease with the X rays instead of handing them over to the surgeon for immediate operative treatment. The necessity for accurate dosage and technique in this mode of treatment is very great, and this question is fully

discussed, with an account of numerous experiments carried out on animals for the purpose of obtaining accurate data as a guide in its clinical application.

The facts that the X rays produce a very definite effect upon both the maturation and the development of the ova in the ovary, and that they may lead to degeneration of the follicles, corpora lutea, and interstitial cells, lead the author to suggest that they might play some part in the determination of sex. By the use of the X rays it would be possible so to diminish the power of development of the ovum that the female pronucleus would always be the weaker and the male pronucleus would have the predominance, and if we accept the theory that the stronger cell produces its opposite as regards sex we might have the power, according to Dr. Fraenkel, of influencing the sex of the child. The question is much too wide a one to be discussed here, but the most recent views on the determination of sex would seem to show that the characters of both sexes are present in an ovum or spermatozoon, and so it would have to be assumed that any effect the X rays had on the ovary would be exerted on the one character and not on the other. It is a little difficult to believe in any such selective action.

There are many other points of interest in this work, such as the influence of the X rays in producing abortion and in causing sterility, and a consideration of the production of the latter condition by their means from both the medico-legal and the social aspects. The author also discusses their effect in the treatment of various nervous conditions of sexual origin.

Anyone interested in this subject should certainly refer to this work, which gives a very good account of the present position of this branch of therapeutics.

Hygiene and Public Health. By L. C. PARKES and H. R. KENWOOD. Fourth edition. With two plates and 86 illustrations. London: H. K. Lewis. 1911. Pp. 691. Price 12*s.* 6*d.* net.

THIS well-known text-book has now appeared in its fourth edition under the joint authorship of Dr. Louis Parkes and Dr. H. R. Kenwood, and has been revised and added to since the third edition was issued in 1907. In its new form it succeeds as well as its predecessors, both in presenting within moderate compass a review of the essential matters with which the present-day student for public health examinations should be acquainted, and in forming a useful handbook for reference by those who are actively engaged in public health work. At a time when medical officers of health are so often pressed to give all their energies and attention to problems of personal hygiene and administrative measures dependent on control over the individual, it is sometimes necessary to insist upon the importance of that aspect of public medicine which relates to the conditions of human environment that affect the community as a whole. It is essential to the student and to the practitioner of public health that he should be accurately informed on such matters as the requirements necessary for healthy housing, efficient sewerage and sewage disposal, and the means of securing pure air, water, and food. For this purpose the information imparted by text-books must be based on the broad principles aimed at, and must press into service physics, chemistry, mathematics, and any other branch of scientific inquiry that bears on the subject at issue. From such point of view this volume can in the main be cordially recommended. The chapters on water-supply, air and ventilation, and disinfection can be especially commended, and there is a capital statistical section. The summary of English sanitary law and administration is also well arranged and comprehensive, though it might with advantage have included a better account of the numerous statutory and other duties of a county medical officer of health. Perhaps the least satisfactory portion of the book is that which deals with food adulteration. This might very well be revised on the next opportunity, with special reference both to the inquiries of recent Government Commissions on food questions, and to the valuable series of special food reports which the Local Government Board has issued during the last few years. The table of common adulterations and adopted "standards" in particular needs to be brought up to date. On the other hand, there is an excellent chapter on school hygiene, containing much new matter concisely and practically arranged, which forms a valuable guide to the work required of school medical officers and the objects which they should seek to attain. The new edition deserves to be received with favour equal to that with which its forerunners met.

Nouveau Traité de Chirurgie. (*New Treatise on Surgery.*) Publié sous la direction de A. LE DENTU et PIERRE DELBET. *Affections Chirurgicales des Artères.* (*Surgical Affections of the Arteries.*) Par PIERRE DELBET et PIERRE MOCQUOT. Paris: J. B. Baillière et Fils. 1911. Pp. 348. Price, paper, 8 francs; boards, 9.50 francs.

THE treatise on surgery of which this is one section promises to be most important and valuable. The surgery of the arteries has of late increased greatly in importance since it has become recognised that they are less resistant to treatment than used to be thought. Formerly the application of a ligature to an artery was the utmost that a surgeon dared to do, but now it is known that it is possible to suture arteries and to perform a satisfactory anastomosis without a necessary liability to subsequent thrombosis or to the formation of an aneurysm. The risk of gangrene of the limb, when a large artery such as the femoral or the popliteal is wounded and the vessel is tied, justified the attempts made to suture the wounded artery, and the success which has in several cases followed this treatment shows that suture should always be attempted if it is any way possible. The method of treating aneurysm originally brought forward by Matas is fully described and discussed, and the great difficulties with which it is accompanied are set forth. The lesions of the several arteries are described in turn, and references to the literature of the subject are freely given. This volume is a very definite addition to an important branch of surgery and deserves careful study.

Vorlesungen über Harnkrankheiten für Aerzte und Studirende. (*Lectures on Urinary Diseases for Practitioners and Students.*) Von Dr. C. POSNER, a.o. Professor an der Kgl. Friedrich Wilhelms-Universität zu Berlin, Berlin: August Hirschwald. 1911. Pp. 355. Price 9 marks.

THESE lectures are intended rather for the general practitioner than for the specialist, for, as the author points out, the result of any disease of the urinary organs depends in great measure on the knowledge of the medical man who first sees the case, exactly as the result of a wound depends largely on the first dressing. He urges that those in general practice may usefully study special departments of surgery, though they will not have the opportunity of obtaining the operative skill of the specialist. The book is, we are told, based on the author's own experience, and it is clearly the product of a mind well versed in this branch of surgery, and capable of expressing clearly and simply the knowledge it possesses. Although the book has no illustrations, their absence is little noticeable, for the text is so clearly descriptive that the reader hardly feels the need for figures. The entire surgery of the urinary system is described, and the book is divided into a general part and a special part. In the former part the author deals with the general questions of etiology, diagnosis, and treatment, and with the methods of examination, including cystoscopy. In the

special part the inflammations of the various portions of the urinary apparatus are dealt with; then come tuberculosis, calculus, new growths, and nervous disturbances of the organs. The general practitioner by reading this book will get a better idea of the present state of the surgery of the urinary system than by studying the more elaborate and systematic treatises.

Dental Materia Medica, Pharmacology, and Therapeutics. By CHARLES W. GLASSINGTON. Second edition. London: J. and A. Churchill. 1911. Pp. 287. Price 6*s*.

THE author of this work deals with his subject in a clear and concise manner, and has succeeded in producing a most useful book for the dental practitioner. Special sections are devoted to local anæsthesia, the mummification of the dental pulp, and the application of bacterio-therapeutics to dentistry. The last section is written by Dr. D. W. Carmalt-Jones, who expresses the opinion that the streptococcus brevis is the principal initial cause of pyorrhœa. This organism in normal mouths is a harmless parasite, but he considers that it may become pathogenic in the same way as the bacillus coli communis does. Dr. Carmalt-Jones expresses a favourable opinion of vaccine treatment for periodontal disease.

We think that the value of the book for teaching purposes would possibly be enhanced if such expressions as "sponginess of the gums," and "harden the gums," were replaced by more appropriate pathological expressions. There are a few omissions; for example, we do not notice any reference to that useful drug calcium lactate. The author testifies to the therapeutical value of formamint, but clinical experience suggests that the use of this drug in the mouth may be attended with disastrous consequences to the teeth.

Die Morphologie der Missbildungen des Menschen und der Tiere. Herausgegeben von Dr. ERNST SCHWALBE. III. Teil. *Die Einzelmissbildungen.* VI. Lieferung. *Entwicklungsstörungen des Postfötalen Lebens.* Von Professor Dr. A. DIETRICH. Jena: Gustav Fischer. 1911. Pp. 50. Price 1.60 marks.

THIS is the sixth section of Part III. of a large work on the Morphology of Malformations, of which Part I. was published in 1906, Part II. in 1907, and the five previous sections of Part III. at various intervals from 1907 onwards. This short section deals with Disturbances of Development in Post-Fœtal Life, and treats first of infantilism (including Anton's classification) in its various forms; some forms of disturbance of development of the whole body, including dwarfs, cretins, and acromegalics, being associated with the state of certain ductless glands. Variations in individual organs are considered—e.g., malformations of the skull, including artificial deformities and deformities due to growth from too early closing of the sutures, microcephaly, deformities or malformations of the facial part of the skull, particularly of the jaws, and hyperostosis. Then follow deformities of the upper aperture of the thorax, deformities of the sternum, spinal column, and pelvis, hyperplasia of the vascular system, including abnormal narrowness of the aorta, and lastly, malformation of the genital apparatus due to various causes. The little brochure is an appendix to subjects dealt with in the parts of the work already published. It is an interesting and suggestive summary of a not too well-known department of morphology.

LIBRARY TABLE.

Reports from the Laboratory of the Royal College of Physicians of Edinburgh. Vols. X. and XI. Edited by Sir JOHN BATTY TUKE, M.D. Edin., and JAMES RITCHIE, M.D. Edin. Edinburgh: Oliver and Boyd. 1911.—Volume X. of this series contains the papers of workers in the laboratory of the Royal College of Physicians of Edinburgh published up to April, 1907. A tribute is paid to Dr. Noel Paton for the debt which the laboratory owes to him during his 16 years' tenure of office as superintendent. Volume XI. contains the contributions of workers up to the end of 1910. The College acknowledges the continued assistance of the Carnegie Trust. This volume, from the number of communications on neurological subjects, shows the advantages offered by the action of the laboratory committee in 1908 in setting apart a special room for the investigation of neurological problems. The papers have all been previously published in various scientific journals, but many will be glad thus to have them collected into book form.

Enteric Fever in the Tropics. By B. N. GHOSH, L.M.S. Cal. Univ., Lecturer on Materia Medica and Therapeutics, Calcutta Medical School and College of Physicians and Surgeons of Bengal. Calcutta: Hilton and Co. 1911. Pp. 40. Price 12 annas, or 1*s*.—This is a reprint of the author's papers published in various Indian and American medical journals. It contains some useful material of text-book type. The author speaks highly from personal experience of hydrochloric acid and oil of cinnamon as internal remedies in typhoid fever.

The Irish Motor Directory and Motor Annual, 1911-12. A Reference Handbook for Motorists. Edited by HENRY G. TEMPEST. Dublin and Dundalk: W. Tempest. Price 2*s*. 6*d*., post free 2*s*. 9*d*.—This book may prove a useful volume for Irish motorists, for it contains extracts from the laws governing motors, lists of hotels, repairers, and so forth. It contains, however, two features open to objection. Firstly, the stories and anecdotes, which are very numerous, are useless after they are once read, and make the book bulky instead of handy as a work of reference. Secondly, the publication of the list of car owners with their addresses seems a mistake, for it will enable anyone to find the name and address of the owner of any car and possibly to annoy him with some trivial complaint. In England this information can only be obtained by referring the number of the car to the police, which of itself is in some sort a protection for the much-maligned motorist against mere vexatious complaints.

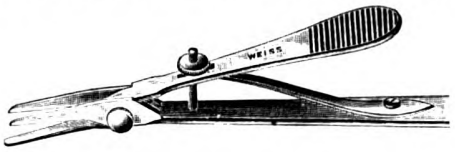
JOURNALS AND MAGAZINES.

Journal of Pathology and Bacteriology. (Official Organ of the Pathological Society of Great Britain and Ireland.) Vol. XVI., No. 1. Published from the Department of Pathology, University of Cambridge. Price 7*s*. 6*d*. Yearly subscription £1 1*s*.—Dr. T. McCririck of London, describing the streptococco-opsonic index in scarlet fever, erysipelas, and puerperal fever, notes that in scarlet fever the opsonic index to streptococcus pyogenes is low (about 0·7) during the first week of the disease, rising to normal or above normal as the temperature falls and the symptoms subside. During the second week the index on the average is 1·1, during the third week 1·2. At the onset of renal complications the index falls, and it is markedly below normal (0·5–0·7) in fatal cases. In erysipelas and in streptococcal puerperal fever the index varies in the same way as in scarlet fever. Further, Dr. J. M. Anderson of Glasgow records that the opsonic index towards streptococci in scarlet fever is low (about 0·7) at the beginning of the attack, gradually rising as symptoms abate and reaching normal about the third week of illness. In fatal cases the index is always low, and in most cases a fall accompanies the appearance of albumin in the urine. In cases treated with serum the index rises to, or above, the normal level more rapidly. Dr. C. J. Lewis of Birmingham, in a paper on the Micro-organisms present in Suppuration of

the Accessory Sinuses of the Nose, gives a profound study of the organisms found in 145 cases of suppuration in the accessory nasal sinuses. The numerous kinds found are described under the heads—(1) staphylococci, (2) streptococci, (3) pneumococcus, (4) M. catarrhalis and allies, (5) B. coli and Similar organisms, (6) B. diphtheriæ and diphtheroid organisms, (7) putrefactive group, proteus, &c., (8) B. mesentericus, (9) dental organisms, (10) anaerobes, and (11) spirilla, streptothrices, &c. Professor A. R. Ferguson of Cairo describes bilharziasis and malignant disease of the bladder as they occur in Egypt. He finds that bilharzia infection of the male bladder is found in 76 per cent. of the post-mortem examinations made by him in Egypt. Malignant disease of the bladder is also exceptionally common, the author having examined 40 cases during six years. All these were associated with bilharziasis, and were doubtless due to the chronic irritation set up in this condition. Of the 40 cases, only one was in a female; 34 were cases of epithelioma and 6 of sarcoma. Secondary growths in the heart muscle were present in five of these cases. Bilharziasis of the rectum is very common, but does not appear to lead to malignant disease. Dr. W. Henwood Harvey of Cambridge writes on auto-intoxication and experimental nephritis in rabbits. By repeated administration to rabbits of para-hydroxyphenylethylamine, either by the mouth or by subcutaneous injection over long periods, the author produced definite renal disease in 20 out of 33 animals. The changes are believed to begin with sclerosis of the renal arterioles, which is followed by definite degeneration of the glomeruli and tubules, leading to an increase of connective tissue. The whole kidney is a good deal enlarged, and the condition produced resembles some forms of chronic nephritis in man. Dr. W. K. Macdonald of Edinburgh, in a paper on Fat Removal in Peripheral Nerve Degenerated after Section, states that the fat which arises from the medullary sheath of a peripheral nerve after section is taken up by cells and carried away along the perivascular lymphatics. These cells resemble the compound granular corpuscles which carry away degenerated remains of fibres in the spinal cord. Dr. F. B. Gurd of New Orleans, in a paper on the Cytology of the Leprous Lesion, points out that the local lesion of leprosy begins with an accumulation of lymphoid and plasma cells; mast cells and eosinophile leucocytes are generally also present, and in some cases in which the leprosy bacillus is alone present neutrophile leucocytes are found in large numbers. Proliferation of endothelial cells then follows. Giant cells of the Langhans type, usually present, commonly show characteristic rounded vacuoles. Practically all the bacilli are inside tissue cells, especially in the endothelial and giant cells, also in lymphoid, plasma, and connective-tissue cells. The spherical masses of bacilli found in scrapings from leprous lesions are due to the accumulation of bacilli in the vacuoles, from which they are set free when the cell is ruptured. Dr. C. Price-Jones of London describes the Changes in the Blood and Bone Marrow produced by Hæmorrhage and Blood Destruction, and shows that the subcutaneous injection of phenylhydrazin produces in rabbits an anæmia characterised by a marked rise in the colour index and an increase in the diameter of the red cells. After bleedings of equal severity the colour index is also raised, though not to the same degree, and the increase in the size of red cells is only slight. These experiments, therefore, do not support the view that the raised colour index, which is characteristic of pernicious anæmia in man, is due to the fact that the stromata of the destroyed red cells remain in the body and form a stimulus to marrow activity. A careful study of the marrow indicates that phenylhydrazin has a direct tonic action on the hæmopoietic system as well as a destructive action on red corpuscles. This number also contains the Proceedings of the Pathological Society of Great Britain and Ireland at the meeting held at Oxford, July 7th–9th, 1911.

Paludism, No. 3, July, 1911.—This number of *Paludism*, the last to reach our hands, is full of valuable and interesting matter. The journal has increased in size, the present number comprising some 130 printed pages, with five full-page illustrations and a map. Major S. R. Christophers, I.M.S., who is in charge of the Central Malaria Bureau, Kasauli, has now joined Major S. P. James, I.M.S., as joint editor. The first item is an appreciative obituary notice of the late Sanitary Commissioner with the Government of India, Lieutenant-Colonel J. T. W. Leslie, C.I E., I.M.S., whose untimely death, on his way home on sick leave from India, the Indian Medical Service still continues to mourn. An editorial record, dealing with the newly established Indian Research Fund, we have already commented upon in our columns of Oct. 7th. Major James, the joint editor, contributes a note on some of the measures that have been taken to make quinine available to the poor in India, and his colleague, Major Christophers, follows with a short paper on the Selection of Unit Areas for Recording Data Concerning Malaria in India (with map). He also gives other articles on: (1) Aids to the Identification of Culicides other than Anopheles, with Special Reference to Indian Species, with plate; (2) An Investigation into the Prevalence of Kala-azar in Part of Upper Assam; and (3) Observations (with charts) on Graphs of the Spleen. rate and Average Spleens. Major W. H. Kenrick, I.M.S., Special Malaria Officer, Central Provinces, writes on the effect of endemic malaria upon the birth- and death-rate. Lieutenant-Colonel J. R. Adie, I.M.S., Special Malaria Officer, Punjab, contributes two papers, the first being some notes on infection among troops and native children at Delhi, and the second on a handy method of collecting adult anopheles (with plate). Major E. L. Perry, on special malaria duty, also contributes two articles, one being observations regarding malaria in the Jeypore hill tract and adjoining coast, the other being on the relation of the endemic index to the splenic index in epidemic areas in the Punjab. The Central Malaria Bureau describes (with plate) a system of mounting, examining, and preserving mosquitoes. A number of notes on mosquitoes (with plates) and a digest of recent literature connected with malaria, the latter extending over 26 pages, complete this most informing and helpful third number of *Paludism*. We understand that this publication will not in future be issued quarterly as hitherto, but at irregular intervals as occasion arises and material accumulates.

Jahreskurse für Ärztliche Fortbildung. (*Annual Post-Graduate Medical Course.*) Munich: Lehmann. Price 16 marks per annum.—The July number is devoted to gynæcology and obstetrics. Professor Winter contributes an article on placenta prævia, the teaching of which is very much on the lines of English text-books. Version and the de Ribes bag are regarded as the methods of widest application; *accouchement forcé* is condemned, and a limited field of usefulness is conceded to the various kinds of Cæsarean section. Dr. E. Sachs gives a most interesting article on the bacteriology of the parturient state. The methods of recognition of the presence of various germs in the genital canal and the relative importance of each, the great importance of the hæmolytic streptococcus, the possibility of prevention of infection, the avoidance of all operative measures in the presence of this organism, are some of his most important points. The serum treatment of puerperal infection appears to have given little prospects of success. Professor Martin deals with genital prolapse. He emphasises the very great importance of the muscles and fascia of the pelvic floor as the main support of the pelvic viscera, and



insists that all kinds of genital prolapse are to be regarded and treated in the same way as other abdominal hernias—i.e., by making good the defect in the muscular and fascial layers of the hernial orifice, which, in the case of genital prolapse, are the levatores ani and the visceral layers of the pelvic fascia. The use of pessaries is condemned, and it is held that the more complicated operations which aim at fixing the uterus from above are seldom required. The same author gives a short account of the use of the X rays in gynæcology, especially in the treatment of menorrhagia and myomata. He concludes with a very interesting discussion of the relative advantages of attacking uterine disease respectively by the abdominal and vaginal routes. Recent statistics by Wertheim and Schauta in relation to the radical operation for cancer of the uterus—in which the former uses the abdominal, the latter the vaginal route—are compared, with the astonishing result that the vaginal method gives as good remote results as the new or abdominal route, with fewer deaths from the operation.

The August number is occupied with the wide range of subjects included under the head of therapeutics. It is really an epitome of the more modern methods of treatment, and is, therefore, filled with matters of practical interest. Professor Kionka deals with the mode of action of the various purgative drugs in the light of recent observations by means of the X rays after feeding with bismuth. The influence of the drugs on the various movements of the different parts of the intestine and their effect in diminishing absorption or increasing secretion are described and discussed. The same author gives a short account of the uses of the carbonic acid baths, and analyses the various chemical and physical factors which bring about their action. Professor Strasser deals with the subject of hydrotherapy in special relation to the treatment of phthisis. He explains the hardening effect of cold bathing upon the system, which makes it of such great value in prophylaxis. The different kinds of baths and douches, together with the methods of their application, are given in some detail. A very important section of this article deals with the varying conditions of the patients which require special modifications of the baths. Dr. Determann contributes a short article on climatology, which reviews in a very concise manner the different factors that go to make a "climate," and the influence that each factor has upon different diseases, and he adds a most useful list of the special climates suitable for special diseases. Professor Strauss discusses the dietetic treatment of arterio-sclerosis with special regard to the questions of meat, milk, alcohol, and chlorides. A few pages of a somewhat condensed *résumé* of progress in nursing and nursing appliances are contributed by Professor Salzwedel. Professor Frankenhauser gives a highly technical article on electro-therapy, in which he explains the action of the different forms of currents on the body tissues. Dr. Holzknecht describes the recent advances in the diagnosis of diseases of the stomach by means of the X rays. He considers that this new method will render unnecessary the use of exploratory operations for diagnostic purposes. By a series of typical cases he shows how certainly the diagnosis was established in various patients who afterwards were submitted to operation. Dr. L. Freund deals with aspects of light therapy, some of the most interesting of these being the subjects of sunburn and of the sterilisation of drinking-water by exposure to the ultra-violet rays. Dr. Gudzent explains the physical properties of radium emanations, and discusses their influence in increasing ferment action, stimulating purin metabolism and leucocytosis. He concludes by showing the practical value of these actions in the treatment of various diseases—e.g., rheumatism, gout, and neuralgia. The whole of this number is full of facts of practical value.

New Inventions.

IMPROVED TWIN SCISSORS FOR SCLERECTOMY.

THE twin scissors devised for the purpose of making the essential part of Herbert's small-flap sclerectomy operation for chronic glaucoma, and described by me in THE LANCET of March 4th, 1911, were found capable of useful work, but they had certain defects in their working. The lateral hinge of the first pattern necessarily allowed sufficient play for the male blade to engage one or other of the female blades unequally, so that the cutting action was checked. The male or female blades were not always engaged, or, to use a term applied to motor-gears, not always in mesh, so that the cutting was jerky. Also there was no means of limiting the opening of the scissors. In the improved pattern here figured it is believed that these defects are completely

remedied. At the suggestion of Mr. W. G. Laws of Nottingham the lateral hinge has been changed to a central hinge which gives perfect stability. The male blade is now always in gear betwixt the female blades, and the female blades have been given a lateral spring, so that in cutting the sharp edges cling to, and shear along, the cutting edge of the male blade, just as the slight twist of the fingers causes the blades of an ordinary scissors to grip and shear along each other. A stop screw has been attached, so that the play of the jaws can be adjusted to a nicety and undue recoil of the spring checked. In the illustration the handle is cut off. The new twin scissors have been used already in several operations and the improvement is manifest. The new pattern is made by Messrs. John Weiss of Oxford-street, London, W.

N. BISHOP HARMAN, M.B. Cantab., F.R.C.S. Eng.

ALL-METAL SPINAL ANALGESIA SYRINGE.

THE All-Metal syringe for local analgesia which was devised by me a few years ago, and manufactured by Messrs. Allen and Hanburys, Limited, has been recently adapted for spinal analgesia, as depicted in the accompanying illustration. This syringe was originally based on the lines of Mr. A. E. Barker's well-known syringe, the great feature being the tightly fitting piston and its practical indestructibility. A

SCALE 1/3

large number of these instruments has been ordered by the War Office. The spinal needles (fitted with cannulæ which extend right to the tip) are carried in clips in the lid of the box. A hollow needle is also supplied through which the solution can be drawn into the barrel of the syringe and by means of which air can be expelled. A triangular-edged knife for puncturing the skin is included in the outfit. The needles and knife have been copied from Mr. Canny Ryall's spinal syringe.

Cosham, Hants. F. J. W. PORTER, Major, R.A.M.C.

THE LANCET.

LONDON: SATURDAY, OCTOBER 28, 1911.

The Lunacy Commission.

FOR several years past it has been generally recognised that the enormous increase in the work devolving on the Commissioners in Lunacy has made it imperative that their number should be augmented by the appointment of additional medical members. Since the passing of Lord ASHLEY'S Act, which established the Board of Commissioners on its present basis in 1845, the number of persons officially recognised as insane in England and Wales has increased fourfold, and now reaches the formidable figure of 130,000, but the number of medical Commissioners responsible for the supervision of this host of the insane and for the inspection of the establishments in which they are housed is still limited to three. It is no reflection on the distinguished physicians who have held these offices to say that the work imposed upon them under these conditions has been beyond their powers. So intolerable, indeed, has the position become within the last few years that it has been necessary to find an immediate remedy without waiting for that entire recasting of the machinery for the supervision of the mentally defective which we have been promised since the publication of the report of the Royal Commission on the Care and Control of the Feeble-Minded. Legislation has accordingly been initiated, and the Lunacy Bill which was before Parliament this year provides for the appointment of two additional Commissioners. It does not, however, expressly require that they should be medical men, and we understand that in certain quarters efforts are being made to secure that one of them shall be a legal representative, thus giving four lawyers and four medical men as paid members of the Board.

It is hardly conceivable that the authorities in whose hands these appointments rest should entertain so extraordinary and reactionary a proposal, but the very fact that it should have been put forward at all makes it desirable that medical opinion should be expressed very explicitly on the matter. It is not a question of securing positions of patronage for the members of a particular profession; if it were merely that, the general public at all events might be content to take a detached view of the issue, satisfied from past experience that the claims of the legal profession are not likely to be under-stated. The question goes much deeper: it not only concerns the welfare of a very large number of sick persons, but also affects the consideration of a bio-social problem which is of vital importance to the community. The demand for further legal representation on the Lunacy Commission is in effect the reaffirming of the tradition which separates insanity from disease and regards the lunatic somewhat in the light of a wrong-doer to be punished and not as a patient to be treated. The medical profession has consistently striven to combat this bad tradition, and thanks to its strenuous efforts the whole tendency of public opinion and legislative action from the days of PINEL has been in the direction of extending to the insane the privileges which an enlightened humanity accords to the sufferers from more patently physical diseases. And if this change of attitude has immeasurably alleviated the lot of these unfortunate invalids, it has had an indirect influence of even greater ultimate importance in stimulating that scientific study of insanity by which, and by which alone, we may hope to discover, and hence to counteract, the causes of a malady that constitutes at once a heavy burden on the community and a danger to its vitality. The recognition of this truth that insanity is a disease inspires the whole system of asylum treatment which it is the special function of the Commissioners in Lunacy to supervise; the statutory duties imposed on the Commissioners by the Lunacy Acts are chiefly concerned with medical questions; the annual reports in which they render an account to the public of their performance of these duties deal mainly with matters of strictly medical science, with the discussion of problems of etiology, with the investigation of zymotic diseases specially prevalent amongst the inmates of asylums, and with kindred topics.

It is hard to imagine in what manner the discharge of these functions could be promoted by an addition to the already large legal element on the Board, but it is not at all hard to conceive that such a deplorable step must react injuriously on the scientific position of English psychiatry, and might tend to revive in the public mind the unfortunate errors and prejudices which formerly prevailed with reference to the insane. With the addition of two medical Commissioners, the medical representation on the Board will still be quite inadequate, as may be seen by comparison, we will not say with continental countries, but even with Scotland and Ireland. In Scotland, where the insane number some 20,000, there are two senior and two junior medical Commissioners in Lunacy, and in Ireland the supervision of the 25,000 lunatics is entrusted to two medical inspectors. It can hardly be suggested that there is any extravagance in the arrangement by which in this country five medical men are expected to discharge the same functions for 130,000 patients. And in this connexion we may remark that the anomalous position of England with regard to the medical supervision of the insane is of comparatively recent origin; the Metropolitan Commissioners, who, prior to Lord ASHLEY'S Act, exercised the powers vested by that Act in the Commissioners in Lunacy, included five physicians originally, and by subsequent legislation the number was raised to seven; and at a still earlier period, under GEORGE III., no less than five physicians were deemed necessary for the inspection of the insane in the metropolis of that day. Some of our contemporary politicians do lip-service to the ideas and the spirit of modern science: they have now an opportunity of showing whether in their appreciation of the fact that insanity is a disease they are at least as enlightened as were their predecessors of the Georgian era.

The Battle of Monism and Dualism.

THE prominence given in recent years to investigations by the psycho-physical school has led to the belief that just as "sensation" and "memory" can be expressed in terms of logarithms, so in the long run all mental phenomena might be reduced to arithmetical processes; whilst the more advanced advocates, of whom TITCHENER and KÜLPE are prominent exponents, have maintained that there is no necessity for any theory of an "activity-process," such as the conation forces of will and attention, but that mind and brain are practically the same thing, the former being just the necessary result of the action of the latter. But this interpretation does not satisfy those who, from introspection, and after consideration of the objective statements of experience by a large number of individuals, feel that the physical school is not quite convincing, that it does not fill up the gap between metaphysics and physiology, and that there is a realm of spiritual as well as of corporal body which has not so far been found capable of scientific exposition, though it may be accepted as a continuation of the line of evolution which, starting with the potentialities of living protoplasm, has not yet completed its course. The epithets of Atheism and Agnosticism which have been hurled by some over-strenuous religious corporations against the so-called materialist school have been unjust, because the upholders of the latter have declared themselves open to conviction, whilst merely affirming that present knowledge did not authorise belief in what is, so far, incapable of scientific demonstration. However, in those departments of biology which deal with actual facts, and draw up theories afterwards, there has been of late the exhibition of a tolerant attitude towards inquirers who, finding themselves face to face with what they cannot explain, are willing to weigh the feasibility of theoretical considerations which might, if they could be proved to be realities, show the real connexion between the psychical and the physical. There are inquirers, in other words, who, whilst believing in the authority given by the balance and the microscope, are ready to conceive that there are processes which for their demonstration require finer adjustments, perhaps even means of an order different from those which we at present recognise.

Professor J. S. MACDONALD, in his admirable presidential address to the Physiological Section of the British Association at Portsmouth, has recently thrown his considerable weight into the scale on the side of Dualism. He pointed out that there was no scientific evidence to support or to rebut the doctrine that, whilst the brain was possibly affected by influences other than those which reached it from the sense organs and from the different receptive surfaces of the body, it was still possible that it was an instrument traversed freely by an unknown influence which found resonance within it; and it is clear that an instrument, shaped in the embryo by a certain set of conditions, might in course of time respond to the play of some new influence which had taken no immediate part in fashioning it. The essential point for the moment was, Professor MACDONALD allowed, that there was some loophole for the view that mind was not directly associated with life or living matter, but only indirectly with certain dispositions of dynamic state that were sometimes present within certain parts of it. Where there was evidence of mind the view was that it represented a force acting from without upon what was still no more than matter involved in certain chemical and physical states. He put forward this view as an expression of belief rather than of opinion, and not as based on evidence or in any way a statement of demonstrated or demonstrable fact. Professor C. S. SHERRINGTON and Professor WILLIAM STIRLING intimated their acceptance of an address so full of suggestions for further valuable research in the field of physiology—and this acknowledgment of the intimate connexion between physiology and psychology is a proof that the expositors of the most exact scientific methods are willing to admit the possibility of the ultimate inclusion within the realms of experiment and demonstration of what has up to now been treated as a domain merely for dialectics and empiricism.

In a lecture "On the Occult," given at the Medical Graduates' College and Polyclinic in June, 1910, Dr. CLAYE SHAW expressed some ideas which are strikingly in harmony with those of Professor MACDONALD. The lecturer put forward the proposition of an external agency, a world of force which requires for its display the human mechanisms. If there are external forces which are able to affect the human mechanism it is surely not possible to deny that an individual may be moved to speak or to act in a way unknown to himself by some influence of which he is the appropriate medium. If the body and the brain are but instruments for the working of this force, then our actions denote that some changes may be going on in this force for which there is in us no responsibility—we are just puppets, as it were the keyboard of an electric installation. Viewed thus man is a necessary complement of this force, and one object of his creation is merely that of a force terminal, an Æolian harp which discloses the motion of winds which cannot be seen. It may be urged that all this is pure spiritism, that it gives us no more solid base than have the spiritualists and mediums of the "occult" performances of recent and ancient times. This may be conceded; but the great point is that followers of the exact sciences of to-day find themselves now in the position of being able to acknowledge the validity of agencies other than those at present at their command and under their control, and, having taken stand on a new platform, they are ready to investigate the existence of this Soul, Mind, Force, or whatever name be given to it. They are prepared to discover the laws under which it acts, and to devise experiments (possibly of an order very different from the means now employed) with the hope of attaining nearer to final truth. If such an achievement is beyond our present resources we must still go on in the hope that by constant attention to, and familiarity with, the processes observed we may ultimately develop a condition which enables us to see clearly what just now is no more than acceptable speculation. Just as we observe to-day a greater tolerance in the teachers of spiritual truths towards the exponents of scientific facts and theories, so do we welcome the *rapprochement* between the adherents of the psychical and the physical,

as shown by the agreement that the gap between the two may be bridged across, if not even actually filled up and obliterated.

The Medical Profession in India.

ON several occasions recently attention has been drawn in our columns to the dissatisfaction that exists in the Indian Medical Service at the present time; this prevails not only in regard to the pecuniary emoluments offered, but also in a considerable degree to the conditions of employment generally. The high traditions of this service, the record of pioneer work accomplished in many branches of medical science, the long roll of distinguished physicians and surgeons who have worked, often through a life-time, in our great dependency, have combined to place it in the first rank amongst the spheres of occupation open to the young medical man when he is choosing his career. Within the last few years, unfortunately, various circumstances have combined to diminish its attractiveness, as has been evidenced by the falling-off in competition for admission to its ranks; and it is clear that if the ruling authorities desire to have the best class of medical practitioner in their service, as until lately has undoubtedly been the case, they must increase the emoluments and render the service more attractive.

To pass, however, from the individual aspect, or personal point of view, if we regard the matter from an administrative standpoint, it is a fair subject for discussion whether the time has not now arrived for comprehensive reorganisation. As at present constituted, the Indian Medical Service is officially and primarily a military service; all its members enter through the military portal, undergo military training, and possess military rank and titles. One section of these officers remain in military employ for the greater part of their career; the other and larger section form the main body of the profession throughout the country, either as medical practitioners or as health officers. The arrangement had its origin in the conditions of the birth and development of British rule in India; this began as a trading venture, but by circumstances was compelled to advance by force of arms. It is still absolutely necessary to maintain a large armed force in the country, though happily our relations with the various populations and their native rulers are most friendly. It has always been, and still is, considered necessary that the medical service of the army should be capable of immediate expansion in the event of warlike operations being undertaken, that part of the medical establishment that is employed in civil duties being regarded as the reserve from which any required increase in *personnel* might be drawn. The condition of things is not, however, satisfactory. For those medical officers who have chosen military employ and look forward to promotion to administrative rank in natural course it often happens that disappointment is in store, owing to the return to military duty over their heads in the administrative grades of senior officers who have passed most of their time in civil employ. More serious than this is the risk of inefficient medico-military administration when it is placed in the hands of officers, however able they may be, who have been spending their best years in civil practice. It cannot be said that a college professor or the able governor of a jail is necessarily or naturally an efficient army medical administrator in these days of advanced military medical requirements. On the other hand, the medical officers who are employed on military duty find themselves "associated with an archaic system of regimental service, characterised by a total absence of opportunity for acquiring initiative, experience, or responsibility, and for keeping up a reasonable standard of professional knowledge."

These are the words of a well-informed writer in the *Allahabad Pioneer* for July 6th, 1911. In the opinion of this writer another problem, and one of an extremely delicate nature, is the presence of an increasing number of Indians in the service, and he goes so far as to say that the Indian is not a suitable element on the military side of the Indian Medical Service. The same writer considers that the fundamental defects of this service consist in (1) attempting too much by doing both civil and military duties; (2) the present system of recruitment, which is not suited to the military side of its functions, and is paralysed by the top weight of the civil side; and (3) the present regimental system which is inconsistent with either military or professional efficiency. His remedy would be to divorce the civil side absolutely from the military, and to recruit the latter entirely from Europeans. He inclines to the formation of an Imperial Medical Service (in preference to any local *cadre*), as in the case of the Royal Engineers, who have men on the permanent Indian establishment and yet belong to an Imperial service. As for the civil side, which in this event would be the true Indian Medical Service, it should be a purely civil *cadre;* the argument that it is required as a military reserve the writer (who pessimistically signs himself *Mene*) does not think applicable at the present time. Any number of men could be obtained from England in three weeks, if occasion required, as was shown at the time of the South African war. The civil side could recruit freely from Indians. This writer is, however, not in favour of maintaining the present monopoly of the Indian Medical Service in regard to civil surgeoncies. He would gradually reduce these in number, thereby fostering an independent medical profession "presumably European." The reorganised civil medical service should be a true public health service, with activities in preventive as well as in clinical work, forming part of a secretariat on the lines of the Local Government Board. Such are the views of the Allahabad correspondent. We understand, and can readily believe, that, with the greatly increased communication between East and West, the large numbers of Indians who come to Europe for their professional education (a substantial proportion of these being students of medicine), and the increased opportunities for education generally, there has arisen a great desire on the part of the cultivated and intellectual youth of India to enter on a medical career on the same terms of equality with Europeans, as they have long had in the legal profession. They demand equality of opportunity—a fair and open opportunity for practice. No one believes that this can be denied them for ever. But we have to consider the large population of our own countrymen whose lot is cast in that "Land of Regrets"; for them, and especially for

their wives and families, whose interests cannot be ignored, there are the weightiest reasons for the maintenance of a numerous body of British-born medical practitioners, in the civil as well as in the military service, distributed throughout the country. So long as it is good for India to be governed by Britain, so long must precedence be given to every condition which inevitably arises from that fact. As pointed out by another correspondent of the *Pioneer* (July 26th, 1911)—not himself a medical man—the reasons for the necessity of this presence of British medical men "rest on the highest moral foundations, before which reasons the private ambition of any limited class of practitioners must give way." Moreover, for positions of the principal responsibility, needing long experience and matured judgment, and, more than all, that ability to deal with emergencies which is certainly not characteristic of the literary and cultivated, as distinct from the warlike, native of India, we still need, and shall need for long, the services of our own countrymen in the important grades of civil administration. With these reserves we should welcome the gradual development of a medical service of Indians for Indians.

In one line of practice we should like to see more rapid progress—viz., in the development of female medical education. The scope for the work of the woman doctor is enormous; this is a field in which we think Government might move more quickly than they have been doing up to now. There is no question here of comparative fitness for administrative duties and responsibility. Throughout India there are some 150 million women and girls, for a large proportion of whom medical aid under present circumstances is non-existent or inefficient; this is the crying need of the country, and to supply this the medical education of suitable women of native races should be largely developed. For general medical practice the field is already open to the native born Indian, but we are of opinion that careful selection should be exercised in regard to the education of Indian students for the medical profession. It is not all who are fitted for it at present; the conditions of a public service demand more than ability to pass examinations, and apparently such ability among the Indians is even less a testimony of real fitness than in the case of Europeans. Nevertheless, the development of a native medical profession is proceeding, but it must advance gradually for the results to be of permanent value. There remains to be mentioned the case of the British or European medical men practising in India on their own account; they are practically limited to the Presidency towns, one or two other large centres of population, and a few districts where there is a considerable number of unofficial British residents. We are not aware of any widespread desire on their part for any interference with their freedom of contract or conditions of practice.

BANGOR DISTRICT NURSING SOCIETY.—At the annual meeting of this society held in Bangor, co. Down, on Oct. 19th, Lady Hermione Blackwood gave an address, illustrated with limelight views of "district nursing." The slides represented religious nursing orders in early times, Chaucer's Doctor of Physicke, the Knights of St. John, and nurses going their rounds in the west coast of Ireland. The lecture was greatly enjoyed.

Annotations.

"Ne quid nimis."

THE EXPERIMENTAL PRODUCTION OF APPENDICITIS.

WE publish in another column of this week's issue of THE LANCET an interesting paper which was communicated to the Pathological Section of the Royal Society of Medicine on Oct. 17th by Dr. F. J. Poynton and Dr. Alexander Paine. It is well known that these observers have in a series of researches isolated from the lesions of cases of acute rheumatism and some of its complications a diplococcus to which the name of diplococcus rheumaticus has been applied, and by the agency of which they have produced experimentally in rabbits arthritis and cardiac lesions. In the present research they have used a diplococcus isolated from the fluid drawn from the knee-joint of a boy suffering from a first attack of acute rheumatism, and they have invariably employed young rabbits for the intravenous inoculations carried out with it. In a certain number of the rabbits, in addition to the arthritis and the cardiac lesions when these were present, they found evidence of inflammation of the vermiform appendix, the histological features of which seemed to demonstrate that it was the result of an infection from the blood stream. In some of the cases the diplococci were demonstrated in these lesions, while in one case in which reparative processes were in progress they were not found. The characters of the appendicitis varied somewhat in the individual cases; in one a very early inflammation was found, in another a severe degree, while in a third an ulcer was noticed. In one case the middle part of the appendix was ballooned, while in another there was early peritonitis without perforation. It is interesting to note that in some of the rabbits a mucous diarrhœa occurred as a result of the injection of the diplococcus, and in two intussusception was found post mortem. Dr. Poynton and Dr. Paine disclaim any priority in regard to the demonstration of the occurrence of appendicitis as a local result of a general blood infection, and refer to some observations by Adrian published ten years ago. He showed that in rabbits appendicitis could be produced by the intravenous injection of various organisms such as streptococci, staphylococci, pneumococci, typhoid bacilli, and the colon bacillus. Dr. Poynton and Dr. Paine point out that in their cases there was no concretion or foreign body in the appendix, and that the changes commenced deep in the wall of that structure, facts which they regard as opposed to the view of Aschoff that the disease in man starts from within the lumen. They also suggest that the ordinary lesions in human appendicitis could be explained readily by their results in rabbits. Their observations are of considerable interest in regard to the etiology and pathology of this condition, and they deserve careful consideration. If the organism described is regarded as the causal agent of rheumatic fever, it gains additional interest from the support it affords to the view which has often been expressed that there is a relationship between acute rheumatism and appendicitis; but in order not to confuse the issue in regard to the origin of appendicitis from blood infections, Dr. Poynton and Dr. Paine avoid employing the specific name of the diplococcus with which they have worked.

THE SLOW PULSE OF JAUNDICE.

IN 1864 Bouillaud called attention to the association between bradycardia and icterus which he had noted, especially in cases of catarrhal jaundice. In other forms of jaundice, however, the same phenomenon is occasionally

noted. The pulse-rate rarely falls below 40 in such cases, being usually somewhere between 40 and 60 per minute. At the present time, when so much time and energy are being devoted to the study of bradycardia, this association is of particular interest. We know that a slow pulse may be due either to retardation of the whole heart or to "heart-block"; the form of the latter which has been most thoroughly investigated is that in which the stimuli to contraction are arrested either by organic disease or by exalted vagus tone in their passage through the auriculo-ventricular bundle. A bradycardia of toxic origin, such as that met with in jaundiced persons, is of special interest, because it may possibly afford an answer to the question, Can direct poisoning of the auriculo-ventricular bundle without demonstrable gross lesion interfere with the conduction of impulses? The work of Lewis and Oppenheimer on asphyxial heart-block suggests an affirmative answer to this query. The latest work on icteric bradycardia, by Danielopolu of Bucharest, published in the *Wiener Klinische Wochenschrift*, No. 39, 1911, shows that in the two cases investigated by him there was no question of interrupted conductivity. Both patients were suffering from catarrhal jaundice, and in both the rate of the pulse was about 48 per minute, counted with the patient lying down. In both cases injection of atropine sulphate (2 mg.) was followed by a quickening of the pulse-rate up to 100 or more per minute within three-quarters of an hour. The rhythm was also altered by deep inspiration and by swallowing movements and by changes of posture. More definite proof of the implication of auricle as well as ventricle in the slow rhythm was afforded by polygraph tracings, which showed that the slowing was a disturbance belonging to the class of sinus irregularities in which each ventricular systole was preceded at the normal interval by an auricular systole. It is true that these results, so far as the atropine acceleration is concerned, are in contra-indication to those obtained by certain other investigators, whose work Danielopolu quotes; these, however, are seriously discounted, in his opinion, by the fact that the dose of atropine used in the application of the test was too small. There is, therefore, no sound evidence of a myogenic origin for the bradycardia of jaundice.

FINSEN LIGHT AND TRACHOMA.

TWO interesting papers on the action of Finsen light on trachoma have recently been published in Finland by V. Grönholm and K. A. Heiberg (Finska Läkaresällskapets Handlingar, vol. liii., 1911). Till a few years ago the technical difficulties which this treatment involved seemed to exclude its application to structures in the neighbourhood of the eye. Lundsgaard, however, demonstrated experimentally that the conjunctivæ tolerate considerable exposure to the ultra-violet rays, and that technical details such as screening the eyeball and compressing the diseased tissues so as to render them suitably anæmic could be effectually carried out. These difficulties being overcome, Finsen treatment promised good results in trachoma, as the ultra-violet rays have a selective action on cellular tissue in which trachomatous areas are rich, while connective tissue is relatively immune to these rays. The treatment was begun in 1907 by Lundsgaard. After 12 exposures lasting 10 to 35 minutes each the conjunctiva became pale and smooth without marked cicatrisation. All the trachomatous areas disappeared, and after an interval of three years there was no relapse. The reports of Grönholm and Heiberg deal with 72 patients and 109 trachomatous eyes. There was no selection of cases. All varieties were treated, except such as presented very slight disease or extensive involvement of the cornea. After exclusion of 11 eyes, which were not systematically treated, the immediate result of the treatment showed recovery in 79 (81 per cent.) and improvement in the remaining 19 (19 per cent). Unfortunately, it is at first difficult to decide whether a permanent cure has been effected or not, for the structures about the eye are still so hyperæmic two or three weeks after the treatment that trachomatous tissue may be hidden in a conjunctival crypt or in the walls of the lacrymal canals. Months even may pass before such a focus becomes evident, and a probation period of a year is therefore necessary before a permanent cure can be claimed. After a period of 12 to 17 months 64 eyes were examined and reported on. Thirty-six (56 per cent.) were still healthy, 21 (33 per cent.) had relapsed, and 7 (11 per cent.) were still infected. Of the 19 eyes which were relieved but not cured at the conclusion of the treatment, 9 were subsequently examined, when 6 were found to be radically cured. Although the percentage of relapses is high it is, however, considerably lower than with other forms of treatment, including excision. Probably in a certain number of cases the reappearance of trachoma was due not to relapse but to reinfection either from the patient's other eye or from another patient. In either case the disease ran a mild course on its second appearance. It was found to be rather the nature of the disease than the thoroughness of the treatment upon which recovery depended, for the best results were obtained where the disease was early and associated with considerable hypertrophy of the surrounding structures even when only one exposure was given, whereas relapses were frequent in spite of repeated exposures when there was considerable cicatrisation present. The whole of the conjunctiva can be treated by one exposure of 10 minutes, and its efficacy is increased by a preliminary expression of the trachomatous granules. The reaction which follows expression subsides in a week, after which an exposure is given, the resultant reaction lasting a week or two. In an uncomplicated case, therefore, the period of treatment may be less than one month; but when complications such as hyperæsthesia are present 2 to 5 small tentative exposures are required which prolong the treatment considerably. With bilateral disease 4 to 6 weeks' treatment is necessary. Nine cases which had previously been treated in vain by expression and copper sulphate, in some instances for many years, were treated by expression plus light treatment: there was improvement in all, and permanent recovery in 4. The new treatment is not entirely free from dangers. Pannus or corneal ulceration, which existed in 15 cases before treatment, grew worse, and in seven cases small peripheral ulcers appeared on a previously healthy cornea. In three cases corneal opacities were produced which permanently affected the patient's vision. The treatment is therefore primarily indicated in cases which present a healthy cornea; when this is involved or the eye is inflamed small conjunctival areas must be successively treated, and the reaction induced by one exposure must be allowed to pass off before another is given. The writers conclude that in suitable cases treatment of trachoma by Finsen light is superior to every other method.

TABLE UTENSILS AS A MEANS OF SPREADING INFECTION.

IN an interesting note in the *Münchener Medizinische Wochenschrift* of Oct. 17th Professor A. Ritschl of Freiburg draws attention to a possible factor in the spread of infectious conditions of the mouth, nose, and pharynx, which he believes to be insufficiently recognised in most households—viz., the table utensils, such as the forks, spoons, and glasses, which come into contact with the mouth. He points out that these are usually washed altogether, often very perfunctorily, and then dried upon the same cloth, so

that it is not surprising if the infective agent gets distributed by this means. He states that in his own family the utensils used by any member suffering from an infectious condition are separately sterilised in boiling water. One of his children having contracted mumps at school recovered without communicating the disease to any other member of the family. Professor Ritschl insists upon the importance of strict measures in regard to this matter in restaurants, hotels, and pensions, and he is of opinion that if these precautions were adopted it would be less common than at present for people to complain of "catching cold." We believe that precautions in regard to this matter are generally adopted at sanatoriums for the treatment of pulmonary tuberculosis, where this danger is recognised, and at hospitals and public institutions in this country; but Professor Ritschl's note may serve to draw the attention of the public to this question, since there can be little doubt that the ordinary process of washing, unless carried out thoroughly with very hot water, is not calculated to destroy infective organisms.

THE ABSENCE OF ALTMANN'S GRANULES IN THE DIAGNOSIS OF MALIGNANT DISEASE.

IN most of the living and healthy cells of the body there are certain granules which can be demonstrated by special methods of staining; they were first described by Altmann, and are generally known by his name. In the tenth report of the Cancer Research Laboratories of the Middlesex Hospital four important papers occur dealing with the interesting point that Altmann's granules are not to be found in the cells of malignant growths. As Dr. W. S. Lazarus-Barlow remarks in his article in the same report on the progress of Cancer Research during the last ten years, the discovery of the absence of Altmann's granules in carcinoma and sarcoma has afforded the first indubitable evidence that the cancerous cell differs in its metabolism from its ancestors, the healthy cells, and it has also afforded a means of differentiating between certain conditions hitherto difficult or impossible to differentiate by microscopical examination and a matter of doubt clinically. It is now possible to determine whether a given mass of redundant tissue is sarcomatous or inflammatory, and with a further extension of our knowledge in this direction a still wider application may be hoped for. Altmann's granules are present in the cells of nearly all normal tissues, the chief exceptions being unstriped muscle, squamous epithelium, and the pyramidal portion of the kidney. The first paper on this subject in the report is by Dr. Hector A. Colwell and Dr. Henry Beckton, and it deals with the chemical nature of the Altmann's granules in the kidney. The granules are wanting in the pyramidal portion of the kidney, while they are abundant in the cortex, and the contrast of the two portions is very strikingly made manifest when the granules are stained. The evidence derived from many experiments described in this article goes to show that the granules are protein in character. The same observers have contributed a paper on the effect of various reagents on the demonstrability of Altmann's granules, and the conclusion is formed that operation material placed in moderately thin slices in formalin is available for examination for the granules, provided that it be transferred to formol-Müller solution within a day or two. Dr. Beckton and S. Russ have examined the effects of radium emanation on Altmann's granules. It was found that the emanation caused the disappearance of the granules from all the tissues examined. A note by the late Miss Theresa de G. Miller also is well worthy of mention; it details the effect of many stains on these bodies, and the conclusion is confirmed that the granules are acid in character. Our brief summary does not do justice to these valuable papers, but, useful as they are, they are only as it were the first fruits of a new line of investigation into the nature and diagnosis of malignant disease. We may feel sure that in the near future valuable assistance will be given to the clinician in determining the nature of doubtful growths. As to the significance of the absence of Altmann's granules from malignant tumours it is as yet too early to speak, but this question will no doubt be settled before long.

WALNUTS AND WINE.

To not a few people there is a fascination about walnuts and wine. Walnuts, in fact, are seldom discussed without reference to port, but the association is physiologically unsound, especially as the invariable custom is to eat the walnuts and drink the port after dinner. The food value of walnuts is very high: they are very rich in fat, containing as much as 63 per cent., while the proteins amount to nearly 16 per cent. It has been calculated that 30 large walnut kernels contain as much fat as 2¾ lb. of lean beef, and yet the walnut is used as a supplement to a square meal. Added to this the glass of port, say two fluid ounces, contains besides 180 grains of alcohol 70 grains of grape sugar. In the combination, therefore, we have all the elements which make for a complete diet—viz., fat, protein, carbohydrate, to which may be added mineral salts. Port and walnuts after a meal are therefore, from a nutritive point of view, "ridiculous excess." The digestive disturbance to which this excess may easily lead is, in fact, the price paid for an æsthetic indulgence. The peculiar palatability of a crushed mass of walnuts occasionally moistened with an elegant port is in part attributable to the smooth creamy emulsion which is formed. An emulsion presents elegant flavours in a way which increases their appreciation. It should be added that both walnuts and port wine contain tannin, which is unsuited to some constitutions.

RADIUM IN INOPERABLE CANCER OF THE CERVIX UTERI.

AT a meeting of the Société Médicale des Hôpitaux of Paris on July 28th, M. H. Rubens-Duval and M H. Cheron communicated an important paper on the treatment of inoperable cancer of the cervix uteri by the more penetrating rays of radium. In general great amelioration was obtained, and in some cases the lesions cicatrised and the patient recovered apparently perfect health, which was maintained for several months. Some of the results were possibly cures. In one case radium was last applied on Feb. 17th, 1910, and since that date there have been no signs of the disease. More cogent than the clinical evidence was the microscopic examination of nine specimens. Two were removed post mortem. One was taken from a patient who had died from intercurrent infectious endocarditis and the other from a patient in whom the treatment was suspended when symptoms of generalisation of the disease appeared. The remaining seven specimens were obtained by hysterectomy from patients in whom the disease, at first inoperable, under radium regressed sufficiently to become operable. As soon as the regression, though manifestly partial, was sufficient to allow the cancerous uterus to be removed, the intervention of the surgeon was requested, as it was thought less dangerous to risk hysterectomy than dissemination of the disease while further local regression was being attempted. Hysterectomy was not always rendered possible, for the sclerosed uterus and vagina sometimes remained intimately united to the bladder and rectum. In such cases radium therapy alone is possible and ought to be followed until cicatricial tissues are obtained in which examination no

longer shows epitheliomatous manifestations. Of the seven specimens obtained by operation, four showed zones of epithelioma regressing but sufficiently extensive to be perceptible to the naked eye. This was only to be expected, as the treatment was suspended as soon as the improvement was sufficient to allow operation. These specimens showed destruction of the epitheliomatous cells under the influence of the radium rays. The following case is an example of how an inoperable case may be rendered operable. It was thus described by Dr. Lejars at the Société de Chirurgie on June 8th, 1910: "A woman, aged 47 years, was sent to me at the end of 1908 with a large epithelioma of the cervix extending into the anterior fornix and complicated by peri-uterine infiltration. The case appeared inoperable. Three applications of radium were made at intervals of a month. On each occasion an apparatus containing 5 centigrammes of the radium salt was left in the cervical cavity for 20 hours. A fortnight after the last application the fornices were much more supple and the cervix had diminished in size, and I was able to operate. I performed total abdominal hysterectomy with extensive resection of the vaginal wall on March 25th, 1909, under good conditions. The patient recovered and remained in good health for a year. Then recurrence took place." Of the five remaining specimens two showed complete absence of cancer in the uterus, vagina, and the broad ligaments. In the other three the absence of cancer in the cervix contrasted with the persistence of a focus in the body of the uterus near the isthmus. The possibility of such foci, which in consequence of their distance cannot be influenced by radium, shows that apparent cure of cancer of the cervix by radium must not be relied upon, but that as soon as the case becomes operable hysterectomy should be performed.

PLAGUE IN THE UNITED PROVINCES.

FROM a report on plague administration in the United Provinces of India for the year ending June 30th, 1911, we regret to learn that a very severe recrudescence of the disease has taken place: 314,495 deaths have been returned, a greater number than in any previous year except 1904–05. This is most disheartening in view of the great efforts that have been made to cope with the spread of the disease. Colonel C. C. Manifold, I.M.S., calls attention to two points of interest which are worthy of note, as in the present state of knowledge regarding its epidemiology any facts accurately recorded require to be borne in mind for future guidance. One point is that, although during the 12 months under review more than twice as many deaths occurred as in the 12 months immediately preceding, the mortality from July to October was less than in the corresponding period of the previous year. The explanation suggested is that the severe epidemic of January to May, 1910, may have killed off so many rats that they could not breed up to their usual numbers before October. The second point is that the two severe epidemics of the present and preceding years followed on good harvests, while 1908–09, in which less than 14,000 deaths occurred, was a famine year. The number of rats depends directly on the quantity of food available; within a few months they will "breed up to the food-supply." It is also noted that severe epidemics follow on early and heavy winter rains, leading to increased humidity of the air and a greater number of rat fleas. As to the progress of the epidemic, the deaths rose from 157 in July to 1231 in October and to a maximum of 94,739 in March, falling rapidly to 921 in June. The death-rate from plague for the whole province was 7·23 per 1000; for the towns it was 12·90; for the districts 6·80. The incidence was very unequal, Muzuffarnagar district suffering the most, with a mortality of 31 per 1000, while Dehra Dun, a few miles off, had no cases at all. The small town of Shikarpur had the highest death-rate—120·7; the large cities suffered very much less—e.g., Lucknow, 6·17; Benares, 10·86; and Allahabad, 1·60. It seems clear that the important factors in determining the severity of an epidemic are local. Large numbers of rats were destroyed, but Colonel Manifold states that experience has shown the absolute impossibility of carrying out rat destruction as a general measure, partly because of the expense, and partly because, after a number have been destroyed, the remainder will speedily breed up again in presence of abundant food-supply. In some districts the people refuse to set traps, as they look upon the rat as a friend who gives the first signal of danger, and "by the sacrifice of his own life gives timely warning of the advance of plague." A satisfactory feature is the increase in inoculations—91,065, compared with 76,120 in the previous year; also a great decrease in the deaths of the inoculated, only 83 compared with 442. The chief objection to the operation, which has to be submitted to yearly, is the recurring inconvenience. Evacuation of infected villages, the inhabitants camping out in the open air or in grass huts, is the favourite means of escaping from the disease, and is most efficacious. On the other hand, very little use is made of plague hospitals. Disinfection and railway inspection are assiduously carried out. Five special officers are now employed in the United Provinces to combat plague, Captain H. Ross, I.M.S., being chief plague officer. All possible precautions will be taken against the spread of plague along the lines of communication leading to Delhi. It must be admitted that the authorities of these provinces have a very arduous and responsible task before them in view of the approaching Coronation Durbar.

EMBRYOS OF THE TRICHINA SPIRALIS IN THE BLOOD IN TRICHINOSIS.

IN 1909 two American writers, Herrick and Janeway, announced that they had demonstrated the embryos of the trichina spiralis in the blood of a patient suffering from trichinosis. The discovery was a logical sequence to Staübli's experimental work on the mode of dissemination of the embryos in the guinea-pig. As an aid to the diagnosis its importance is obvious. In the *American Journal of the Medical Sciences* for September Dr. Albert R. Lamb states that at the Presbyterian Hospital, New York, he investigated four cases of trichinosis with reference to the presence of embryos in the blood and found them in two. From the other two several specimens of blood were thoroughly searched with negative result. In one of these cases the existence of trichinosis was proved by the demonstration of the parasites in the muscles; in the other the diagnosis was never definitely settled. The following are the positive cases: A man, aged 29 years, was admitted with a history of malaise and chilliness for nine days. Four days before admission he took to bed with general muscular pains and swelling of the face and hands. His brother was taken ill at the same time, and they both had eaten pork cooked by themselves a short time before the onset. Examination showed only a fine punctate rash over the abdomen, thorax, and arms. For three days the temperature was about 103° F., and then it gradually fell to normal. A blood count showed 10,000 leucocytes, of which 11·5 per cent. were eosinophile. A blood culture was sterile, but from it four embryos were obtained. In the other case an Italian, aged 20 years, was admitted complaining of backache and general malaise for five days and indefinite pains in the bones and joints for three days. At times he suffered from colicky pains. There were slight puffiness of the eyelids and cheeks, a coated tongue, palpable spleen, and a few fine reddish punctate

spots over the abdomen and chest. There was no muscular tenderness. The temperature was 104° and gradually fell to normal in a few days. The blood counts showed leucocytes varying from 12,000 to 15,600, and eosinophiles rising in a week from 3 to 14 per cent. A blood culture taken on admission was sterile; one embryo was recovered from it. Staübli's original method was used, the only modification being that the blood was obtained from the routine blood cultures made at the hospital, 10 cubic centimetres of blood being divided between two Erlenmeyer's flasks of meat infusion broth. After the culture had been reported sterile the clear supernatant broth was decanted and 10 volumes of 3 per cent. acetic acid was added to the sediment. The mixture was thoroughly shaken and centrifuged and the supernatant fluid was poured off. If the resultant sediment was too thick the laking with the acid was continued until a sediment was obtained in which the search was unhampered by numerous blood cells. A drop of the sediment was poured on a large slide and examined under a low power. The embryos appear as cylindrical slightly curved worms with a refractile outline and characteristic granular structure. The anterior end is a little narrower than the rest of the body and ends in a clear homogeneous cap. Foreign substances in the sediment, such as cotton fibres and fungus growths, may cause confusion, but when once seen the embryos are characteristic. In the present case they measured from 0·1225 to 0·1295 millimetre in length. In the few cases which have been recorded the earliest time at which the embryos have been found was on the seventh day of the disease and the latest the twenty-third.

THE PRIVY COUNCIL, THE CENTRAL MIDWIVES BOARD, AND THE ENFIELD MEDICO-ETHICAL SOCIETY.

THE question of the payment of the medical practitioner who is summoned on the advice of a midwife to attend a case in which under the rules for her guidance she is compelled to "advise that a registered medical practitioner be sent for" was recently raised again by the Enfield Medico-Ethical Society in the letter referred to in a report of the proceedings of the Central Midwives Board in THE LANCET of Oct. 21st, p. 1171. Reference to that report will show that the Enfield Medico-Ethical Society informed a midwife that the society had agreed that a midwife calling in a medical practitioner in any stage of a confinement "must guarantee a fee of not less than a guinea and a half and that the case be taken over entirely by the doctor." This letter appears to have been based upon a not uncommon misconception of the midwife's position and duties in the matter. She does not call in a medical man and is not required by the rules which govern her conduct to do so. She is, however, required in certain cases to decline to attend alone and *to advise that a medical practitioner be sent for*, and she is also required to supply the medical man who is so sent for with a document in a prescribed form reporting to him the conditions on account of which medical assistance is required. It is, perhaps, due to this document that her powers and duties are so often misunderstood. It is unfortunate and it is unjust to the medical profession, and also to midwives, that a position should have thus been thrust upon them by the Midwives Act which has inevitably led to difficulties. The position, moreover, is fraught with danger to the patient, whom the midwife must "cease to attend alone." The difficulty, of course, arises out of the fact that the patient has already engaged a midwife, who has absorbed in many cases all that is likely to be forthcoming in the way of a fee, and that (if he be paid at all) the medical man, who is only summoned to difficult cases, is expected to treat them at the same rate that he would charge when taking normal cases as well as those involving heavy responsibility. The remedy, however, must for the present consist in the obtaining of such payments as boards of guardians may decide to make (as they have power to do) in such matters, and in keeping the dissatisfaction of the medical profession before the Legislature whenever the occasion arises. As to the precise legal value of a guarantee obtained from a midwife in the manner proposed by the Enfield Medico-Ethical Society, we believe that its enforcement in a court of law would have been fraught with difficulty. If not so enforceable it would clearly have been useless.

SCLERODERMIA WITH SUBCUTANEOUS CALCAREOUS CONCRETIONS.

IN the September number of the *British Journal of Dermatology* a case of much interest is described by Dr. R. E. Scholefield and Dr. F. Parkes Weber. There exists a group of cases, characterised by the association of sclerodermia, especially of the fingers, with multiple small calcareous nodules, which have sometimes been mistaken for gouty deposits, but which on analysis have been found to consist mainly of calcium carbonate with some calcium phosphate. The disease progresses very slowly, and at first it is confined to the fingers and toes. The calcification appears to be secondary to the sclerosis, and it is largely dependent on degenerative and obliterative changes in the small blood-vessels. The case described in the article was that of a woman 50 years of age who had suffered from chilblains as a child. Later her fingers often went white, and from the age of 35 years the skin and soft parts of the fingers had been gradually becoming harder and stiffer, and from time to time indolent painful ulcers had formed at the finger-tips. When seen the ends of the fingers had the characteristic appearance of sclerodactylia, and that calcification was present was shown by X rays and by excision. The calcification was most marked on the palmar aspect of the terminal phalanges of the fingers, especially of the left hand. The feet appeared to be quite normal. Excellent skiagrams of the hands accompany the article. Apparently no previous case of this disease has been observed in this country. The literature of the subject has been recently collected by G. Thibierge and R. J. Weissenbach in the *Annales de Dermatologie*, 1911, p. 129.

VETERINARY TRAINING AND THE PUBLIC HEALTH SERVICE.

THE vast extension of the domain of pathology in recent years has brought into clear relief the intimate relationship between human and veterinary medicine. Particularly has the new science—bacteriology—contributed to this, not only by making plain the practical identity of many disease processes in the animal and the human being, and rendering possible the study of the one through the other, but also by demonstrating hitherto unsuspected channels of infection. As a consequence of this new science, exacting as it does considerable technical training and the command of adequate laboratory facilities, a specially trained set of medical practitioners has arisen adequately equipped to examine the problems of public health and preventive medicine. When investigating defects in human habitation, clothing, food, and occupation, they are necessarily driven to a consideration of matters affecting the domestic animals that come into relation therewith in various ways. The problem of tuberculous cattle, for instance, is closely interwoven with that of human tuberculosis. The need is continually becoming more obvious, therefore, for a class of veterinary sanitarians, highly trained in scientific research methods, to approach from the animal side the solution of those common problems that are already being vigorously

attacked from the human side by the medical officers of health. This need recently received forcible expression at the hands of the President of the Faculty of Physicians and Surgeons of Glasgow, Dr. David N. Knox, in his address at the opening of the Glasgow Veterinary College. After pointing out that no gulf existed between human and veterinary medicine, for both were based on the same scientific principles and threw light each upon the other, he urged upon the governors of the College, the veterinary profession, and the students the importance of the study of bacteriology. Referring to a feeling that seemed to be growing in the veterinary profession that veterinarians should be appointed meat and milk inspectors, he said that scientific laboratories were an absolute necessity for efficient inspection, and he proposed that there should be evolved a class of veterinary surgeons especially skilled and capable of working in such laboratories. For some time to come he feared that such officials would for the most part have to be sought among medical officers of health, until the veterinary profession awoke to the necessity of providing the scientific training required. Failing the establishment of a veterinary diploma in public health by the Royal College of Veterinary Surgeons, he offered as an alternative suggestion the establishment by the Glasgow Veterinary College of post-graduate courses in public health, which would involve the establishment of a public health laboratory, where special instruction in chemistry and bacteriology might be given with a practical examination at the end of the course. It seems certain that an increasing scientific equipment of veterinary sanitarians would secure valuable coöperation between the medical and veterinary professions in the field of public health.

Dr. Graham Steell will deliver the Bradshaw lecture before the Royal College of Physicians of London, on Intrathoracic Tumours and Aneurysms regarded from the Clinical Standpoint, at the College, on Thursday, Nov. 2nd, at 5 o'clock.

THE fourth Norman Kerr lecture of the Society for the Study of Inebriety will be delivered by Professor G. Sims Woodhead, M.D., professor of pathology in the University of Cambridge, on Tuesday, Nov. 14th, at 5 P.M., in the lecture theatre of the Pathological Department, Medical Schools, Downing-street, Cambridge. The subject will be the Action of Alcohol on Body Temperature and on the Heart, illustrated by diagrams and lantern slides.

MEDICAL MAYOR.—Mr. Hugh Stott, M.R.C.S. Eng., L.R.C.P. Lond., has accepted the unanimous invitation of the Lewes town council to be mayor of the Sussex county town in the coming year.

SUCCESSFUL ACTION BY A MEDICAL MAN IN DEVONSHIRE.—At the Axminster county court on Oct. 17th and 18th, before his honour Judge Beresford and a jury, an action was brought by Dr. E. Tonge of Beer against a resident of Seaton for 15 guineas for professional services rendered to the defendant's child. There was a counter-claim against Dr. Tonge for £24 for damages for alleged want of reasonable medical care in his treatment of the child. The medical man who attended the child after Dr. Tonge had withdrawn from the case, in giving evidence stated in cross-examination that Dr. Tonge's diagnosis might have been perfectly accurate. After hearing this statement Mr. J. E. M. Dummett, defendant's counsel, said that the case would not be further proceeded with, for if they had thought such evidence possible the case would never have been gone on with. His honour remarked that Mr. Dummett had only acted in a way they expected a member of an honourable profession to act, and directed the jury to give a verdict for Dr. Tonge on claim and counter-claim, and he entered judgment for him with special costs.

THE POSITION OF THE MEDICAL PRACTITIONER UNDER THE NATIONAL INSURANCE SCHEME OF GERMANY.

(FROM A CORRESPONDENT.)

THERE have been published in THE LANCET during the past 12 months more than one article dealing with different phases of national insurance in Germany, and in these articles the comparative conditions prevailing in England and Germany have been dealt with as different points have arisen in discussing Mr. Lloyd George's Bill. But in view of the fact that the German example continues to be quoted by responsible speakers as though it held good in all cases for England, I venture to send you a detailed picture of the position of the medical practitioner under the National Insurance Scheme of Germany.

Position of Workers in England and Other Countries.

Over a century has passed since the first Bill designed to safeguard the health of the factory worker was enforced, when England not only set an example to other nations, but inaugurated a new era of social legislation. Great Britain has reason to be proud of the measures provided for the benefit of her industrial workers, and in this respect she still stands pre-eminent, for it may be safely asserted that in no other country is such care taken to safeguard the worker's health and welfare in the performance of his daily task.

Hitherto, attention has been directed more especially to the conditions under which the work in our great hives of industry is conducted; and if other countries, while following British example, have forestalled British politics by including measures designed to make provision for the worker during sickness and incapacity, it must be remembered that in those countries the introduction of compulsory insurance on the mutual system has been made imperative in the interests of the community at large. No country possesses so effective a system on the whole—and with full recollection of its defaults—for the relief of the poor as is to be found in the British Poor-law; while the voluntary and humanitarian institutions created in Great Britain to provide against any diminution in the wage-earner's capacity for work have for many years included within their sphere of activity a relatively considerable proportion of the entire army of industrial workers and have reached a degree of efficiency unapproached in any other country. This fact speaks highly for the thrift and good sense of the British working man. Twenty-five years ago, when Germany introduced compulsory insurance against sickness, the organisations of this kind then in existence in that country could be treated as a *quantité négligeable*; to-day, when Great Britain is about to follow suit, her Friendly Societies are a factor of paramount importance to the success of the scheme.

Comparison of British and German Measures.

Attention has already been drawn in your columns to the fact that the National Insurance Bill differs in many essential particulars from the German measure (see in particular THE LANCET, Sept. 30th, 1911, p. 956), but a detailed consideration of the points at variance will be opportune. Of particular importance to the medical profession is a consideration of the position of the medical practitioner under the German system, the more so since the Bill of the British Chancellor as it now stands shows the same disregard for the interests of the profession as is unfortunately the case in Germany. Moreover, owing to the absence in Great Britain of certain provisions in existence in Germany, the British practitioner will be placed at a greater disadvantage than his German *confrère*, so that there is every reason to study carefully the conditions under which the medical benefits are administered in Germany, in order to profit in time by the bitter experience gained by Continental colleagues. This course is all the more justified since this very subject offers numerous parallels in both countries, even to the extent that the framers of the British Bill appear intent on duplicating the mistakes made in Germany with regard to the position of the medical man in the working of the scheme, with results that are well known to all who have followed the course of events in Germany.

Scope of National Insurance Bill.

The National Insurance Bill includes within the scope of a single measure two distinct branches of industrial insurance—viz., provision during sickness and invalidity assurance. The insured are either to become members of an "approved" society or will be enrolled as Post Office contributors. Although the income limit for compulsory insurance is fixed at £160 per annum, employers and employees will be called upon to pay a uniform contribution, irrespective of the actual salary earned by the insured (except in the case of persons earning under 2*s.* 6*d.* a day, where the employer will be called upon to make good the difference). In addition to the contributions levied from both parties the State will participate financially in the working of the scheme. The insured will be entitled to receive free medical attendance and free medicine during sickness, as well as sick pay amounting to 10*s.* a week during the first 13 weeks, and 5*s.* during the remaining 13 weeks. Like the contributions, the sick pay will not be affected by the wage-earner's actual salary, only in the case of women and minors a lower scale of pay than the above will be granted. The invalidity benefit is fixed at the uniform rate of 5*s.* weekly. That, I think, is a fair summary of the British scheme. Now look at the German scheme.

The German Scheme.

In Germany insurance against sickness and invalidity form two distinct branches, each administered on totally different lines. The income limit for compulsory insurance is £100, and the administration of the sickness benefits provided in the statutes is entrusted to autonomous sick clubs, mostly of a local character. In smaller places a communal sick club embraces all the insured residing within its limits; in larger towns separate sick clubs are formed to include all the workers engaged in a particular trades or crafts. In addition to these organisations, industrial establishments employing at least 50 hands are empowered to form their own clubs for the benefit of their employees. All these sick clubs are entirely self-governing—that is to say, the management is vested in a board of which one-third of the members are representatives of the employers, and the remaining two-thirds of the employees. The State merely reserves to itself the right of supervision, and demands that every club shall possess a reserve fund amounting to an average year's expenses, based on the expenditure of the three preceding years.

As far as the existing Friendly Societies and similar voluntary institutions are concerned, the German law does not interfere in their activity, and as long as they provide their members with the minimum benefits required by the insurance measures, membership of one of these organisations excuses the worker from re-insuring in any other kind of compulsory club. The contributions levied depend upon the wage-earner's salary, and the total amount may not exceed 6 per cent. of his wages. Of this, one-third is paid by the employer and the other two-thirds by the employee; the State does not contribute towards the cost of sickness insurance. The sick pay, too, varies with the worker's salary and legally may not be less than half his usual wage throughout the entire period of 26 weeks, and should the insured undergo treatment in a hospital his dependents are entitled to receive an allowance amounting to half of the sum the breadwinner would be drawing were he to be treated in his own home.

Invalidity insurance is a separate measure with which is included provision for old age. The administration of this branch of social reform differs totally from that adopted in the case of sickness insurance, inasmuch as it is controlled by the State. It forms the subject of a special contribution which employer and employee alike have to pay, this time in equal shares, in addition to the sums levied for sickness insurance. Here, too, the contributions are graded according to the worker's salary, and the invalidity pension to which he is entitled varies with the length of time that he has been insured and with the wage class to which he belongs. In this case the State assumes a portion of the cost of administration and supplements every pension paid out of the funds of the scheme by an annual grant of £2 10*s.* The old age pensions, which become operative at the age of 70, are also subject to the same system of calculation.

Concrete Examples.

A concrete example will best illustrate the difference in the position of the insured under both schemes. The British worker earning 5*s.* a day will be called upon to pay a weekly contribution of 4*d.*, his employer 3*d.*, and the State will add 2*d.*; in all 9*d.* Assuming that the same man goes over to Germany and is insured in a sick club levying a rate of 2½ per cent., with the same salary he will have to pay 6*d.* and his employer 3*d.*, or 9*d.* for both. In addition to this employer and workman each will have to pay a weekly sum of 2¼*d.* towards insurance against invalidity and old age, so that the workman earning 30*s.* a week would, under these circumstances, pay in all for industrial insurance in Germany 8¼*d.*, and his employer 5¼*d.* weekly, or 4¼*d.* and 2¼*d.* more respectively than they will be called upon to pay in Great Britain. Of course, the fact must not be overlooked that in England old age pensions are not contributory, whereas in Germany provision to this end is included in the insurance against invalidity. Further, in England the workman during sickness will receive 10*s.*, and after 13 weeks 5*s.* as sick pay, and the latter amount in the case of invalidity. In Germany, on the contrary, he is entitled to a uniform sick pay of at least 15*s.* a week, and were he forced to go to a hospital his dependents would receive a weekly allowance of 7*s.* 6*d.* Sex and age are not allowed to influence the German rate of sickness benefit. As regards invalidity pensions, it may be mentioned that the lowest figure is £5 16*s.* per annum, and the highest may be given as about £22 10*s.*; as already stated, the sum paid out depends upon the insured person's wage class and the length of time that he has been insured. Old-age pensions range from £5 10*s.* to £11 10*s.*

It is evident from a consideration of the above examples that the German workman pays proportionately more than the British wage-earner will be called upon to contribute. The total contributions for both forms of insurance in Germany amount to 42*s.* 7*d.* per person insured, this figure representing an average weekly charge of 6*d.* on the workman's salary, and a little more than 3¾*d.* weekly to be paid by the employer. Insurance against accidents, as it is non-contributory for the workers, has not been taken into consideration; it has no bearing on the points under discussion.

Position of Medical Man under German Scheme.

Let us now consider the position of the medical practitioner under the German scheme. The insurance laws, otherwise replete with detail, contain no provisions for regulating the remuneration of the medical men whose duty it is to give effect to the medical benefits to which the insured are entitled. This is a most unfortunate omission, and the same mistake is apparently to be repeated in Great Britain. In Germany, however, there are no Health Committees to sanction contracts entered into between doctors and sick clubs, and all arrangements between both parties are made directly, without the intervention of any outside body. The practitioner who assumes the position of club doctor does so by private agreement with the board of the club, and the contract is not subject to ratification by any other person. At the present moment the average rate of remuneration of club doctors amounts to 4*s.* per head of the insured, and in the case of clubs which extend free medical treatment to the member's family the honorarium is about 12*s.* The question of free choice of doctor is usually regulated on the following basis: if the club has arrangements with a number of medical practitioners the insured are called upon annually to select a doctor from the list, and a change of doctor during the course of the same illness is not allowed. For the treatment of the insured living at some distance from the residence of the usual club doctors an arrangement is made whereby the services of the nearest practitioner alone will be available should occasion arise, a very wise provision which saves many a doctor from wasting his time in visiting patients residing at some distance.

With regard to the methods of remuneration in vogue, it is a matter for congratulation to note that the system of paying the club doctor a fixed annual salary in return for indefinite and practically unlimited calls upon his services is gradually dying out. In clubs where the members select their medical attendant for the coming year the total number in each case is multiplied by the *per capita* grant and the amount paid out in full to each doctor, who thus receives a remuneration proportionate in a way to the potential work he may be called upon to perform. Other clubs hand over the total sum provided for medical attendance to the local medical society, and the latter undertakes to divide the amount

among the several club doctors. This is usually done by means of points; each doctor attributes a certain number of points to every case attended, and the whole is examined by a committee of the society which fixes the relative value of the services rendered and divides the money accordingly. Several clubs, however, pay the doctor for each case he attends, payment being based on a scale of fees established in the medical tariff, and this system of remuneration is naturally the fairest to both parties.

Duties of Club Doctors.

A few excerpts from a sick club doctor's contract will best illustrate his duties. He is enjoined not to lose sight of the interests of the club while attending to its members, and to guard against malingerers; sufferers from anæmia, particularly females, are not to be declared unfit for work unless this is really the case. The doctors are at liberty to attend all meetings of the board, and it is requested that they should consult the board with regard to serious cases of illness. Patients who wish to see the doctor in their own home must inform him of their desire before 8 A.M. during the summer months and 8 30 A.M. in winter. Patients who are able to go out should visit the doctor during his consultation hours. Suspected malingerers are to be sent at once to an hospital, also all infectious cases, as well as all patients who are not able to receive adequate care in their own home, or where a speedier recovery seems likely to result from treatment in the hospital. If the doctor thinks it necessary to prescribe for a member expensive articles, such as wine, brandy, special foods, or special treatment (e.g., massage, baths), the consent of the board must first be obtained. As far as possible only inexpensive drugs should be used in prescribing. For the remuneration granted the doctor agrees to attend by day or night to the members of the club, to apply plaster bandages, suture wounds, and perform small operations. For night visits in urgent cases to patients residing outside the doctor's place of abode the latter in some clubs receives a special fee of 3*s*. If the club doctor is prevented from attending to his professional duties for any cause he must provide a substitute at his own cost. For assistance at a birth he receives 10*s*.

Medical Tariff.

It will be seen from the above that the contract club doctor is only called upon to perform what may be termed routine work, and here we come to one of the great differences between the German and the British scheme. In both countries the insured are considered entitled to the best medical attendance, but in the British Bill no mention is made of any provision for major operations, &c. In Germany every sick club makes arrangements with a number of specialists—for instance, with an oculist, a specialist for internal complaints, for diseases of the ear, and of the throat and nose. If the club doctor considers it advisable for a patient to receive special advice or treatment he informs the board, which then gives the member a form authorising him to consult one of the specialists in question. The remuneration of the specialist's work is based on the minimum fees set forth in the official scale of charges for professional services. This is a medical tariff which establishes a maximum and minimum fee for every kind of medical or surgical service, and in the absence of any agreement between patient aud doctor with regard to the latter's fee its provisions become operative. Its minimum charges are applicable in all cases where the cost of treatment is borne by the public funds, including the sick clubs. The figures below give the minimum fees only in illustration of the rate of remuneration for such work done on behalf of the insured (Prussian scale):—

Removal of foreign body from the larynx or œsophagus ...	6*s*.
Removal of nasal polypus	10*s*.
Resection of a joint	30*s*.
Operation for empyema	20*s*.
Operation for phimosis	6*s*.
Removal of foreign body from the cornea	3*s*.
Iridectomy	20*s*.
Removal of the eyeball	30*s*.
Curettage of the uterine cavity	10*s*.

In connexion with the above it may be here mentioned that in distinction to Great Britain, where the hospitals are dependent upon voluntary contributions for their maintenance, these institutions in Germany are either under the control of the municipality or of the State. Each hospital has a regular scale of charges, graded to suit various purses, and those undergoing treatment have to pay accordingly. In the case of sick club patients the lowest rates are usually charged. The accommodation in the hospitals is divided into three classes. First-class patients each have a room to themselves with one bed, and residents in the locality pay 6*s*. a day, non-residents 8*s*. In the case of acute infectious diseases these charges are raised to 8*s*. and 10*s*. respectively. Attendance at a birth is charged at least £2 10*s*. in this class. In the second class each room contains two or three beds, and the daily charges here amount to 3*s*. and 4*s*., or for infectious cases 4*s*. and 6*s*. for residents and non-residents respectively; confinements at least 30*s*. These charges are in force in the town hospital of the capital of one of the German Grand Duchies. In addition to these charges, patients in both classes have to pay 1*s*. a day for medical attendance, while dressings, medicines, wines, special forms of treatment (e.g., X rays), and washing of the body-linen are charged for extra. The third-class patients, which include members of sick clubs, pay at the rate of 2*s*. a day, and the fee for attendance at a birth is here fixed at 12*s*. In this class no extra charge for medicines or operations is made, except, of course, in the case of private patients who, if known to have means, may be called upon to pay. The fees are fixed by the director of the hospital, and in the case of first- and second-class patients who are residents of the town a sum equal to a fortnight's stay may be demanded in advance as security; in the case of non-residents this amount may be doubled to cover a month's treatment. It is apparent that German hospitals take no risks in dealing with well-to-do patients, a singular contrast with British hospital conditions. The third-class patients include all those whose treatment is paid for out of the public funds or by sick clubs, and the respective bodies are simply debited with the amount incurred. The whole is on a sound business footing and the hospital is run in the same manner as any other form of municipal enterprise.

Relations between Doctors and Clubs in Germany.

A few words on the relations between doctors and clubs may be of interest. It is the endeavour of the latter to keep down expenses for medical treatment and for medicines to as low a level as possible in order to provide the members with other forms of benefits, mostly taking the form of a higher rate of sick pay. For this reason the doctor is obliged to prescribe as cheaply as possible, and there are in existence in Germany several collections of formulæ which are supplied to club doctors for use when prescribing for patients. Thus in liniments olive oil is not to be used, instead some cheaper oil, rape-seed oil for instance, has to be prescribed. Expensive forms of dispensing are tabooed, such as infusions, divided powders, and pills. Some clubs go so far as practically to forbid solutions: to quote an instance, the doctor is required to prescribe half an ounce of potassium iodide with instructions to the patient to dissolve it in a wine-bottle full of water and to take a glassful as a dose. Instead, again, of prescribing, say, 10 powders, each containing 8 grains of phenacetin, the doctor writes out a prescription for 80 grains of this drug, with directions to "take as much as will go on the point of a knife." This course has been severely condemned, while the new Hungarian Pharmacopœia shows that the dangers which may arise from this loose form of dosage are fully recognised by forbidding the dispensing of all potent drugs in bulk.

As soon as a patient presents himself for treatment the doctor must make a report to the board of the club, informing it of the nature of the member's illness, and on the form he must state whether the patient has received permission to go out, and if so, the hours fixed by the doctor must be given. Every week the doctor has to make a report to the club, and when the patient is discharged as fit for work the exact date must be communicated to the board. If the doctor has reason to believe that he is dealing with a malingerer or is of opinion that hospital treatment would be advisable under the circumstances, he informs the board, and the latter takes the necessary steps to have the person admitted to hospital. If some special treatment appears indicated—for instance, massage, a course of baths, or a mineral-water cure—the consent of the club must first be obtained, and the extent to which such treatment is accorded depends naturally upon the financial position of the club.

Some organisations are able to send their members to such well-known resorts as Baden-Baden or Bad Nauheim to undergo treatment, or convalescents are sent to recuperate in some country place or sanatorium, several of which have been erected by the sick clubs in coöperation for the sole benefit of their members.

Invalidity Pensions.

The method in force in Germany with regard to applications for invalidity pensions are not without interest. The sick clubs have to make provision for their members for a period of 26 weeks, and at the end of this time, if the insured is still incapacitated for work, the benefits extended under the invalidity insurance now become operative. The insured must make an application to the invalidity insurance office, and in addition a medical certificate must be presented, for filling up which the doctor receives a fee of 5*s*. The information required is certainly exhaustive, this being partly due to the fact that an invalidity pension is only paid out if the applicant's capacity for work has been reduced to one-third of the normal, otherwise the authorities are empowered to make the person undergo a special form of treatment intended to restore him to complete health—this includes admission to a sanatorium for tuberculosis. In this certificate the doctor has to answer questions dealing with the following: complaints made by the applicant; commencement, duration, and course of the affections which have led to incapacity; duration of the last treatment by the doctor giving this certificate; objective examination—viz., constitution, appearance, bodily condition as regards strength and nutrition, pulse; nervous system; heart and blood-vessels; respiratory organs (circumference of chest in expiration and inspiration); organs of the abdomen (hernia); organs of sense; urinary and sexual apparatus; limbs; possible alcoholism; ultimate diagnosis. In addition the doctor must make statements as to the following: origin of the applicant's complaint and his degree of incapacity for work. Further, he must express an opinion as to whether the incapacity is likely to be permanent or whether a suitable form of treatment is indicated in order to improve the patient's earning powers or his condition of health. The last question on the form is, Do you suspect the applicant of exaggerating or malingering?

The Question of Dispensing.

A few words on an innovation, as far as Great Britain is concerned, which will follow the introduction of the National Insurance Bill may prove of interest here. It is proposed in great measure to divorce the doctor's duty of giving professional advice from dispensing, and the supply of medicine to the insured is to be handed over with few exceptions to the pharmacist. In Great Britain the public is accustomed to associate the tangible result of the doctor's visit with the professional advice given; both have grown to form a twin result of "calling in the doctor." This is to be changed under the new *régime*, and the bottle of medicine will no longer be bound up so intimately with the doctor's visit owing to the intervention of another party. It is an old custom which Great Britain shares alone with some Swiss cantons and the United States; elsewhere the doctor is strictly forbidden to dispense, and the compounding of all medicines is a privilege reserved to the pharmacist. In Great Britain the man with a registrable pharmaceutical qualification can open a pharmacy without further difficulty, and this condition prevails in the Latin countries, in Holland, and in Switzerland. In Germany, Austria-Hungary, Scandinavia, Russia, and the Balkan States the number of pharmacies is limited in proportion to the population, there being on an average one pharmacy for every 10,000 inhabitants. The exercise of the profession of pharmacy is treated in the light of a monopoly, and the authorities reserve to themselves the right of granting permission to open or conduct a pharmacy to suitable applicants. Under these circumstances it is easy to understand the great difference in the profession in Great Britain and abroad, and if the British pharmacist deals in numerous articles which his Teuton *confrère* is apt to consider beneath the dignity of a skilled profession to handle, it must be remembered that the conditions are totally different. Abroad the revenue of the pharmaceutical chemist, who is a university man, is largely derived from dispensing, which is far from being the case in British pharmacies, with the exception of certain businesses in the West End of London and a few quarters in great cities. However, in return for his privileged position the German pharmacist is hedged in by laws and regulations of the most drastic kind, and is under constant Government supervision—his pharmacy is inspected by the authorities from time to time in no perfunctory manner, and any slight transgression is recorded against the owner, with dire consequences at some later date.

Scale of Charges for Dispensing.

In these countries there exists another provision absent in Great Britain, but which, it appears, will have to be created to meet the requirements of the Insurance Bill. In those countries in which the exercise of pharmacy is subject to restriction, and also in Italy, there exists an authoritative scale of charges for dispensing, and for rich and poor alike the cost of a prescription is identical, severe penalties being inflicted in the case of any overcharge. These dispensing tariffs are elaborated by the Government authorities, the cost of a prescription being obtained by adding the charge for the ingredients, a charge for the manipulations entailed in compounding, and the charge for the container. Three prescriptions "taxed" according to the German tariff will illustrate this point:—

		s.	*d.*
1.	Potass. bromid., ʒii....	0	1
	Potass. iodid., ʒii.	0	8
	Aq. ad ℥vi.	0	4½*
	"Dispensation" (i.e., label, cork, registration) ...	0	2
	Bottle	0	2
	Cost of above prescription	1	5½

* Charge for solution, including water.

2.	Tinct. opii, ʒii.	0	4
	"Dispensation"	0	2
	Patent drop bottle	0	3
	Cost of above prescription	0	9
3.	Quinin. sulph., gr. jss.	0	1½
	Acetanilid., gr. x.	0	1
	Mitte pulv. xii.		
	Charge for mixing	0	2½
	Charge for dividing into 12 powders...	0	7½
	"Dispensation"	0	2
	Cardboard box	0	2½
	Cost of above prescription	1	5

In the case of prescriptions for members of sick clubs most countries compel the pharmacist to grant a rebate (in Germany of 10 to 15 per cent.) off the charges of the official tariff; with few exceptions, due to differences of a local character, a member of a sick club can have his prescription made up in any pharmacy should there be more than one available in his place of residence. Indeed, the fact that one-fifth of the entire population of the German empire is insured is sufficient to prove that a very large proportion of the prescriptions now dispensed must belong to the class of club work. For reasons of economy the club patients are required to bring back the bottle or container in the event of having a prescription repeated, and the use of expensive pots or glass-stoppered bottles is forbidden, unless specially prescribed by the doctor.

Results of Capitation System.

It has been claimed for the National Insurance Bill that its introduction will tend to regulate the doctor's financial position by relieving him of the burden of unpaid bills, by the vast extension of the capitation system. From German experience it would seem that capitation payments are not in accordance with modern views of the relation between the work accomplished and the remuneration provided, and a system of this kind seems bound to prove unfair to one of the participants. The introduction of compulsory insurance in Germany was followed by a great increase in the number of medical students, and the competition among members of the profession was turned to advantage by the sick clubs. It must be remembered that in Germany the selling of practices is totally unknown, and partnerships in private practice do not exist, and a practice in that country does not represent capital as is the case in England. Soon the doctors discovered the mistake they had made, and recognising the futility of individual action they combined

to form a powerful organisation, known as the "Leipziger Verband"; its full title is the "Association of German Doctors for the Protection of their Economic Interests," and it now has a membership of over 23,000. The strikes of club doctors in Cologne and elsewhere are well known, and show that the association has not hesitated to adopt extreme measures in order to promote the material position of its members.

German Statistics.

In conclusion, some interesting figures from the official German statistics may be adduced to show the work entailed in practice by a scheme of national insurance. While the health of the empire has materially improved during the past quarter of a century, we are confronted by the peculiar fact that the volume of work accomplished in connexion with compulsory insurance has considerably increased, and incidentally the expenditure has assumed enormous proportions. In 1909 the average cost for medical attendance per head of the insured amounted to 5*s*. 9*d*.; this represents an increase of no less than 165·1 per cent. since 1885. Hospital treatment accounted for 3*s*. 4*d*. per insured, an increase of 122 per cent. since 1892, while the cost of medicines and appliances amounted to 3*s*. 7*d*., an increase of 110·1 per cent. since 1885. It is interesting to note that the total expenditure per member in Germany amounts to 12*s* 8*d*. for medical benefits. If we deduct two-thirds from the 3*s* 4*d*. for hospital treatment, and consider the remaining 1*s*. 1*d*. as covering the cost of medical attendance (the figure accepted in Germany), this would mean that the actual cost of medical attendance per person insured amounts to 6*s*. 10*d*. No less than 40·3 per cent. of the insured were reported unfit for work during 1909; this represents an incidence of illness amounting to 42·2 per cent. among the males, and to 35·2 per cent. among the females. The average length of each case of illness, coupled with incapacity, amounted to 20·5 days, or 19·4 days in the case of males, and 23·8 days among the females. Per head of the insured this represents an average of 8·25 days' illness. These figures also show an increase in the course of the past 25 years.

GENERAL MEDICAL COUNCIL.

ELECTION OF DIRECT REPRESENTATIVES.

NOMINATIONS for candidates for the four vacancies, three for England and one for Scotland, on the General Medical Council must reach the Council Office at 299, Oxford-street, London, W., or, in the case of Scotland, 54, George-square, Edinburgh, by Nov. 1st. The candidates for the posts of Direct Representatives for England are, we understand, at present as follows: Dr. H. W. Langley Browne of West Bromwich, Dr. H. A. Latimer of Swansea (who both seek re-election), and Mr. T. Jenner Verrall of Bath, who are standing jointly as the three candidates recommended by the British Medical Association; Mr. George Brown of Callington, Cornwall, Dr. Sidney C. Lawrence of Lower Edmonton, and Dr. Arthur Hawkyard of Leeds, who are also standing jointly, and whose election address appears below; Mr. George Jackson of Plymouth; and Dr. Arthur Haydon of London.

Dr. Norman Walker of Edinburgh seeks re-election as the Direct Representative for Scotland, as was stated in our Scottish letter of last week.

To the Registered Medical Practitioners of England and Wales.

LADIES AND GENTLEMEN,—We have been invited by the Society of Members of the Royal College of Surgeons of England and the Imperial Medical Reform Union to allow ourselves to be nominated as candidates for the three vacant posts as Direct Representatives for England and Wales on the General Medical Council. These requests have been supported by so many practitioners that we have decided to accept their invitations. One of us (George Brown) has already served ten years on the Council, and his record of hard work there on your behalf is well known to you all.

In supporting our candidature you make an emphatic protest against the attempt now being made by the officials of the British Medical Association to seize upon all the four positions and fill them, not with representatives of the practitioners directly elected by them, but with nominees of the Council of the Association. If this attempt were successful the composition of the General Medical Council would revert to that prior to the Act of 1886—viz., an assembly of guardians of vested interests, and so opposed to the interests of "the rank and file." It is intolerable and unjust this endeavour to limit the candidature entirely to those men who hold office in the Association as long as there are others able and willing to represent the practitioners and independent of official trammels and whose course of action will be based on actual experience of your needs and whose policy is plainly defined by the terms of this address.

We three are standing on one and the same platform, which has amongst its stout planks: (1) suppression of quackery and imposture; (2) reform of the General Medical Council with an increase of its legal powers; (3) the one-portal system of examinations for qualification to practise our profession (read the leading article in THE LANCET of Oct. 21st, 1911); and (4) checking of the abuse of free hospital treatment.

With reference to No. 2, we think that the time has arrived for a thorough revision of the constitution of the General Medical Council. Consideration of its proceedings for ten years past will convince anyone that it is quite time our profession was governed by a council, the majority (at least) of whose members should be men elected by the practitioners of the United Kingdom and Ireland, and not by a council consisting of representatives of the teaching and examining bodies and of nominees of the Crown. These gentlemen have never been engaged in general practice and know little or nothing whatever of the difficulties that beset "the family doctor" or of the causes of our inadequate incomes, and those only obtained by excess of work.

The National Insurance Bill.—We think that the General Medical Council should have taken a more active part in safeguarding the interests of the profession which are so seriously threatened by this Bill promoted by Mr. Lloyd George, the Chancellor of the Exchequer. If you send us by your votes to the medical Parliament we intend to carefully watch all proposed legislation which appears likely to affect your interests, and to urge the Council, when it is necessary, to take prompt and effective action on your behalf. If the present legal powers of the Council are not equal to its work, then no time should be lost in acquiring further powers. We consider that the activity of the Council should extend far beyond the regulation of the studies and the registration of students after their approval by one or more of the numerous licensing bodies, whose interest in your welfare disappears as soon as they have pocketed their last fees and handed you a legal qualification to practise. We are in sympathy with the "good intentions" of the National Insurance Bill, but whilst giving the British Medical Association every credit for its efforts in this matter we are well aware that many of you think that in their conferences with the Chancellor of the Exchequer the necessity of a low wage-limit and an adequate capitation fee (and their definition in the Act itself) should have been insisted on. Further, Mr. Lloyd George might have been urged to seriously consider the alternative to a capitation fee of payment for work done. Failing recognition of the just claims of the practitioners, we consider that the proper course is to withdraw the Bill from Parliament or at least the clauses relating to medical attendance. We are convinced that the Bill, as it stands, will do us all great harm. In this direction the influence of the General Medical Council should be at once brought to bear on the Government.

Ourselves.—Our residential qualifications are excellent, for we live respectively in the South-West, North, and South-East of England. Whilst one (George Brown) has personal acquaintance with the conditions of practice in the South and West, following years of general practice in central London, another (Hawkyard) has the same experience of the North of England, and the third one (Lawrence) has a thorough knowledge of the conditions of practice in the Midland counties and London suburbs. We claim to be well qualified to represent you on the Council by reason of a very large united experience of medical work, both of a public and private character, and from a preventive as well

as a curative point of view. We thoroughly understand the evils of club and pauper practice from personal experience, which gives us an intimate knowledge of the requirements of "the man in practice."

On these grounds, and in view of our avowed policy, we confidently ask for your own votes and for your influence in securing other votes for

Your obedient servants,

GEORGE BROWN,
Hon. Sec. of the Imperial Medical Reform Union; formerly Direct Representative; Vice-President of the Society of M.R.C.S. Eng.

ARTHUR HAWKYARD,
President of the Leeds and District Medical Practitioners' Association.

SIDNEY C. LAWRENCE,
Hon. Sec. of the Society of M.R.C.S. Eng.; M.O.H. of Edmonton.

Oct. 24th, 1911.

To the Editor of THE LANCET.

SIR,—I have decided to become a candidate for election as a Direct Representative in order to promote the interests of English and colonial graduates holding foreign degrees.

It has been my endeavour for many years past to overcome insular prejudice and bring about a much needed reform—namely, the registration of foreign degrees—as an indication of academical distinction and evidence of study abroad. From a financial point of view this would bring more than £1000 into the treasury of the General Medical Council.

My address to the electors on this and other matters will be found in the current issue of THE LANCET and the *British Medical Journal*.

I am, Sir, yours faithfully,

ARTHUR GEORGE HAYDON, M.D.,
Secretary, Brussels Medical Graduates' Association.

Cavendish-square, London, W., Oct. 24th, 1911.

MALARIA IN BOMBAY.

IN April of the present year Dr. Charles A. Bentley, who has been employed on special duty in Bombay in connexion with malaria investigation, presented a report on his researches, which has now been published. In our issue of Sept. 2nd (p. 732) we noted the action of the Bombay Government consequent on this report; and on Sept. 23rd (p. 924) we reported the discussion that took place thereon by the City Corporation. Dr. Bentley's investigation was exhaustive, and his report offers several points of interest for discussion

Nature of Population.

In regard to the population involved, which numbered 977,822 at the Census in 1906, he shows that it was altogether abnormal; not only are the inhabitants of Bombay composed of very many different races—as many as 62 different dialects being spoken—but, in addition to the fixed and permanent population, there are three categories of "floating population"—viz., temporary residents for business purposes; a labouring class, shifting regularly according to the season of the year; and a very large number of travellers and pilgrims constantly arriving and departing. The vast majority of the inhabitants belong to the labouring class, and of these a very large number exist in conditions of the greatest poverty, one of the chief consequences being excessive overcrowding—as many as 22 persons have been counted asleep on the floor and adjoining verandah of a single-room tenement. In addition to the poverty so widely prevailing under normal conditions, during the last few years the increased prices of grain have considerably added to the difficulty of the struggle for existence.

In the earlier part of the last century Bombay had a rather good, but vague, reputation for health, owing to its sea breezes, though it is doubtful if this was deserved; malaria must have been present, but was not particularly prevalent. In 1903 Powell found the malaria parasite in 2542 out of 3413 blood specimens from the police. In 1905 the municipal corporation resolved that, in view of the increasing prevalence of, and high mortality from, fevers, a comprehensive inquiry should be instituted; nothing, however, of much importance was done until an investigation by Major Liston, I.M.S., in 1908, showed that in a particular area near the new docks 80 per cent. of the children had enlarged spleens, and 50 per cent. of those examined harboured malarial parasites in their blood. In November of that year the Bombay Government decided to undertake a systematic research into the whole matter of malarial causation and prevention; of this the present report by Dr. Bentley is the result.

Estimation of Malarial Prevalence.

The first point to be determined was the actual extent of malarial prevalence; this was effected (1) by making a census of enlarged spleens; and (2) by a systematic series of blood examinations for the parasite. As a result of a house-to-house "spleen census," by examining 52,536 children in different parts of the city, McKendrick found that in Ward A, the most southerly portion of the Bombay peninsula, extending from Colaba to the new docks and marine lines, the percentage with enlarged spleens was 29·9; in Ward B, adjoining Ward A to the north on the harbour side, the percentage was 13; while in no other ward was the percentage above 5·9; and in F and G, the two northernmost ones, it was only 1·1 and 1·0 respectively. The percentage for the whole city was 7·2, a figure which has, however, little significance, as the numbers examined in the various areas were not in proportional relation with the respective child populations. In Ward A, where spleen enlargement was found most frequently, approximately 80 per cent. of the children were examined; in Wards D to G, where the spleen enlargement was slight, less than 40 per cent. were examined; therefore, although 7·2 per cent. of the total number examined had enlarged spleens, the real incidence in the city was considerably less. Even on this incomplete examination the incidence is not high, and, as the author of the report states, Bombay is not, as a whole, very malarious. In certain ward-sections, however, the percentage was found to be much higher—e.g., 42·3 in Esplanade section (A Ward), 37·8 in Mandvi Section (B Ward), and 33 in North Fort (A Ward): though the prevalence in the two former may be associated with proximity to the New Dock Extension Works, this explanation will not hold good for the whole of the North Fort Section. In a part of this, and in Dhobi Talao Section on the west of the city, a large amount of malaria is due to mosquitoes breeding in the wells of private houses.

The second mode of examination for malaria—viz., search for parasites in the blood—confirmed the conclusions arrived at by the spleen census. The parasite index (percentage of infection) was found to be 37·5 in Esplanade Section, 34·9 in North Fort, and 40·8 in Dhobi Talao Section. The index was high in nearly all the other sections of A, B, and C Wards in the south and west of the island, while in the four other wards to the north the rate was much lower, in nearly all cases below 5 per cent. Dr. Bentley considers that it is hopeless to attempt to draw any conclusion as to the prevalence of malaria in different years, owing to the confused nomenclature adopted in the death returns, in which ague and remittent fever are returned as separate headings from malaria. He quotes the remarkable statement in the official *Bombay Gazeteer* that "Tarwadi and Byculla have a very low death-rate from malaria, but are notorious for the prevalence of ague and remittent fever"; this is as nice a "derangement of epitaphs" as Mrs. Malaprop herself could have produced.

Causation.

As to the causation of epidemic malaria in Bombay in recent times, Dr. Bentley is decidedly of opinion that the construction works of the Alexandra and Hughes Docks, commenced in 1904 and still in progress, have been largely responsible, by acting as a centre from which diffusion took place. In Mandvi section, for instance, which lies to the west of Victoria Dock, the disease penetrated some distance; and further west, about half-way through Chakla section, its progress being then barred by the high blocks of dwellings in the narrow streets of that neighbourhood. In some cases an enlarged spleen rate of 20 per cent. was found in residents on the side facing the harbour, while in tenements facing in the opposite direction the spleen rate was only 3 per cent. So also the railway staff resident near the Victoria terminus and on the side next the docks suffered severely (so much so that as many as ten trains had to be cancelled). On the P. and O. boats lying in the southerly berths of the Victoria Docks many cases of malaria occurred in 1908, but only among members of the crew who remained on board; ships lying out in the harbour were not affected. It was found, however, that this infection from the dock site would not

account for all the malarial incidence; in North Fort, in Dhobi Talao section on the west side of the island, and elsewhere, extensive incidence of malaria exists, due to the presence of open house wells, which form innumerable breeding places for the mosquito. The principal agent in transmission is considered to have been Neocellia stephensi. The sequence of events that caused the outbreak appears to have been as follows: (1) Existence of serious malarial infection in residents of North Fort near to the new dock works; (2) numerous open house wells, tanks, and cisterns in North Fort adjoining this area; (3) settling down of coolie labourers in temporary huts on the new dock site; (4) formation of pools of water in the vicinity; (5) gradual spread of Neocellia stephensi from North Fort to these new breeding places; (6) spread among the labourers; and (7) the occurrence in 1907–08 of climatic, economic, and other conditions favouring the outbreak. It is pointed out that the settling of large numbers of coolies in temporary huts on the site of their work was a contravention of the rule laid down by Colin more than 50 years since, and emphasised by Fayrer, that labourers should not be housed on the site of large excavation works, but should be removed from the locality.

Preventive Measures.

The measures that have been taken to combat the epidemic have been chiefly directed to the extermination of the mosquitoes concerned, by treatment of small pools and wells with pesterine—i.e., crude petroleum; by the covering of all open wells, tanks, and cisterns, and the draining and filling in of these wherever feasible; and by the free distribution of quinine daily in sugar-coated tablets. The systematic and thorough inspection and protection of wells, both in and near houses, and of tanks and cisterns, are the measures regarded as of most importance. Some amount of success has already attended the efforts that have been made. The discovery by Major Liston that Neocellia stephensi was the carrier responsible for most of the infection made it possible to concentrate preventive measures against this species; infected individuals were not met with before the middle of July, either in 1909 or 1910. The commonest anopheline mosquito in Bombay is Nyssomyzomyia rossi, but no instances of malarial infection of this species were discovered. Dr. Bentley points out in conclusion that, as eradication of malaria is the end to be achieved, permanent measures for the protection or abolition of the breeding places of malaria carriers must have precedence, though at the present time in places like the new dock works special temporary measures will be required; quinine administration is subordinate, but not to be neglected. He estimates the cost at rather more than a lakh of rupees, or about £7000, per annum, while the present money loss from sickness and death due to malaria he calculates at about twelve times this amount.

We have only touched on a few points in the report of this inquiry, which appears to have been conducted in the most painstaking and exhaustive manner; it indicates with precision on what lines action should be taken, and it is to be hoped that sanitary administrations throughout India will be prompted also to take action, on lines similar to, though not necessarily the same as, those so forcibly recommended by Dr. Bentley.

THE LONDON COUNTY COUNCIL AND MEDICAL AFFAIRS.

Annual Report of the Education Medical Officer.

DISCUSSION took place at the meeting of the Education Committee of the London County Council on Oct. 25th on the annual report for 1910 of the medical officer of the education service (Dr. Kerr). The report will be issued shortly, but in the meantime the general purposes subcommittee presented a summary of the document, which, it said, had been subjected to much examination and criticism on account of the increase in cost of medical work in the schools. Naturally this increased work had necessitated the augmentation of the medical staff. Beginning with 40 quarter-time doctors in 1908, this staff had been increased to 56 on Sept 1st, 1909, and to 72 on Sept. 1st, 1910. The professional staff employed at the end of 1910 numbered 84 doctors (70 men and 14 women), giving time equivalent to the full time of 24 medical officers. As from Jan. 1st, 1911, this staff had been further increased to 114 doctors (96 men and 18 women), giving time equivalent to the full time of 32 medical officers. The permanent staff at the end of 1910 comprised the medical officer (education), two assistant medical officers (full-time), two assistant medical officers (half-time), seven assistant medical officers (quarter-time), including specialists in mental, ophthalmic, aural, orthopædic, and dental work, together with 72 medical inspectors (quarter-time). This staff had been increased as from Jan. 1st, 1911, by two assistant medical officers (full time) and 28 medical inspectors (quarter-time).

As the Council's arrangements made four years ago for carrying out the statutory duties imposed by the Education (Administrative Provisions) Act, 1907, had now fully developed, and medical inspection was completely organised in all the schools, it was anticipated that the staff at present engaged would be sufficient to cope with the work.

Of the children examined in full detail there were recorded in last year's report (1909) the results of 37,420 examinations, with 12,656, or 33 per cent., requiring medical treatment. These represented children at all ages. Of the 172,619 children examined in 1910 and noted in detail, 52,954, or 32·6 per cent., received advice cards. The proportion of children who would be selected by the doctors after careful examination and given advice cards could now be fixed on the basis of the last two years as 65,610 out of 210,039, which is 32 per cent., or approximately one-third of those examined. Of the 172,619 children recorded, 81,151 were returned as normal—i.e., free from any definite organic defect. Bad defects of vision or eye diseases were recorded in 18,923. Defects of throat or nose numbered 29,927; of ears or hearing, 9499; skin disease, 2913. This included 453 ringworm cases found by the medical officers, ringworm being generally excluded by the nurses; other diseases were recorded in 15,296.

With regard to the state of nutrition of individual children, those recorded as in good condition were 46·7 per cent., those in moderate condition 41·8 per cent., and those in bad condition 11·5 per cent. The physique of the children had been made the subject of considerable research, the results of which were presented in the form of charts. The various groups shown on the charts corresponded very closely with the three classes distinguished by the British Association. The correspondence of the result with the predominant occupation of the parents in each area was, with a few exceptions, remarkably close. The lower averages were found in the riverside districts, North Kensington, and in a central area extending from the Strand district to Bow and Bromley. The most unexpected figure was the weight recorded for Fulham, and here the majority of the children were tidy and came from apparently comfortable homes of the artisan and commercial class. The committee pointed out that the numbers at present available were, perhaps, too small and liable to error from exceptional children.

During the year under review some beginnings were made with the provision of dental treatment for children, but so little had the public realised the value of this service that its development must be slow. Medical inspection was now carried out in all the Council's secondary schools, training colleges, trade and technical schools. It was just as important in these institutions as in the elementary schools, and, from the economical point of view, probably more important. Each student was examined once a year, and each institution visited once in six weeks. Great difficulties were still experienced in the provision of proper educational treatment of epileptics, neither was there at present any special accommodation for children who were both mentally and physically defective. In 1910 there was a striking diminution in the incidence of scarlet fever and diphtheria. Measles, on the contrary, had been unusually prevalent, the figures both for the spring and autumn showing an abnormal rate of incidence for the time of the year.

In the course of a short discussion Mr. A. J. Shepheard referred to Dr. Kerr's complete report as a most interesting survey of one phase of the social life of London. Both Mr. Shepheard and Miss Adler, a subsequent speaker, urged the importance of making the Council's arrangements for medical treatment more complete.

The report was ordered to be placed on sale.

The Propagation of the Unfit.

The Asylums Committee in a report to the London County Council on Oct. 24th mentioned the case of a female patient,

aged 67 years, who was admitted to Colney Hatch Asylum on Sept. 12th, 1911, for the sixteenth time since April, 1872. The patient had also been in other asylums on eleven occasions. She was married at 18 years of age, and had had 13 children, five of whom were dead. Her first attack of insanity was at the age of 21, when her first child was born. The patient's children were said to be all healthy with the exception of two, who had recently shown signs of insanity. She had two aunts in asylums, and two of her sisters had suffered from insanity; both were dead, one having committed suicide. The committee submitted these particulars by way of supplementing the history of a male patient given some time ago.[1] It seemed a striking illustration of the need for legislation to prevent the increase of the unfit.

Deportation of Alien Pauper Lunatics.

The Asylums Committee also reported as to the proceedings taken under the Aliens Act, 1905, with a view to deporting to their own countries foreign lunatics chargeable to London ratepayers. The number of certificates granted by stipendiary magistrates since the Act came into operation was 86, and 59 patients had been deported. This left 27 to be accounted for, and as to these the Home Secretary did not see his way to make an expulsion order in 14 cases, four died before the expulsion order was issued, one case was removed to a private institution, and eight cases were still under consideration by the Home Secretary. In addition 12 patients had been deported without a certificate being necessary. The total number deported to date was 71.

London Asylum Accounts.

The district auditor reported on the accounts of the London county asylums for the year ended March 31st, 1911. The total expenditure of the committee was £620,249. the cost of maintenance of the ten asylums varying from £70,061 in the case of Claybury to £11,544 in the case of the Epileptic Colony. The expenditure on maintenance showed an increase of £17,157 on the figures of the previous year; this was due chiefly to the higher cost of provisions and necessaries. The auditor gave definite figures on this point. Provisions in the year ended March, 1910, cost £173,422; in 1911, £184,263. an increase of £10 841. Necessaries in 1910 cost £60,482, and in 1911 £63,412, an increase of £2930.

Dr. Geoffery Clarke, second assistant medical officer at Long Grove Asylum, has been appointed first assistant medical officer at Colney Hatch Asylum.

Dr. J. J. Murphy has resigned his appointment as first assistant medical officer at Banstead Asylum in order to go abroad, and the committee has received the resignation with regret.

MEDICINE AND THE LAW.

A House Surgeon's Claim under the Workmen's Compensation Act.

IN the Court of Appeal recently an appeal was heard in which the house surgeon of the Kidderminster Infirmary appealed against the decision of the county court judge who had refused to award him compensation under the Workmen's Compensation Act. The circumstances in which he had claimed were as follows. Subscribers had purchased for the infirmary an X ray apparatus. The house surgeon had voluntarily offered his arm for the purpose of experiment to test the length of exposure to the rays, and having sustained a burn, applied for compensation to the infirmary committee. The county court judge held that it was no part of the applicant's duties to expose himself to the risk of such an experiment, and that consequently the accident did not arise out of and in the course of his employment, and refused to award compensation. The Court of Appeal, after hearing the arguments of counsel on behalf of the appellant, did not call upon the defendants' counsel to reply, and dismissed the appeal with costs, holding that it was no part of a house surgeon's duties to submit himself to dangerous experiments, and confirming the decision of the county court judge that the accident did not arise out of and in the course of the appellant's employment.

[1] THE LANCET, April 8th, 1911, p. 961.

An Action for the Recovery of Fees.

In the Chertsey county court recently Dr. S. G. Tippett sued Sir Joseph B. Robinson, claiming £84 19*s.* for fees for professional attendance alleged by the plaintiff to have been rendered at the request of the defendant to a woman who had been injured in a collision between his motor-car and the cart in which she was riding. The defendant denied that he had employed the plaintiff to attend the woman or authorised his employment. According to Dr. Tippett's evidence the services which he rendered, including the engagement of two nurses, were authorised on behalf of the defendant by Lady Robinson, with whom he communicated by telephone after he had been called to attend the patient at the time of the accident. He was aware that a sum of money had been paid to the injured woman in respect of the accident. Sir J. B. Robinson denied having given any authority for the engagement of the plaintiff in connexion with the case, or that he had ever admitted liability for the accident. He stated that he had paid 14 guineas for the nurses engaged as an act of charity to the injured woman. Lady Robinson denied having authorised the indefinite engagement of nurses, and further denied that she had agreed to pay the plaintiff's charges, and also that she had any authority to pledge her husband's credit. The defendant's chauffeur denied having engaged the services of a medical man, and stated that nothing had been said at the time of the accident as to the defendant being responsible for the expenses to be incurred. A verdict for the plaintiff for £50 was returned, leave to appeal being granted.

Juries and Sympathy in Cases of Infanticide.

Some not unneeded observations were made by Mr. Justice Scrutton to a jury at the Old Bailey recently when summing-up the evidence in a case in which a young married woman, 25 years of age, was being tried for the manslaughter of her infant son. There was evidence that the prisoner had suffered from depression. His lordship reminded the jury that they must not allow their sympathies to interfere with their giving true answers to questions of fact, and informed them that he had in his list for trial four cases arising out of the deaths of infants immediately after their birth. He pointed out that the effect of leniency on the part of juries in response to appeals to their sympathies must ultimately be an increase in the number of babies killed immediately after birth "in order to get them out of the way," adding, "your business is to answer questions of fact according to the facts and not in accordance with your sympathies. The question of punishment is for the court, and I ask you to do me the justice to believe, although I have a red robe and a wig, that I am a man, with exactly the same feelings and sympathies as yourselves; and for the punishment you must trust the judge." The extent to which infants are killed or allowed to die at birth because it is desired that they should be "out of the way" is probably more fully realised by the medical profession than by the public at large, and has long been a subject of protest by them. The woman who is placed in the dock to answer a charge of killing her child finds it easy to excite sympathy, and sometimes obtains it more readily than if want, or whatever the predisposing cause may be, had led her to commit an illegal act of a different character. On the other hand, it is not denied that a woman situated as the prisoner was in the case under comment may be legitimately an object of profound pity. In short, to put an end to the life of a human being is an act demanding full investigation and careful consideration to determine the degree of criminality involved. Mr. Justice Scrutton eventually recognised the claim to clemency of the prisoner before him, after the jury had convicted her, by passing upon her a sentence of five days' imprisonment, which implied her immediate release; but the jury equally rightly affirmed that a crime had been committed. The tendency of juries to assume the right to exercise clemency, which is for the judge in his discretion and with his fuller knowledge and experience, was illustrated in two instances at this trial. The grand jury had thrown out the indictment for murder, although, as the judge observed, they had received no recommendation from the court to do so, and although the prisoner had admitted having given her child three teaspoonfuls of laudanum and having then drunk the remainder of the drug in her possession, facts which rendered it at least probable that she intended to kill him and herself

as well. Secondly, at the close of the case the jury which tried it at first returned as their verdict that the prisoner was guilty, but was not responsible for her actions. The effect of this, as was pointed out to them by the judge, would have been to consign her to a criminal lunatic asylum, but the finding of irresponsibility was withdrawn at his lordship's suggestion and a recommendation to mercy substituted, with the result stated above.

The Absence of a House Surgeon from an Inquest.

At an inquest at Doncaster recently comment was made by the coroner, and a rider was appended to their verdict by the jury censuring the house surgeon of the infirmary who had failed to attend as a witness. The deceased had died in the infirmary after meeting with an accident, and a medical man who had seen him when he was under treatment was able to give evidence as to the cause of death. The inquest was held at 5 P.M., and in the course of the afternoon the house surgeon had communicated with the coroner by telephone, and had told him that he had made arrangements for going away that afternoon. The house surgeon had also mentioned the name of the medical practitioner who could, and who in fact did, give evidence with regard to the case. The house surgeon had been told by the coroner that he must attend as a witness unless the substitute whom he mentioned could give evidence that would be sufficient, but he had not been formally summoned. In the circumstances it is difficult to see why the house surgeon should be made the object of censure in his absence, and without any opportunity being given to him to explain; and it may be added that if he had foregone his plans, whatever they may have been, and attended, he would not as a member of the staff of a hospital have been entitled to the ordinary fee of a medical witness.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 77 of the largest English towns, having an estimated population of 16,157,797 persons in the middle of this year, 7574 births and 4450 deaths were registered during the week ending Oct. 21st. The annual rate of mortality in these towns, which had steadily decreased from 21·2 to 14·9 in the eight preceding weeks, further declined to 14·4 per 1000 in the week under notice. During the first three weeks of the current quarter the mean annual death-rate in these towns averaged 14·8 per 1000, and was 0·1 per 1000 below the annual death-rate during the same period in London. The death-rates in the 77 towns last week ranged from 6·8 in Hornsey, 7·0 in Grimsby, 8·3 in Coventry, and 9·6 in Merthyr Tydfil to 21·5 in Dewsbury, 21·6 in Bootle, 22.2 in Bury, and 22·7 in Sunderland. The 4450 deaths from all causes in the 77 towns were 183 fewer than the number in the previous week, and included 406 which were referred to the principal epidemic diseases, against numbers decreasing from 2900 to 512 in the eight preceding weeks. Of these 406 deaths, 223 resulted from infantile diarrhœa, 60 from diphtheria, 48 from enteric fever, 37 from measles, 25 from whooping-cough, and 13 from scarlet fever, but not one from small-pox. The mean annual death-rate from these epidemic diseases last week was equal to 1·3 per 1000, against 2·6 and 1·7 in the two preceding weeks. The deaths of infants under 2 years of age attributed to diarrhœa, which had steadily decreased from 2714 to 357 in the eight preceding weeks, further declined to 223 last week, and caused the highest annual death-rates of 2·2 in Bootle, in St. Helens, and in Warrington, and 2·5 in York. The deaths referred to diphtheria, which had averaged 45 in the three preceding weeks, rose to 60 last week, and included 18 in London, 4 in Portsmouth, and 3 in Liverpool. The fatal cases of enteric fever, which had been 35, 37, and 39 in the three preceding weeks, further rose last week to 48, which was the highest number recorded in any week of the current year; 10 deaths were recorded in Hull, 8 in London, 4 in Bradford, and 3 in Stoke-on-Trent. The deaths attributed to measles, which had been 19, 18, and 27 in the three preceding weeks, rose again last week to 37; 13 deaths occurred in London, 8 in Wolverhampton, 3 in Nottingham, and 3 in Salford. The deaths referred to whooping-cough, which had been 51, 55, and 35 in the three preceding weeks, further decreased to 25 last week, and included 4 in Birmingham, 3 in London, 3 in Cardiff, and 2 in Sunderland. The 13 fatal cases of scarlet fever were 3 in excess of the number in the previous week, and included 2 in Liverpool. The number of scarlet fever patients under treatment in the Metropolitan Asylums and in the London Fever Hospital, which had steadily increased from 1327 to 1966 in the seven preceding weeks, had further advanced to 2106 on Saturday last; 344 new cases of this disease were admitted to these hospitals during the week, against 333, 293, and 355 in the three preceding weeks. These hospitals also contained on Saturday last 1099 cases of diphtheria, 206 of whooping-cough, 178 of enteric fever, and 82 of measles, but not one of small-pox. The 1239 deaths from all causes in London last week were 94 less than the number in the previous week, and included 228 which were referred to diseases of the respiratory system, against numbers steadily rising from 73 to 210 in the seven preceding weeks. The deaths attributed to different forms of violence in the 77 towns, which had increased from 134 to 170 in the three previous weeks, declined to 150 last week, and 346 inquest cases were registered. The causes of 39, or 0·9 per cent., of the deaths registered in the 77 towns during the week under notice were not certified either by a registered medical practitioner or by a coroner after inquest. All the causes of death were duly certified in Sheffield, Leeds, Bristol, West Ham, Bradford, Newcastle-on-Tyne, Nottingham, Salford, and in 52 other smaller towns. The 39 uncertified causes of death last week included 10 in Birmingham, 9 in Liverpool, and 2 each in Portsmouth, Leicester, St. Helens, Hull, and Gateshead.

HEALTH OF SCOTCH TOWNS.

In eight of the principal Scotch towns, having an estimated population of 1,710,291 persons in the middle of this year, 891 births and 513 deaths were registered during the week ending Oct. 21st. The annual rate of mortality in these towns, which had been 14·9 and 16·4 per 1000 in the two preceding weeks, declined to 15·7 in the week under notice. During the first three weeks of the current quarter the mean annual death-rate in these Scotch towns averaged 15·7 per 1000, and was 0·9 per 1000 above the mean death-rate during the same period in the large English towns. The annual death-rates in the Scotch towns last week ranged from 11·6 and 14·0 in Perth and in Edinburgh to 16·8 in Leith and 17·0 in Glasgow. The 513 deaths from all causes in the eight towns were 25 less than the number in the previous week, and included 47 which were referred to the principal epidemic diseases, against 60 and 74 in the two preceding weeks; of these 47 deaths, 20 resulted from diarrhœa, 9 from measles, 7 from scarlet fever, 5 from diphtheria, 5 from whooping-cough, and 1 from enteric fever, but not one from small-pox. The mean annual death-rate from these epidemic diseases in the eight towns last week was equal to 1·4 per 1000, and was 0·1 per 1000 above the mean death-rate from the same diseases in the 77 large English towns. The deaths attributed to diarrhœal diseases, which had been 52, 33, and 41 in the three preceding weeks, declined to 20 last week, and included 17 of infants under two years of age; 9 deaths were registered in Glasgow, 5 in Dundee, and 3 in Edinburgh. The deaths referred to measles, which had been 1, 4, and 5 in the three previous weeks, further rose last week to 9, and comprised 7 in Glasgow and 2 in Aberdeen. The 7 fatal cases of scarlet fever were 1 below the number returned in each of the two preceding weeks, and included 2 each in Glasgow, Aberdeen, and Greenock. The deaths attributed to diphtheria, which had been 13, 11, and 12 in the three preceding weeks, declined to 5 last week, of which 2 were recorded in Glasgow. The 5 deaths referred to whooping-cough were equal to the average in the two preceding weeks, and included 3 in Glasgow. The fatal case of enteric fever occurred in Glasgow. The deaths referred to diseases of the respiratory system, which had steadily risen from 41 to 80 in the five preceding weeks, declined to 78 last week, and were 2 below the number returned in the corresponding week of last year. Of the 513 deaths from all causes in the eight towns last week, 182, or 35 per cent., were recorded in public institutions, and 27 deaths were attributed to different

forms of violence. The causes of 12, or 2·3 per cent., of the deaths in the eight towns last week were not certified; in the 77 English towns the proportion of uncertified causes last week did not exceed 0·9 per cent.

HEALTH OF IRISH TOWNS.

In the 22 town districts of Ireland, having an estimated population of 1,149,495 persons in the middle of this year, 540 births and 409 deaths were registered during the week ending Oct. 21st. The annual rate of mortality in these towns, which had been 19·6 and 19·3 in the two preceding weeks, declined to 18·6 per 1000 in the week under notice. During the first three weeks of the current quarter the mean annual death-rate in these Irish towns averaged 19·2 per 1000; in the 77 English towns the mean annual death-rate during the same period did not exceed 14·8 per 1000, while in the eight Scotch towns it was equal to 15·7. The annual death-rate last week was equal to 20·0 in Dublin (against 14·3 in London), 17·0 in Belfast, 26·5 in Cork, 8·9 in Londonderry, 20·4 in Limerick, and 26 6 in Waterford; in the 16 smallest of these Irish towns the mean annual death-rate did not exceed 15·7 per 1000. The 409 deaths from all causes were 16 less than the number returned in the previous week, and included 47 which were referred to the principal epidemic diseases, against 81 and 74 in the two preceding weeks; of these 47 deaths, 31 resulted from diarrhœa, 4 from enteric fever, 4 from scarlet fever, 3 from measles, 2 from whooping-cough, 2 from diphtheria, and 1 from typhus, but not one from small-pox. These 47 deaths from the principal epidemic diseases were equal to an annual death-rate of 2·1 per 1000. The mean rate from the same diseases in the 77 English towns last week was equal to 1·3, while in the eight Scotch towns it did not exceed 1·4 per 1000. The deaths attributed to diarrhœal diseases, which had steadily decreased from 121 to 58 in the five preceding weeks, further declined to 31 last week, all of which were of infants under two years of age; 13 deaths were recorded in Dublin, 9 in Belfast, 2 in Wexford, and 2 in Sligo. The 4 deaths referred to enteric fever were equal to the average in the three preceding weeks, and were all registered in Dublin. The 4 fatal cases of scarlet fever were slightly in excess of recent weekly numbers, and occurred in Dublin. The 3 deaths attributed to measles were also slightly in excess of recent weekly numbers and included 2 in Dublin and 1 in Cork. The 2 deaths referred to whooping-cough were equal to the average in the three preceding weeks, and comprised 1 in Dublin and 1 in Belfast. The 2 fatal cases of diphtheria were recorded in Cork and Dundalk respectively, while that of typhus was registered in Dublin. The deaths referred to diseases of the respiratory system, which had been 64 and 50 in the two preceding weeks, rose to 66 last week. Of the 409 deaths from all causes in the Irish towns last week, 137, or 33 per cent., were recorded in public institutions, and 8 deaths were attributed to different forms of violence. The causes of 14, or 3·4 per cent., of the deaths registered in the 22 towns last week were not certified either by a registered medical practitioner or by a coroner after inquest; the proportion of uncertified causes in the week under notice did not exceed 0·9 per cent. in the 77 large English towns, and was equal to 2·3 per cent. in the eight Scotch towns.

VITAL STATISTICS OF LONDON DURING SEPTEMBER, 1911.

IN the accompanying table will be found summarised complete statistics relating to sickness and mortality in the City of London and in each of the metropolitan boroughs. With regard to the notified cases of infectious diseases, it appears that the number of persons reported to be suffering from one or other of the nine diseases specified in the table was equal to an annual rate of 6·9 per 1000 of the population, estimated at 4,522,628 persons in the middle of the year. In the three preceding months the rates were 4·4, 5·1, and 4·4 per 1000 respectively. The lowest rates last month were recorded in Paddington, Kensington, the City of Westminster, Hampstead, and Holborn; and the highest rates in St. Marylebone, Finsbury, Shoreditch, Bethnal Green, and Deptford. Scarlet fever was much more prevalent than in the preceding month; among the several metropolitan boroughs the greatest proportional prevalence of this disease was recorded in St. Marylebone, Hackney, Shoreditch, Bethnal Green, and Deptford. The number of scarlet fever patients under treatment in the Metropolitan Asylums Hospitals, which had been 1206, 1400, and 1324 at the end of the three preceding months, had risen again to 1656 at the end of last month; the weekly admissions averaged 261, against 162, 200, and 159 in the three preceding months. The prevalence of diphtheria showed a considerable increase over that recorded in the previous month; this disease was proportionally most prevalent in Hampstead, Islington, Finsbury, Bermondsey, Greenwich, and Woolwich. There were 892 diphtheria patients under treatment in the Metropolitan Asylums Hospitals at the end of last month, against 771, 839, and 720 at the end of the three preceding months; the weekly admissions averaged 138, against 102, 120, and 85 in the three preceding months. Enteric fever was very much more prevalent than in any other recent month; the greatest proportional prevalence of this disease was recorded in Hammersmith, Fulham, St. Pancras, Finsbury, the City of London, and Lewisham. The Metropolitan Asylums Hospitals contained 155 enteric fever patients at the end of last month, against 33, 47, and 56 at the end of the three preceding months; the weekly admissions averaged 39, against 6, 9, and 10 in the three preceding months. Erysipelas was proportionally most prevalent in Hackney, Finsbury, Shoreditch, Bethnal Green, Stepney, Southwark, and Deptford. The 18 cases of puerperal fever notified during the month included 4 in Southwark, 3 in Stepney, and 2 each in Hackney and Lewisham. The 19 cases notified as cerebro-spinal meningitis included 4 in St. Pancras, 4 in Battersea, and 2 each in Islington, Hackney, Shoreditch, and Lambeth.

The mortality statistics in the table relate to the deaths of persons actually belonging to the several boroughs, the deaths occurring in institutions having been distributed among the boroughs in which the deceased persons had previously resided; the death-rates from all causes are further corrected for variations in the sex- and age-constitution of the populations of the several boroughs. During the four weeks ending Sept. 30th the deaths of 5537 London residents were registered, equal to an annual rate of 16·8 per 1000 of the population, against 11·7, 12·4, and 18·9 per 1000 in the three preceding months. The death-rates last month ranged from 9·1 in Hampstead, 11·3 in Stoke Newington, 12·9 in Wandsworth and in Lewisham, and 13·1 in Paddington to 20·5 in Finsbury and in Bethnal Green, 21·2 in Southwark, 23·7 in Shoreditch and in Poplar, and 24·0 in Bermondsey. The 5537 deaths from all causes included 24 from measles, 13 from scarlet fever, 46 from diphtheria, 57 from whooping-cough, 27 from enteric fever, and 1369 among children under two years of age from diarrhœa and enteritis. The lowest death-rates from these diseases in the aggregate were recorded last month in the cities of London and Westminster, in Hampstead, Stoke Newington, Hackney, and Holborn; and the highest rates in Shoreditch, Bethnal Green, Poplar, Southwark, Bermondsey, and Deptford. The 24 deaths from measles were 23 below the corrected average number in the corresponding period of the five preceding years; of these 24 deaths, 7 belonged to Southwark, 4 to Bethnal Green, and 4 to Stepney. The 13 fatal cases of scarlet fever showed a decline of 16 from the corrected average number, and included 2 in Fulham, 2 in St. Marylebone, 2 in Islington, and 2 in Southwark. The 46 deaths from diphtheria were slightly below the average number in the corresponding period of the five preceding years; the greatest proportional mortality from this disease was recorded last month in Hammersmith, Hampstead, Islington, Finsbury, and Greenwich. The 57 fatal cases of whooping-cough showed a decline of 7 from the corrected average number; this disease was proportionally most fatal in Stoke Newington, Bethnal Green, Poplar, Bermondsey, Lambeth, Deptford, and Greenwich. The 27 fatal cases of enteric fever were 6 above the corrected average number in the corresponding period of the five preceding years; of these 27 deaths, 5 belonged to Finsbury, 4 to Camberwell, 3 to St. Pancras, and 2 each to Fulham, Islington, Southwark, and Wandsworth. The 1369 deaths from diarrhœa and enteritis among children under two years of age showed a marked decline from the exceptionally high number recorded in August; among the metropolitan boroughs the mortality from this cause was proportionally greatest in Shoreditch, Bethnal Green, Stepney,

ANALYSIS OF SICKNESS AND MORTALITY STATISTICS IN LONDON DURING SEPTEMBER, 1911.

* Including membranous croup. † The death-rates are corrected for variations in sex- and age-constitution of the populations of the several boroughs, the population of England and Wales being taken as the standard. ‡ Deaths from "typhus fever" and "other continued fevers" are not now distinguished in the Registrar-General's weekly returns; these two columns are therefore omitted from the Table.

Poplar, Southwark, Bermondsey, and Deptford. In conclusion, it may be stated that the aggregate mortality in London last month from the principal infectious diseases (excluding diarrhœa) was 19·7 per cent. below the average.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments have been notified:—Staff-Surgeon: R. W. B. Hall to the *Victory*, additional, for disposal. Surgeon: C. C. Macmillan to the *Pegasus*, on commissioning.

ROYAL ARMY MEDICAL CORPS.

Surgeon-General G. D. Bourke, C.B., K.H.P., Principal Medical Officer of the Irish Command, has been appointed a member of the corporation of the Royal Hibernian Military School. Lieutenant-Colonel F. W. G. Gordon-Hall from Glasgow, has embarked on the s.s. *Rohilla* for a tour of service in South China. Lieutenant-Colonel J. C Morgan has on promotion been appointed to the medical charge of the military hospital at Glasgow. Lieutenant-Colonel A. A. Sutton, D S O., has taken up duty as senior medical officer on the West Coast of Africa with the military forces. Lieutenant-Colonel C. J. Macdonald has embarked for a tour of duty in North China. Lieutenant-Colonel R. Kirkpatrick, C.M.G., commanding the Seventh Company of the Royal Army Medical Corps and in medical charge of the Military Hospital at Devonport, has been placed under orders to proceed abroad during the ensuing trooping season. Lieutenant-Colonel W. C. Beevor, C.M.G., commanding the station hospital at Bangalore, has been appointed to the Medical Charge of the transport s.s *Rewa*, leaving Bombay for Southampton. Major A. L. A. Webb has arrived at Sierra Leone for a tour of duty on the West Coast of Africa. An exchange of stations on the foreign service roster has been approved between Major C. R. Evans and Captain J. A. Hartigan; the former has accordingly taken up duty at Malta, and the latter will proceed to North China on the termination of his leave. Major F. M. Parry has been placed under orders for a tour of service at Mauritius during the ensuing trooping season. Major G. St. C. Thom, commanding the station hospital at Subathu, Simla Hills, has been transferred to Murree. Major H. K. Palmer, at present serving at the station hospital, Colaba, Bombay, has been granted six months' leave of absence home from India. Major A. H. Safford, specialist in bacteriology, has been appointed to take charge of the Research Laboratory at Fyzabad. Captain J. H. Graham has been ordered to Ireland for duty, and on arrival will be posted to the Cork District. Captain N. Low, company officer of the Royal Army Medical Corps Detachment at Belfast, has been selected for appointment to the Belfast, University Contingent, Officers Training Corps from Oct. 20th to Nov. 23rd, and Captain H. C. Gray, clinical pathologist at the Royal Infirmary, Phœnix Park, Dublin, has been similarly selected for attachment to the Dublin University (Trinity College) Contingent from Oct. 18th to Nov. 21st. Captain E. W. Powell has taken over charge of the Brigade Research Laboratory at Aden. Captain A. D. Frazer has been instructed by the War Office to join for duty in Ireland, and will be posted to the Belfast District on arrival. Captain R. B. Black, on termination of the promotion course at the Royal Army Medical College, has been appointed to the Egyptian Army with the local rank of Bimbashi. Captain P. G. Hyde, on the closing of Rathmore Camp, has joined at Dublin. Captain R. L. V. Foster and Captain D. S. Skelton, from the Royal Army Medical College, have been posted to Bodmin and York respectively. Captain D. P. Johnstone, from Brackenbir Moor, has been appointed to Manchester. Captain R. K. White has been transferred from Tipperary to Kinsale. Captain J. W. S. Seccombe, in charge of the Cantonment General Hospital at Nasirabad, has been detailed for duty on board the s s. *Rewa*, leaving Bombay for Southampton. Captain A. T. Frost, specialist in dermatology and venereal diseases at the Royal Infirmary, Phœnix Park, Dublin, has been detailed for duty with the Royal College of Surgeons Contingent, Officers Training Corps, from Oct. 18th to Nov. 21st. Captain R. L. Argles, staff surgeon at Ferozopore and in medical charge of the Ordnance Department, has been granted one year's extension of his Indian tour of service by H E. the Commander-in-Chief in India. The following Captains have been selected by the War Office to attend the courses of instruction for promotion to the rank of Major to be held at the Royal Army Medical College, London, commencing on Nov. 1st next: C. J. Thomson (Edinburgh), A. B. Smallman (Woolwich), W. F. Ellis (Bradford), G. H. J. Brown (Rhayader Camp), T. E. Harty (Guildford), D. P. Watson (Preston), G. A. Kempthorne (Glencorse), N. E. Dunkerton (Woolwich), R. T. Collins (Woolwich), A. C. Osburn (Colchester), L. Bousfield (Crownhill), J. H. Douglass (Dublin), R. R. Lewis (Aldershot), A. L. Otway (Belfast), C. H. Turner (Newbridge), and W. F. H. Vaughan (Cosham).

INDIAN MEDICAL SERVICE.

His Excellency the Governor of Bombay in Council has been pleased to appoint Lieutenant-Colonel C. H. L. Meyer to be principal of the Grant Medical College in Bombay in succession to Lieutenant-Colonel H. P. Dimmock, who has retired from the service. Major H. G. Melville, Bengal Presidency, has arrived home on leave of absence from India. Major F. A. Smith has been appointed Agency Surgeon to the Eastern States of Rajputana on his return from leave. Major G. McI. C. Smith has been selected to officiate as Professor of Materia Medica at the Medical College, Lahore, during the absence on leave of Major H G. Melville. Major P. St. C. More has been granted 20 months' combined leave from India. The services of Major C. H. Bowle-Evans, Bengal, have been placed at the disposal of H.E. the Commander-in-Chief in India. Major T. Stoddart has taken up duty as Civil Surgeon at Mogok in succession to Captain H. S. Matson, transferred to be Civil Surgeon at Taunggyri. Major A. Gwyther has been selected for appointment as Civil Surgeon of Howrah during the absence of Lieutenant-Colonel A H. Nott. Captain M. H. Thornely has been transferred from Manbhum to Shahabad as civil surgeon, in succession to Major T. H. Delany. Captain A. C. W. Young has been appointed to hold charge of the Bacteriological Research Laboratory in the Bannu Brigade by His Excellency the Commander-in-Chief in India. Captain W. S. Nealor has taken up duty as medical officer of the 123rd Outram Rifles. Captain K. S. Singh has been granted one month and eleven days' privilege leave of absence. The services of Captain A. P. G. Lorimer have been placed temporarily at the disposal of the Government of Madras. Captain R. H. Bott, specialist in advanced operative surgery to the Fourth (Quetta) Division, has taken up duty as Professor of Midwifery at the Lahore Medical College during the absence on furlough of Major R Heard Captain J. W. Little has been selected by the Foreign Department as agency surgeon to fill the vacancy caused by the transfer of Major C. H. Bowle-Evans. Captain S. H. Bingess has been appointed a Specialist in Advanced Operative Surgery. The services of Captain J. Smalley have been placed temporarily at the disposal of the Government of Bombay. Captain A. H. Proctor has taken up duty as Resident Surgeon at the Medical College Hospital in Calcutta during the absence on leave of Captain E O. Thurston. Captain N E Griswood has been transferred to Delhi as District Plague Medical Officer. Lieutenant R L. Gamlen has left Lahore for Calcutta in medical charge of the 32nd Sikhs *en route* to join the Abor Expeditionary Field Force.

SPECIAL RESERVE OF OFFICERS.

Royal Army Medical Corps.

Captain Ernest U. Bartholomew resigns his commission (dated Oct. 21st, 1911). Lieutenant John Fraser is confirmed in his rank.

TERRITORIAL FORCE.

Infantry.

4th Battalion, The Cheshire Regiment: Surgeon-Captain John B. Yeoman resigns his commission (dated Oct. 21st, 1911).

Royal Army Medical Corps.

3rd West Lancashire Field Ambulance, Royal Army Medical Corps: The undermentioned officers to be Captains (dated Oct. 1st, 1911):—Lieutenant Augustus A.W. Merrick, Lieutenant Ernest Knight, and Lieutenant Norman S. Jeffrey.

1st London (City of London) Field Ambulance, Royal Army Medical Corps: Lieutenant Edward L. Rowse to be Captain (dated Oct. 1st, 1911)

2nd Welsh Field Ambulance, Royal Army Medical Corps:

Arthur Cecil Devereux to be Lieutenant (dated July 11th, 1911).

Attached to Units other than Medical Units.—Lieutenant Frank W. Burn to be Captain (dated July 3rd, 1911). Captain James Andrew resigns his commission (dated Oct. 21st, 1911).

For attachment to Units other than Medical Units.—Lieutenant Henry Robinson, from the London Mounted Brigade Field Ambulance, Royal Army Medical Corps, to be Lieutenant (dated Sept. 21st, 1911).

THE NAVY LEAGUE AND THE PREVENTION OF TUBERCULOSIS.

At the annual meeting of the Navy League, which was held under the presidency of Mr. Geoffrey Drage at the Royal United Service Institution on Oct. 21st, a resolution, proposed by Lady Fremantle, to the effect that the establishment of sanatoriums for consumptive naval invalids is eminently desirable, and that the Navy League undertakes to do everything possible to promote a scheme having this object in view, was adopted.

MEDICAL STORES IN THE PRUSSIAN ARMY.

No. 47 of the Military Medical publications[1] issued by the Prussian War Ministry, has lately reached us. First there is a description of the large storehouse itself, its machinery-installations, and the plan for expanding it in war time. Then the various branches of the work done here are successively detailed. The store department administers the authorised establishment of medical equipment for the Prussian army, and whatever other similar stores may be assigned to it. It distributes stores to the various Prussian army corps as they may require them, equips new depôts when ordered and also those on the lines of communication not supplied by their provincial authorities. When mobilisation is over it takes back stores from those depôts that are to be reduced. It examines new or altered patterns of equipment, communicating its conclusions to the depôts of the other army corps, and, if necessary, to the War Ministries of Bavaria, Saxony, and Würtemberg. It conducts original researches, and tests in its laboratory and workshops all modern improvements in material for the care of the sick, and advises, after discussion with the military hospitals of Berlin, whether these will be of advantage to the army. Finally, it teaches medical officers, informing them of the latest advances in equipment, and how they are to use and care for the patterns issued; it trains medical storekeepers and instructs volunteer "Red Cross" *personnel*, also occasionally foreign officers. On its staff are a lieutenant-colonel of the Army Medical Corps, a senior dispenser, an artificer, and a staff sergeant. First-aid dressings are made here and bandages. In each first-aid packet is a gauze compress and bandage impregnated with sublimate solution (3 per 1000, perhaps to be replaced by cyanide). The bandage is 4 m. by 7 cm. (4½ yards by 2¾ inches). The compress is 18-fold and measures 5 by 2¾ inches. It is sewn on to the bandage, a 10-inch strip being left free to begin with. They are then all rolled up together, according to pattern, wrapped in calico and tied with a thread. Directions for use are printed on a paper affixed with turpentine-starch paste. The date and the order, "To open pull off the thread," are stamped on the outside. These packets are put up in boxes of 300 and are then sterilised, first for an hour at 105° C., and then for two hours following in current steam. A woman can make 100 a day, and some 400,000 or 500,000 are turned out in a year. The silk bought is analysed to make sure its chemical constitution is such as to promise stability; it must be sufficiently inextensible, and its breaking strain must be in due relation to its diameter, which is measured under a microscope. Silk threads are put up in glass tubes having a cotton-wool filter at each end. They are first sterilised, then dried, metal capsules are adjusted over the ends, and they are packed in dated cardboard boxes. Catgut is similarly tested, and for sterilisation is first boiled five hours in ether, dried for 48 hours in a water oven at 75° C. and then in a Cumol oven at 156° C. Rubber goods are analysed to ensure a sufficient percentage of india-rubber: tubing must have 60 per cent. except drainage tubing, which need only have 50 per cent. Indiarubber rings must not be used to seal up preserved provisions, as weakly acid solutions dissolve from them slowly some of the barium and zinc which they contain. Rubber plasters are made in this depôt. They remain serviceable longer than those usually sold, and besides they are known to contain no substance that can harm a wound. Tinned mess utensils are examined to see they have been made according to law. Absorbent cotton is stated to be more absorbent if it contains some free fatty acid, but not more than ½ per cent. is allowed. Endeavours have been made to find some way of preventing the rusting of steel instruments, so far without success. This is a very interesting pamphlet which we commend to all officers in charge of stores. They will find it of great value.

[1] Das Königliche Hauptsanitätsdepot in Berlin. Berlin: A. Hirschwald. Pp. 38. 3 plates and 24 illustrations. Price 2 marks.

THE NEW NAVAL MEDICAL SERVICE REGULATIONS.

In connexion with the revised regulations for the Naval Medical Service directions have been issued by which surgeons under eight years' seniority, who have passed the necessary examination for staff-surgeon, may accept the new regulations, without prejudicing any chance of special promotion which they may possess under the old regulations, on account of appointments held in civil hospitals prior to their entry into the Navy. Surgeons under eight years' seniority who have already passed the examination for staff-surgeon under the old conditions will not be permitted to be re-examined under the new conditions.

DEATHS IN THE SERVICES.

Colonel W. Pleace Warburton, C.S.I., late I.M.S., at Lowestoft, recently, aged 68. He joined the Indian Medical Service in 1866, and for the greater part of 33 years' service he was engaged in administrative work. For some time he was medical officer to the Raja of Kapurthala, and in 1894 became Principal Medical Officer and Sanitary Commissioner of Assam. Later he was appointed Inspector-General of Civil Hospitals in the United Provinces. He recently vacated the post of Superintendent of the Edinburgh Royal Infirmary, a position which he had held since 1899.

Inspector-General of Hospitals and Fleets John Breakey, R.N. (retired), on Oct. 21st. He was appointed surgeon in 1854, staff-surgeon in 1863, fleet-surgeon in 1876, deputy inspector-general in 1882, and inspector-general in 1886. He was assistant surgeon of the *Penelope* during the Russian war in the Baltic in 1854, and was present at the bombardment of Bomarsund (Baltic medal). He also served in the China war of 1857–58 (China medal). In 1887 he was appointed inspector-general of Haslar Hospital. He retired in 1889.

The King has given to Captain Geoffrey Wallace Grainger Hughes, Royal Army Medical Corps, His Majesty's Royal licence and authority to accept and wear the insignia of the Fourth Class of the Imperial Ottoman Order of the Medjidieh, which has been conferred upon him by His Highness the Khedive of Egypt.

Lieutenant-Colonel Sir R. Havelock Charles, Serjeant-Surgeon to the King, will accompany the King and Queen on their Indian tour. Their Majesties' Indian suite will include Lieutenant-Colonel Bird, I.M.S., as extra surgeon.

Major Gilbert, I.M.S., has been appointed Surgeon to the Governor-Designate of Madras, Sir Thomas Gibson-Carmichael.

DONATIONS AND BEQUESTS.—Under the will of the late Mr. Daniel Myers the London Hospital will receive £1000 for the endowment of a bed in memory of the testator's wife. By the same will £500 are bequeathed to Guy's Hospital and a like sum to the Jews' Hospital and Orphan Asylum, West Norwood, and £300 each to the Jews' Deaf and Dumb Home; the Home and Hospital for Jewish Incurables, Tottenham; the Metropolitan Hospital, Kingsland-road; the North-Eastern Hospital for Children; the East London Hospital for Children; the Hospital for Sick Children, Great Ormond-street; the City of London Hospital for Diseases of the Chest; the Cancer Hospital; the Royal Free Hospital, Gray's Inn-road; the Middlesex Hospital; University College Hospital; St. Mary's Hospital, Paddington; and the Poplar Hospital; and £200 each to the Metropolitan Convalescent Institution and the Baroness de Hirsch Convalescent Home, Hampstead Heath.—An anonymous donation of £500 has been received by the treasurer of the Bristol Eye Hospital.—The Middlesex Hospital Cancer Charity has received from Mr. and Mrs. Richard R. Hollins a further donation of £100 for the maintenance of the "Richard Hollins" Cancer Research Scholarship.

Correspondence.

"Audi alteram partem."

THE NATIONAL INSURANCE BILL.

To the Editor of THE LANCET.

SIR,—It is becoming more evident every day that our profession is to be not merely revolutionised but victimised. The Chancellor is acting with perfect straightforwardness in emphasising the two plain offers he is making to the public—viz.: (1) 9*d.* for 4*d.*; and (2) the best of doctoring in *all* illnesses without any bills to pay.

We may safely leave to politicians to consider the arithmetic of his first offer. The second only concerns us, and the prominence always given to it in his fascinating popular addresses shows that he attaches very great importance to it as a consideration in voting, and as an inducement to swallow his gigantic Bill whole. We as a profession are bound to examine carefully the *finance* of this offer, which touches us so closely, and it is our duty, as the interested parties, to follow the Chancellor's example by translating it into those terms of currency which will at once explain to the working man the gigantic money value of the boon he is offering on behalf of our profession, and at the same time enable ourselves and the public to understand its true cost, which must be met either by our profession or by the public purse.

Remembering, as its author has clearly indicated, that his scheme is ultimately to be extended to the entire family (say averaging five persons), what is his offer? He says in effect, "Not only will I give you 9*d.* for 4*d*, but I will also give you in medical aid, for 1*d.* to 5*d.* a week, what you have hitherto paid 1*s.* to 5*s.* for." We may fairly average up the annual doctor's bill, at current rates, of a householder earning £160 a year at from £2 12*s.* to £13 per annum, according to the amount of serious sickness occurring. This figure may probably for the future under the Bill be put far higher, for it is not the hitherto average bill incurred for serious sickness only that is to be paid, but a far larger account for attendance in *all* illnesses, great or small; and it is the small and numerous illnesses which under his proposals will be by far the largest total item in the bill. Now, why has he not, so far, put this offer also in plain figures?

First, because the sum is so incalculable that it cannot be estimated in advance or put in nutshell form. Second, because the sum is so gigantic that it cannot be provided by Parliament, and he has therefore arranged that it is to be provided by our profession, in sweat and toil, through its acceptance of a system of contract *per capita* payment; in effect, this badly financed scheme requires underwriting, and *we* are to underwrite the gigantic insurance risks of the Chancellor's experiment. Payment per attendance for services rendered, which has hitherto been the very bedrock of our free profession, has been scouted by politicians and even shirked by some of ourselves, *solely* because it does not fit in with the Chancellor's promises and the Parliamentary Budget. It is freely granted that it does not, owing to the inconceivable extravagance of those promises. But this leaves our profession on the horns of no dilemma save this: of either saving the Chancellor's reputation at our own expense in incessant sweated and degraded work, or of washing our hands honestly of his Bill. Accepting the dilemma, which alternative do we elect?

Our leaders (according to the most far-seeing observers in your columns) have hardly emerged with credit from the first round of the fray in which they deliberately elected to tackle the Chancellor on his own chosen ground with their hands tied behind them by the so-called "principles" of his Bill. Is it not time for those of us—I believe an overwhelming majority—who intend to stand by the present free basis of our profession *at all costs* to say so openly? *I hereby declare that on no consideration will I accept the transforming of my practice into a contract per capita basis.* I invite you, Sir, to open your columns to receiving the names of those who adhere to the above declaration. Once a beginning is made a few hundreds of declared adherents—the more the stronger—will give heart to our whole profession, and by establishing a vanguard of stalwarts strengthen the hands of our "negotiators"; and, what is of far more importance, enlighten public opinion, both in and out of Parliament, as to our real intentions—viz., to stand inflexibly by the old flag of freedom under which we have hitherto lived secure, and which cannot fall save by our own acquiescence. The reasons for the faith and determination that are in certain of us are so numerous, and the aspects of the question so many sided, that it would be impossible to elaborate them here. Suffice it to say that they have, one and all, been convincingly demonstrated in most able letters to the press; and that they are, one and all, based not merely upon private interests, singly or as a profession, not merely upon ordinary justice and freedom of contract, upon ordinary relations of work to pay, but fundamentally upon the real interests of the public and of the poor, when these interests are seriously examined without political or electoral party bias.

Many members of the medical profession remain entirely unconvinced by the able but unpractical arguments raised by some few idealists in our profession in favour of a universal State medical service. These arguments have naturally been used by the Chancellor's adherents as in some measure conferring the approval of our profession on his scheme for substituting a universal contract system for the free practice under competitive conditions which ought to be adhered to without compromise. This *per capita* system is fundamentally immoral, dishonest, and demoralising to both doctor and patient.

Those who think in this manner in no way set themselves against any reasonable plan of enlisting their aid in a scheme of national insurance for the poor. But this is not the time or place for elaborating proposals, based on *totally different principles* from those of the present Bill, which cannot by any ingenuity be amalgamated or engrafted on that Bill. We do not, under any circumstances, intend to try to pour new wine into old bottles. Nor do we intend to allow our interests to be destroyed by the passing of the Bill in a hurry in a month's autumn session. Why should we? The present is, in all probability, the psychological moment which will make or mar us; it is manifest to all who discern the signs of the times in politics that the present is the moment when our intentions should be honestly declared.

Will you, as a medical statesman, take this opportunity of gauging the opinion of the profession by inviting the signatures of all who agree with my declaration, so as to form at least a body of declared and deliberate intention which the interests of the public require should become known?

I am, Sir, yours faithfully,

Osmotherly, Northallerton, Oct. 20th, 1911. H. B. LUARD.

*** We have from the beginning deplored the acceptance by the medical profession of the incalculably wide extension of the contract system proposed under the National Insurance Bill. Under this system much harm has already been done to professional and scientific work. But it is understood that a majority of the medical profession has given adherence to the principle and now only remains in doubt whether the terms upon which that adherence has been promised can be obtained. Were this not so, we should consider it even now not too late to urge on our readers the dangers of contract practice.—ED. L.

To the Editor of THE LANCET.

SIR,—The promoters of the National Insurance Bill seem to have decided that the simplest way to deal with the medical profession is to ignore its claims; the Bill is to be rushed through Parliament, and the Government will take its chance of finding sufficient medical men to make a start with the work. Unfortunately, the profession has missed a great opportunity of refusing absolutely to recognise the contract system; but we can save the situation even now if we will only name our terms and stick to them.

The people are promised adequate medical attendance under the Bill. Now no professional man should be expected, except as an act of charity, to see a patient and supply drugs for less than half-a-crown each visit or

consultation. If we take eight as the average number of visits and consultations per annum for each person, £1 a year would be the corresponding remuneration. If then there must be a capitation fee let us fix it at 20*s.*, and not a penny less. "Absurd on the face of it" will be the reply. Quite so; in other words the Act can only be worked as a colossal charity financed by ourselves. We can also refuse to give way on the £2 a week income-limit. If we adhere resolutely to these two demands the Bill will, it is true, be unworkable, but the responsibility will not rest with us.

I am, Sir, yours faithfully,

EDWIN SMITH, M.D. Lond., Barrister-at-Law,
Lecturer on Forensic Medicine at St. Thomas's Hospital.
London, S.W., Oct. 24th, 1911.

To the Editor of THE LANCET.

SIR,—There is one point of importance in connexion with the Insurance Bill which, so far as I am aware, has not been raised, and that is the responsibility for the treatment of venereal diseases. Section 13 (4) of the Act, referring to diseases or disablement caused by misconduct of the person claiming the benefit, expressly states that whatever else be withheld, "such person shall nevertheless continue to be entitled to medical benefit." Unless the exact position of persons suffering from venereal diseases is settled in black and white before the Act is passed, the medical profession will find itself in a difficult position at a later date.

It is hardly fair to the profession that the treatment of venereal diseases, spread over a long period as it often must be, should be included in the contract, and yet it is of paramount importance to the public that such diseases should be efficiently treated. In the case of tuberculosis a considerable sum of money is set aside for its prevention and cure, and the responsibility for an excessive amount of certain diseases can be brought home to those responsible for it—Clause 46. Sooner or later the question is sure to be raised whether the contributions of the well-behaved are to be appropriated for the benefit of those who contract diseases while in pursuit of their own vicious pleasures. Then we may be faced by an outcry for prevention of venereal diseases by regulation or otherwise.

I am, Sir, yours faithfully,

London, S.W., Oct. 24th, 1911. A. GORDON WILSON.

To the Editor of THE LANCET.

SIR,—I would suggest that all medical men holding club appointments which at present are open to anyone to join should on a fixed date give notice to terminate their appointments by Dec. 31st. Otherwise there may be a way to pass the Insurance Bill and leave the clubs alone to find their doctors. Hence there would be a rush of well-paid artisans defeating our very chief object. This step would also assure the outside world that we do not intend to be defeated. We should, before re-accepting club appointments, stringently act on our united points and remove from our list any person violating our requirements. Even if here and there we have defections we can hold our own easily in the main. Mr. Lloyd George, I suspect, will drop the medical part of his Bill and leave the clubs to fight it out. Unless we resign we must accept unfit persons who will pour in on the Bill becoming law.

I am, Sir, yours faithfully,

Ewyas Harold, Hereford, Oct. 23rd, 1911. LESLIE THAIN.

To the Editor of THE LANCET.

SIR,—In the letter of Mr. A. Benthall on the above subject which you publish in your issue on Oct. 14th, p. 1093, he says, among other things, that "the suggestion of payment by fee for each attendance is a delightful dream, but utterly Utopian and out of the range of practical politics." I should like to ask if Mr. Benthall has ever heard of the National Deposit Friendly Society where the "dream" is put into very practical politics. If not, I should advise him to send for a copy of the rules of that society.

I am, Sir, yours faithfully,

Bangor, Oct. 22nd, 1911. RICHARD WILLIAMS.

THE RELATION OF THE ORGANIC PHOSPHORUS CONTENT OF VARIOUS DIETS TO DISEASES OF NUTRITION, PARTICULARLY BERI-BERI.

To the Editor of THE LANCET.

SIR,—Adverting to an annotation which I contributed to THE LANCET of Oct. 14th, and to an objection to one of my statements raised by Dr. H. Fraser in his letter published in your columns of Oct. 21st, I beg to explain that in the process of revising my original communication I inadvertently deleted the words "and aleurone layer" after pericarp. The statement was intended to read: "The disease as it occurs in the Far East, is now generally recognised to be due to a dietary of white rice from which the pericarp and aleurone layer (containing the bulk of the phosphates and other salts) have been removed in the process of 'polishing' or milling." I regret that the unfortunate omission of the words above mentioned led to the mistake pointed out by Dr. Fraser. Like all others interested in the subject of beri-beri, I am well acquainted with his published works and with the valuable investigations which he and his collaborator Dr. Stanton have made, and which have done so much to elucidate the etiology of this disease.

Whether, as some contend, the absence of a sufficiency of organic phosphorus in the dietary is the essential cause of beri beri, or whether, on the other hand, it is due to the presence or absence of some subtle compound in the diet as yet unknown, it can nevertheless be affirmed without hesitation that, thanks largely to the work of Fraser and Stanton, the disease can be prevented where rice is the staple article of diet, if care be taken to supply a kind from which certain essential qualities have not been removed by a process of over-milling.—I am, Sir, yours faithfully,

Oct. 23rd, 1911. THE WRITER OF THE ANNOTATION.

To the Editor of THE LANCET.

SIR,—As the chemical part of the work on this subject, recently published by Dr. Simpson and Mr. Edie, was carried out in the University of Liverpool and I have followed the whole of it, I may perhaps be allowed to reply to some of Dr. Fraser's criticisms in THE LANCET of Oct. 21st.

The monograph by Schaumann criticised by Dr. Fraser is, in my opinion, one of the finest masterpieces of scientific work—collating, as it does, the labours of very many workers—which I have ever seen in any language, and it would be a great pity if any simple error, such as ascribing the active principle to the phospho-protein group, should deprive Schaumann of the credit of clearly and emphatically pointing out the close relationships of a large group of nutritional disorders. The study of these diseases is of national importance not only to India and the East, but to our own nation and all Western civilisation. As early as 1896 Eijkman in Batavia had shown that fowls fed entirely on polished rice suffered and died from polyneuritis. Grijns in 1908 confirmed this, and Holst and Frohlich in Christiania in a lengthy series of researches on pigeons and guinea-pigs clearly showed that beri-beri and scurvy arose from the restrictions of diet.

Bradden in India first pointed out that tropical beri-beri was prevalent in those Eastern tribes and races, e g. Chinese, who used a highly milled rice as their staple diet, but did not occur in races such as the Tamils, who cured their rice in such a way that the pericarp and sub pericarpal layers were not removed from the grain in the process of milling. There is no question of the value of the experimental confirmation of this obtained in asylums and in gangs of compound labourers in India by Fraser and Stanton, and others. The workers here have highly appreciated their work, which attracted the attention of Professor Ross and formed the starting point of the experimental researches initiated in consequence and still proceeding.

Dr. Fraser chooses to be very severe when he states that our experiments here add nothing to our knowledge of the subject, but we did think that we had served some good purpose in drawing public attention in England to the probability that the problems of nutrition of infants and children were closely allied in type to beri-beri. We still persist in believing that the experiments of Hill

and Flack, and our own, form a conclusive proof of this position.

In regard to the chemical nature of the substances in the subpericarpal layers which are responsible for the activity we agree with Dr. Fraser that this is a question for the physiological chemist. That the substance is not a protein and does not contain phosphorus has been shown by the extremely interesting and elaborate experiments of the workers of the Bureau of Science of the Government of the Philippine Islands, Messrs. Chamberlain and Vedder. These observers have shown that the active material can be extracted from the rice-meal by alcohol and then dissolved in water. A daily ration of the filtrate, 10 c.c., added to polished rice not only prevented polyneuritis, but cured it after it had been induced. This ration contains only 0·16 milligramme of phosphorus pentoxide, so that it is fairly certain that the active substance is not a phosphorus-containing body. The amount of nitrogen in the filtrate is somewhat greater, being 0·04 per cent., in about 2 per cent. of total solids; this nitrogen would represent (if all protein nitrogen) in the daily ration 0·024 gramme of protein. So that it is extremely unlikely that the active substance is protein in nature.

But this casts no discredit on the views of Schaumann or anyone else. At an earlier date Fraser and Stanton themselves pointed out the close relationship between poverty in phosphorus and neuritis-producing properties in a food. Association of the active substance with organic phosphorus is all that is stated in the paper by Simpson and Edie, who say that: "We hope in a future contribution to give the results of our attempt to isolate the active principle, whether it be one of the organic phosphorus compounds or a substance which associates itself with these in its reactions, as do ferments with nucleo-proteids."

This investigation has been continued and is yielding most interesting results. We have clearly confirmed the results of the observers in the Philippines, and have saved pigeons, almost at the point of dying from polished rice diet, with extracts prepared by their methods, and containing practically no phosphorus and very little nitrogen. We now consider it most probable that the active substance is a glucoside, probably a galactosan, which reduces Fehling solution after, but not before, hydrolysis with acids. Such bodies are already known to exist in the subpericarpal layers and are termed hemi-celluloses by botanical chemists; they also occur in the cell-wall of the yeast plant, which, it will be remembered, is very efficacious in preventing polyneuritis from polished rice, and they are found under the peel of the potato in the layer usually given with striking benefit in infantile scurvy. We have shown that this material in the potato is still active in the treatment of infantile scurvy, even after heating for some hours to 120° C. in the autoclave, in this respect differing from the active material of rice-meal, which is destroyed by prolonged autoclaving, but not by boiling. The comparative thermostability of these active bodies is compatible with a glucosidal nature, but to a large extent against their being protein in character.

I am, Sir, yours faithfully,

BENJAMIN MOORE.

Bio-Chemical Laboratory, The University, Liverpool, Oct. 23rd, 1911.

THE GENERAL MEDICAL COUNCIL AND THE IDENTIFICATION OF REGISTERED PRACTITIONERS.

To the Editor of THE LANCET.

SIR,—It has been observed in a report of the inquest on the body of Mrs. Gorringe in connexion with which reference is made to Mr. Charles Louis Lumley, a practitioner whose name was struck off the Medical Register by order of this Council in 1900, that the coroner, Mr. Troutbeck, is stated to have said: "It was difficult for a doctor to ascertain whether a man, obviously with medical knowledge, was on the Register." If the coroner is correctly reported, he is under a misapprehension.

The preamble of the Medical Act, 1858, begins as follows: "Whereas it is expedient that persons requiring medical aid should be enabled to distinguish qualified from unqualified practitioners." I am directed to say that the Council is most anxious to carry out the primary duty imposed upon it by this Act, and a similar duty imposed by the Dentists Act, 1878. It is always willing, and indeed anxious, to give information to public officials, to registered practitioners, and to the public in all cases in which there is any doubt as to whether a person is or is not a registered medical practitioner or dentist. Inquiries are constantly made by telegram, by telephone, or in person, and they are always promptly attended to. In consequence of minute differences in names, and of practitioners making use of names or compound names other than those by which they are registered, it is preferable that inquiries should be made in writing; but in cases of emergency they can be made orally, and the public may be assured that all the means at our command will be made use of to afford them the fullest information.

Copies of the Medical Register, which is the only official list of registered practitioners and which can be obtained through any bookseller, are distributed by the Government to coroners, law and county courts, and various public offices. Moreover, every medical practitioner on completing his first registration is entitled to receive a copy from the Council on application.

I am, Sir, yours faithfully,

NORMAN C. KING,
Acting Registrar, General Council of Medical Education and Registration of the United Kingdom.

299, Oxford-street, W., Oct. 19th, 1911.

MEDICAL EQUIPMENT FOR MERCHANT SHIPS.

To the Editor of THE LANCET.

SIR,—It is with great pleasure that we learn of the prominence which you have given to the recommendation of the Departmental Committee of the Board of Trade on "Ships' Medicine Chests," relative to the need for separate and reserved accommodation in merchant ships for members of the crew who have fallen ill or have been injured.

Your very cordial endorsement of this recommendation is most sincerely appreciated by us, and must exercise considerable influence in Government departmental circles. There is, however, one point in connexion with the comments on this recommendation which occurs to us as open to considerable question. In trusting that the Board of Trade will adopt the recommendation, you state that it would involve the provision, *adjacent to the officers' cabins*, of a spare cabin definitely allocated as a hospital and so marked. According to our views a hospital of the kind should be isolated as far as possible, consistent, of course, with it being in every way convenient for the purpose of efficient and proper treatment of those lodged in such a hospital. That it should be "adjacent to officers' cabins" would, on the face of it, appear to be highly inadvisable, as tending all the more to the risks of contagion and infection, whereby those responsible for the safety of a ship would be subjected to very serious danger, for which there does not appear to be any adequate reason whatever. Moreover, officers' cabins nowadays are very rarely lodged in the "after part of a ship," and the provision of ships' hospitals, if this recommendation is adopted by the Board of Trade, as we hope it will be, will necessarily depend on the plans and arrangements of the particular ships, of which there are so many different classes and types in the Mercantile Marine.
